ALEXANDER COZENS (c. 1717-1786) was born in Russia, the son of Richard Cozens, shipbuilder to the tsar. He settled in England after visiting Rome in 1746, and became a fashionable drawing master. William Beckford was his pupil and has preserved almost all that is known of his personal characteristics. His fondness for systematization found expression in many publications for artists. *A New Method of Assisting the Invention in . . . Landscape* advocated the free manipulation of ink for suggesting compositions, and his own "blots" done in this manner are among his most effective drawings. He exercised considerable influence on English water-colour drawing. His own work was carried out almost exclusively in monochrome washes, but he achieved breadth and atmospheric effect. He died in London on April 23, 1786. The British museum's collection of his works includes 53 drawings lost by him when returning from Italy, which his son recovered in Florence 30 years later.

JOHN ROBERT COZENS (1752-1797), son of Alexander Cozens, was born in London and began to exhibit drawings with the Society of Artists at the age of 15. The two long visits he paid to the continent, during 1776-79 and 1782-83, were the formative and decisive events in his career. On the first occasion he traveled through Switzerland to Italy, it is said as draftsman to the antiquary Richard Payne Knight, and spent much time in Rome. His second visit was made with William Beckford, whom he accompanied as far as Naples. Cozens became insane in 1793, and spent the remainder of his life under the care of Thomas Monro, an alienist, also known as a collector and amateur draftsman. He died in London in Dec. 1797.

Cozens found the subject matter of his art in the Alps and the Roman Campagna. Painting in low-toned combinations of blue, green and gray water colour, he evoked from these wild scenes, charged with historical associations, a haunting and sometimes melancholy poetry. T. Girtin and J. M. W. Turner, by copying his works in their early years, first learned from him the full range of water colour as an expressive medium. The British museum has 37 and the Victoria and Albert museum, London, has 28 water colours by him.

See A. P. Oppé, *Alexander and John Robert Cozens* (1952). (G. Rs.)

**COZZENS, JAMES GOULD** (1903- ), U.S. novelist, who became a well-known literary figure in the late 1950s, was born in Chicago, Ill., on Aug. 19, 1903. He grew up on Staten Island, N.Y., and was educated there and at the Kent school, Kent, Conn., from which he graduated in 1922, and at Harvard, where he spent two years. While at Kent he had a piece accepted by the *Atlantic Monthly*, a feat of precocity that he more than matched during his sophomore year at Harvard by publishing his first novel. During a year's teaching in Cuba he accumulated background material for *Cockpit* (1928) and *The Son of Perdition*

(1929). Cozzens first realized some acclaim in 1931, when his novella *S.S. San Pedro* won the Scribner's prize. Thereafter he published increasingly complex and able novels, most of which deal with human reverberations of the professions that his major characters practise. Thus, *The Last Adam* (1933) deals with a doctor, *Men and Brethren* (1936) with an Episcopalian minister, *The Just and the Unjust* (1942) and *By Love Possessed* (1957) with lawyers and *Guard of Honor* (1948) with officers and men at an army air force base in Florida.

Although Cozzens won the Pulitzer prize for *Guard of Honor*, he did not become a popular author until the publication of his most pretentious work, *By Love Possessed*, which not only garnered prizes and immense sales but became the centre of a critical controversy about the influence of Cozzens' conservative ideas on his former obscurity and later success. Perhaps the chief benefit of the controversy was that it led to reprintings and wider reading of his most important novels, *Men and Brethren*, *Ask Me Tomorrow* (1940) and *Guard of Honor*. (R. G. St.)

**CRAB**, a name applied to the short-tailed decapod Crustacea, the Brachyura, and to other forms, especially of the section Anomura, which may resemble them in appearance and habits. Brachyurans, or true crabs, are distinguished from the long-tailed lobsters and shrimps by the small abdomen or "tail," folded up under the body.

**Distribution and Natural History.**—Most crabs live in the sea; even the land crabs, which are abundant in tropical countries, visit the sea occasionally and pass through their early stages in it. The river crab of southern Europe, the Lenten crab (*Potamon edulis*), is an example of the fresh-water crabs that are abundant in most of the warmer regions of the world. As a rule, crabs breathe by gills, which are lodged in a pair of cavities beneath the sides of the hard shell, or carapace, but in the true land crabs the cavities become enlarged and modified so as to act as lungs for breathing air.

Walking or crawling is the usual mode of locomotion, and the peculiar sidelong gait familiar to most people in the common shore crab is characteristic of most members of the group. The crabs of the family Portunidae, and some others, swim with great dexterity by means of their flattened paddle-shaped feet.

Like many other Crustacea, crabs are often omnivorous and act as scavengers, but many are predatory in their habits and some are content with a vegetable diet.

Though no crab, perhaps, is truly parasitic, some live commensally with other animals. Examples are the little pea crabs (Pinnotheridae), which live within the shells of mussels and other bivalve mollusks and share the food of their hosts, and the coral-gall crabs (Haplocarcinidae), which irritate the growing tips of certain corals so that they grow to enclose the female in a stony prison from which there is no escape. Many of the sluggish spider crabs (Majidae) cover their shells with growing seaweeds, zoophytes and sponges, which afford them a very effective disguise.

The giant crab of Japan (*Macrocheira kaempferi*) and the huge Tasmanian crab (*Pseudocarcinus gigas*) are two of the largest known Crustacea. Among the smaller brachyurans are the so-

BY COURTESY OF MARINE STUDIOS, MARINELAND, FLORIDA

FIG. 1.—LARGE HERMIT CRAB (*PETROCHIRUS DIOGENES*) IN A WHELK SHELL

called mud crabs of the family Xanthidae, which are seen on the seashores in most latitudes.

Better known anomuran crabs are the hermit crabs that live in empty shells of gasteropod mollusks, which they carry about with them as portable dwellings. As the crab grows it changes its abode from time to time, often having to fight with its fellows for the possession of an empty shell. In tropical countries the hermit crabs of the family Coenobitidae live on land, often at considerable distances from the sea, to which they must return to hatch out their spawn. The large robber or coconut crab of the Indo-Pacific islands (*Birgus latro*), which belongs to this family, has given up the habit of carrying a portable dwelling, and the upper surface of its abdomen has become covered by shelly plates.

**External Features and Development.**—In most brachyurans the body is transversely oval or triangular in outline, more or less flattened and covered by the carapace. There are five pairs of legs. The first pair end in pincers or chelae and are usually much more massive than the others, which are used in walking or swimming. The eyes are set on movable stalks and can generally be withdrawn into sockets in the front part of the carapace. There are six pairs of jaws and foot-jaws (maxillipedes) enclosed within a "buccal cavern," the opening of which is covered by the broad and flattened third pair of foot-jaws. The abdomen is usually narrow and triangular in the males, but in the females is broad and rounded and bears appendages to which the eggs are attached after spawning.

As in most crustaceans, the young of nearly all crabs, when newly hatched, are very different from their parents. The first larval stage, known as the zoea, is a minute transparent organism, swimming at the surface of the sea. It has a rounded body, armed with long spines, and a long segmented tail. The legs are not yet developed and the foot-jaws form swimming paddles. After casting off its skin several times as it grows in size, the young crab passes into a stage known as the megalops, in which the body and limbs are more crablike, but the abdomen is large and not folded up. After a further molt the animal assumes a form very similar to that of the adult. There are a few crabs, especially those living in fresh water, that do not pass through a metamorphosis but leave the egg as miniature adults.

**Economic Importance.**—Many crabs are sought as food by man. The most important and valuable are the edible crab of British and European coasts (*Cancer pagurus*), the blue crab (*Callinectes sapidus*) of the Atlantic coast and the Dungeness crab (*Cancer magister*) of the Pacific coast of North America. The *Cancer* crab fishery of Europe ranks next in importance to its lobster industry. The crustacean fisheries of India outweigh in quantity and value the yield of all other fisheries of that country, the crabs being outranked only by the shrimps in importance. The swimming crabs, *Scylla* and *Portunus*, related to the American blue crab, are among the most important sources of sea food throughout the entire Indo-Pacific region. *Scylla serrata* reaches a large size, 8 to 12 in. in width, exceptionally 18 in. in the brackish waters of Chilka lake, India. Commercially valuable Anomura are the lithodid (literally "stone") crabs, of which the so-called king crab (*Paralithodes camtschatica*) of Japan, the Bering sea, and Alaskan waters is the most important.

Crabs are usually caught in baited traps or "pots," but the blue crab of the American Atlantic coast is frequently taken on baited lines, and the king crab fishery of the North Pacific employs trawling vessels, accompanied by factory ships to which the catches are transferred for immediate freezing or canning.

FIG. 2.—FIDDLER CRAB (*UCA PUGNATOR*): (TOP) FEMALE; (BOTTOM) MALE DISPLAYING ITS CLAW IN COURTING THE FEMALE

**CRAB APPLE**, the name applied to the fruits or plants of various species of *Malus*, the apple genus; also to certain crosses of such species with improved cultivated types, which give small-size tart fruits. The genus *Malus*, the apples (included by some botanists in *Pyrus*, the pear genus), includes approximately 25 species indigenous in temperate regions of North America, Europe and Asia. In general, they resemble the cultivated apple in flowers and foliage but have more slender trunks, stiffer and more or less spiny branches, and much smaller, usually very acid fruits. They are extensively used as ornamental shrubs or small trees, of which many horticultural varieties exist. The blossoms, white to pink and carmine, of many of the crab apples are extremely showy in the spring, and many species of crab apple are characterized by brightly coloured fruit that may hang on well into the winter. Crab apples most widely used as ornamentals include *Malus spectabilis*, the Chinese flowering crab; *M. baccata*, Siberian crab; *M. sieboldi*, Toringo crab; *M. floribunda*, the Japanese flowering crab; and *M. pumila* var. *niedwetzkyana*, the redvein crab.

The American crab apples include the following: *M. coronaria*, indigenous from western New York and southern Ontario to Wisconsin and southward to North Carolina and Missouri, a beautiful tree when in blossom in April or May and cultivated to some extent as an ornamental. The fruit is delicately scented but very acid, 1 to 1½ in. in diameter.

*M. angustifolia*, the southern crab apple, is native from southern Virginia to southern Illinois and southward to Florida and Louisiana. It produces fruit three-fourths to one inch in diameter. *M. ioensis*, the prairie crab apple, is indigenous from Wisconsin and Minnesota southward to Nebraska, Kansas and Missouri. The Oregon crab apple, *M. fusca*, is found along the Pacific coast from Alaska to California. The fruit is oblong, one-half inch or less in diameter.

ROCHE  
FLOWERS AND FRUIT OF JAPANESE FLOWERING CRAB APPLE (MALES FLORIBUNDA)

Fruits of all the crab apples may be used for jelly and other culinary purposes. The Siberian crab is rather widely grown for fruit, which is used mainly for jelly and for preserving and pickling. Most of the crab apple species can be crossed with standard apple varieties and many such crosses have been made, particularly in Canada, to secure very hardy, early ripening apples adapted to severe weather conditions. In general, the progeny are intermediate in size and quality between the parents.

In Europe many horticultural varieties producing small, highly acid fruit are grown primarily for cider making and are commonly referred to as crab apples or cider apples. Many of these may have originated as crosses between the *Malus* species and cultivated apples. They represent a large proportion of the apple production, particularly of France.

**CRABBE, GEORGE** (1754–1832), one of England's finest writers of verse-tales, a poet who handled with skill and imagination the realistic details of life. Born on Dec. 24, 1754, at Aldeburgh, Suffolk, where his father was a customs officer, Crabbe became a doctor's assistant, and set up his own practice in Aldeburgh in 1775. But he was not successful, and so in 1780 he

borrowed £5 and went to London. He had already published a poem *Inebriety* in 1775, but neither this nor *The Candidate* (1780) brought him any fame. In 1781 he wrote a desperate letter to the statesman Edmund Burke. Burke acted at once; he read Crabbe's compositions, selected a descriptive and didactic poem, *The Library*, and persuaded James Dodsley to publish it in 1781. In the same year Burke used his influence to have Crabbe accepted for ordination, and after a few months as curate at Aldeburgh, in 1782 Crabbe became chaplain to the duke of Rutland at Belvoir castle.

In the next year, Crabbe published the first poem in which he really found his own voice, *The Village*. Dr. Johnson, who read the manuscript and suggested a few minor revisions, praised it as "original, vigorous, and elegant."

*The Village* was in part a protest against Oliver Goldsmith's *The Deserted Village* (1770), which was thought by Crabbe to give too sentimental and idyllic a picture of country life. Crabbe had resolved to tell the truth: "I paint the Cot, As Truth will paint it, and as Bards will not." He was perhaps the first to express with vigour and seriousness the dissatisfaction which many 18th-century poets had felt at the sentimental pastoral. In *The Village*, Crabbe made good use of his detailed observation of humble life and of the grim countryside of his home. Already he had begun to earn Byron's description of him as "Though Nature's sternest Painter, yet the best."

Crabbe married Sarah Elmy in 1783. For more than 20 years after *The Newspaper* (1785) he published nothing, though he wrote a great deal. Then in 1807 he reprinted his poems, together with a new work, *The Parish Register*; its success led him to publish in 1810 *The Borough*. Both were long poems which incorporated verse-tales; and Crabbe evidently thought that he had discovered the right form for his talent, since his next work was *Tales in Verse* (1812). By 1819 his success had been such that John Murray, the publisher, paid him £3,000 for the copyright of the previous volumes and of his new *Tales of the Hall*, 2 vol. (1819). Crabbe's wife had died in 1813; and, after receiving several preferments, Crabbe was given in 1814 the living of Trowbridge, Wiltshire, his home till his death. He was now a famous figure, and he became acquainted with such leading literary men as Sir Walter Scott, Thomas Moore and Thomas Campbell. After a retired life in his later years, he died at Trowbridge, Feb. 3, 1832.

Crabbe is often, and rightly, called the last of the Augustans. He follows such Augustan poets as John Dryden, Alexander Pope and Dr. Johnson, in using for almost all his poems the heroic couplet. He handles this traditional instrument with great skill; and although he lacks Pope's brilliant wit, he has his own weighty shrewdness. His attitudes, too, are firmly Augustan. His moral judgments have much in common with the stern but humane outlook of Dr. Johnson; and it is not surprising that Jane Austen, in many ways another late Augustan, lightheartedly imagined herself as Mrs. Crabbe. But Crabbe is not merely what the parodist as Horace Smith called him, "Pope in worsted stockings." He had his own subject-matter—the distresses, miseries and guilt of ordinary daily life (and not merely the life of the well-to-do). In 1825, William Hazlitt, though he disliked Crabbe's "literal fidelity," described it in a neat paradox: "he assumes importance by a number of petty details; he rivets attention by being tedious." Hazlitt also saw that Crabbe's real strength lay in his psychological insight, his "intimate knowledge of the small and intricate folds of the human heart."

Earlier 18th-century poets such as Jonathan Swift and John Gay had made use of the realistic and even sordid details of life; and there had been a few realistic verse-tales, such as Soame Jenyns' *The Modern Fine Lady* (1751). But it was Crabbe who appreciated what riches there were in this vein, and who became the first poet since Chaucer to combine, in his tales, traditional moral attitudes with the compassion that comes from understanding of human character. To these endowments he added a gift for storytelling, and an excellent understanding of how to use language to mirror the minds of his characters. He also had great skill at adapting the heroic couplet to the reproduction of conversation and repartee.

Crabbe is unlikely to be again a widely popular poet, because of the narrowness of his range and his deliberate avoidance of the "poetic" and the lyrical. But his power and sturdy poetic skill can still make their impact, and, for example, led Benjamin Britten to adapt the story "Peter Grimes" into an opera. It is not surprising that Crabbe's poems have always won the praise of his fellow poets, from Wordsworth and Byron to Ezra Pound and T. S. Eliot.

**BIBLIOGRAPHY.**—The edition of Crabbe's *Works*, 8 vol. (1834) contains a *Life of the Rev. George Crabbe* by his son; this was reprinted separately in the *World's Classics* series in 1932. *Poems by George Crabbe* were ed. by Sir A. W. Ward, 3 vol. (1905-07); *New Poems* were ed. by A. Pollard (1960). See also R. Huchon, *George Crabbe and his Times*, Eng. trans. by F. Clarke (1907); L. Haddakin, *The Poetry of Crabbe* (1955). (C. B. R.)

**CRAB GRASS**, or finger grass, the common names for various species of *Digitaria*, especially *D. sanguinalis* and *D. ischaemum*, both natives of Europe widely naturalized as weeds in North America. Both of the above species and a few closely related ones become very troublesome weeds in lawns and on agricultural land because they have decumbent stems that root at the joints. Such a habit, in spite of their being annual grasses, makes eradication difficult, especially if they have seeded into existing lawns.

Rooting at the joints, even in the face of constant mowing, makes thickset patches of the weed, and mowing merely induces new flowering and fruiting spikes that shed their prolific seed and infest the ground for the succeeding season.

Since crab grass is an annual, the only means of perpetuation is by seeds that overwinter in the ground, usually in great quantity. Generally, in ordinary temperate climates, the seed germinates in May or June, distinctly later than the spring growth of good lawn grasses, and causes bare patches in lawns that were infested with crab grass the previous season. This relatively tardy germination suggested the use of so-called pre-emergence sprays, which kill only the seeds. Applied in late April or early May, 2,4-D will often (but not always) kill these seeds without injuring desirable lawn grasses. Pre-emergence sprays do not give such good control as do post-emergence sprays, but in small areas they may kill off many seeds that would otherwise germinate. One reason for the partial ineffectiveness of 2,4-D is that in the temperate zone in late April or early May air temperatures are likely to be below 70°

BY COURTESY OF U.S. DEPARTMENT OF AGRICULTURE

CRAB GRASS

F., the temperature at which the compound is most effective.

Once crab grass has germinated it is essential to use post-emergence sprays designed to kill the crab grass but not other grasses. Three of them, in the relative order of effectiveness, are PMA (phenyl mercuric acetate); DSMA (disodium methyl arsonate), useful also for chickweed; and potassium cyanate. All should be used when the young seedlings are noticeable, and because none of them kill all seedlings, the treatment should be repeated two or three times in the summer.

After many years of experiment, authorities have concluded that the weed cannot be eradicated by chemicals alone. Seed will inevitably be carried in and become established, especially on poor soils that will not maintain a good lawn. The best remedy is to so improve the soil that a strong thick turf will smother the seedlings of crab grass long before their maturity.

**CRACKING PROCESS**, the thermal decomposition of petroleum to form more useful products. Cracking involves the use

of heat, pressure and catalysts and more than doubles the amount of gasoline obtainable from crude oil by the straight-run (boiling) method of distillation. See PETROLEUM; GASOLINE.

**CRACOW** (Pol. *KRAKOW*), a *województwo* (vovoidship) in southern Poland, bordering on Czechoslovakia. Pop. (1960) 1,990,359. Area 15,350 sq.km. (5,927 sq.mi.). Its southern region consists of the slopes of the Carpathian mountains. The high Tatra mountains, of granite and limestone, lie on the Czechoslovak frontier, their highest peak being Gerlach (8,711 ft.) on Slovak territory. The whole is a national park, as is the small Pieniny group with the picturesque Dunajec valley. North of the Carpathians lies the Sandomierz valley, watered by the Vistula river. Rich deposits of salt are found at the edge of the mountains and the valley. The Little Polish plateau extends on the left bank of the Vistula. In its western part there are coal deposits (a continuation of the Upper Silesian coal basin), as well as zinc and graphite ores. The limestone belt of the Cracow-Czestochowa plateau is a tourist area, while the Miechow area, north of Cracow, with its fertile soils, is agricultural. Woods covering 25.8% of the land provide for the timber industry (Klucze, Zywiec). Coal deposits and water resources supply power, and the second largest Polish power station is at Jaworzno. After World War II the iron and steel industry was considerably extended (Nowa Huta, in Cracow town), and an aluminum foundry was built at Skawina. Besides the metal industry, the chemical (Oswiecim, Tarnow), building materials, textile (Andrychow) and food (Cracow) industries were developed. The tourist industry owes its growth to the fine landscapes, mineral springs, parks and reserves, places of architectural interest and the extensive folk traditions, especially in the Tatra mountains.

The largest towns (pop., 1960) are Tarnow (q.v.; 71,000), Jaworzno (53,000), Nowy Sacz (q.v.; 34,000), Oswiecim (q.v.; 31,000), Zakopane (25,000), Chrzanow (21,000), Zywiec and Nowy Targ. (T. K. W.)

**CRACOW** (Pol. *KRAKOW*), a city in southern Poland, the former capital of the country and the seat of a Roman Catholic archbishop (from 1925), is the chief town of Cracow *województwo* but (from June 1, 1950) is a separate administrative unit. It lies 696 ft. above sea level, on both banks of the upper Vistula, 249 km. (155 mi.) S.S.W. of Warsaw. Pop. (1960) 481,296.

At the centre of Cracow is the old city, which was once moated and walled. Of the medieval fortifications, pulled down at the beginning of the 19th century and replaced by shady promenades (*planty*), only two towers of the 13th century, with the St. Florian's gate (1307) and the Barbican (1498), are left. At the heart of the old city is Market square (*Rynek*) with the Drapers' hall (*Sukiennice*), a Gothic edifice of the 14th century, converted in the 16th century to the Renaissance style and restored in the 19th century. From each side of Market square run three parallel streets, but their chessboard arrangement is interrupted by older buildings and by Grodzka street, which leads from Market square to the royal castle standing on the rocky hill of Wawel, on the left bank of the Vistula.

Traces of the oldest building site are to be found on Wawel hill, where the pre-Romanesque rotunda of Felix and Adaukt was discovered. The remains were also found there of two successive cathedrals. The present cathedral (the third) was started in 1320. Added to and decorated by succeeding generations, it constitutes a harmonious blend of styles. The Sigismund (Zygmunt) chapel (1530), built by Bartolomeo Berecci, stands out in the whole complex as a masterpiece of Renaissance architecture. The interior of the cathedral contains the tombs of Polish kings, national heroes and poets. A silver coffin holds the alleged relics of St. Stanislaw, patron saint of the Poles who, as bishop of Cracow, was slain before the altar by King Boleslaw II in 1079.

From an early period Wawel hill was the site of the prince's court. The present castle, begun in the 12th century, was successively enlarged by Casimir the Great and Sigismund I Jagiello, and was until the end of the 16th century the residence of the Polish kings. It has a 16th-century Renaissance-style courtyard which, with its three-storied arcades, is one of the finest and largest of its kind in the world. The restoration of the castle,

from 1846 an Austrian military barracks and hospital, was begun in 1905. Among its most precious ornaments are the 16th-century Flemish tapestries.

No other city in Poland has so many historic buildings. There are no fewer than 58 ancient churches, many of them containing famous works of art. The largest, and in many ways the finest, is that of Our Lady (13th-14th century) in a corner of Market square, a typical example of Polish Gothic. It contains stained-glass windows of the 14th century and a triptych by Veit Stoss. Sculptured in linden wood, it depicts scenes from the life of the Blessed Virgin. Seized and removed to Nürnberg by the Germans in 1939, it was returned to Poland in 1945 and replaced on the high altar of the church.

The university, the second oldest in central Europe, was founded by Casimir the Great in 1364. It is called Jagiellonian university after Wladyslaw Jagiello who transferred it in 1400 to the town parish of St. Ann's where it remained. The Collegium Maius, dating from the 15th century, is one of the few Gothic university buildings surviving in Europe. New university buildings were erected in 1883-87. The university library, completed in 1938, one of the largest in Poland, houses more than 1,000,000 volumes. Cracow also has ten other establishments of higher education, ten museums, nine theatres and an opera house.

Close to the city are four artificially built huge memorial mounds. Two of them date from the early middle ages: the first that of Prince Krak (or Krakus) was erected probably in the 8th century to the memory of the legendary founder of Cracow; the second to that of his daughter Wanda who allegedly chose to drown herself in the Vistula rather than marry a German prince. The other two mounds are modern: one was erected in 1823 in honour of Tadeusz Kosciuszko (q.v.); the other in honour of Jozef Pilsudski (q.v.) in 1937.

Cracow is linked with Warsaw by two railway lines, one of which (through Czestochowa) is electrified. Other lines lead north to Danzig, west to Wroclaw and Berlin, to Prague and (through Presov) to Vienna, south to Zakopane in the Tatra mountains and east to Lvov. There is also an airport (5.6 km. or 3½ mi. distant).

Situated on the medieval trade routes between central Europe and the Black sea and between southern Europe and the Baltic, Cracow early became an important commercial centre. Many handicraft and some industrial enterprises existed there in the late middle ages, but industrial expansion began after the restoration of Poland's independence in 1918. The erection of the Nowa Huta iron- and steelworks, started in 1949 on the territory of Mogila village, 10 km. (6½ mi.) to the east, with a modern settlement for 100,000 inhabitants, transformed Cracow into a considerable industrial centre. Within the boundaries of its new administrative area there are about 300 factories. The chemical, foodstuffs, printing, clothing, tanning, stoneworking and metallurgical industries are represented.

**History.**—Cracow, the political centre of the tribe of Wislanie (Vistulans), is thought to have been under Czech rule at one time, but about the year 1000 it was retrieved by Boleslaw I who made it the seat of a Polish bishopric. It became the capital of the most important of the principalities into which Poland was divided by King Boleslaw III in 1138. The city was practically ruined during the first Tatar invasion of Poland in 1241, but was soon rebuilt. In 1257 it received from Prince Boleslaw the Shy (Wstydiwy) "Magdeburg rights"; i.e., a civic constitution modeled on that of Magdeburg. The city passed through many vicissitudes until King Wladyslaw I, who reunited Poland, made it his capital in 1320 and from that time it remained the coronation and burial place of the Polish kings.

The transfer of the country's capital to Warsaw in 1609 reduced Cracow's political importance. After the Swedish wars of the 17th century Cracow was also impoverished economically. The anti-Russian insurrection, headed by Kosciuszko, started in Cracow on March 24, 1794. One year later the third partition of Poland took place and Cracow became Austrian, but in 1809 Napoleon incorporated it with the duchy of Warsaw. In 1815, at the Vienna congress, Cracow and the adjoining territory were formed into an independent republic (pop. 140,000; area 3,160 sq.km. [1,220

sq.mi.]), but in 1846 it was incorporated with Austria. At the conclusion of World War I Cracow was again a part of restored Poland. In World War II it fell to the Germans on Sept. 6, 1939. Hans Frank, the German governor of the occupied and truncated Poland, established his headquarters at the Wawel castle. On Nov. 6, 1939, he ordered the deportation of 186 professors and lecturers of the university to concentration camps in Germany where many of them died. Frank was also responsible for sending in March 1943 about 55,000 Cracow Jews to Oswiecim (Auschwitz) extermination camp. On Jan. 19, 1945, Cracow was liberated by Soviet army groups.

**CRADDOCK, CHARLES EGBERT** (1850-1922), the pen name of MARY NOAILLES MURFREE, U.S. author, who was born near Murfreesboro, Tenn., on Jan. 24, 1850. She was crippled in childhood by paralysis, but attended school in Nashville and Philadelphia. During her summers in the mountains of eastern Tennessee, she came to know the simple people there whom her writings portray. She contributed to *Appleton's Journal* and, first in 1878, to the *Atlantic Monthly*. No one, apparently, suspected that the author of these tales was a woman, and her identity was not disclosed until after the publication of her first volume of short stories, *In the Tennessee Mountains* (1884). She deals mainly with the narrow, stern life of the mountaineers left behind in the advance of civilization. Her work abounds in effective descriptions of scenery. Her later books are inferior to those written when the local-colour movement was at its height. She died at Murfreesboro on July 31, 1922.

See E. W. Parks, *Charles Egbert Craddock* (1941); F. L. Pattee, *A History of American Literature Since 1870* (1915).

**CRADLE**, a child's bed of wood, wicker or iron, with enclosed sides, slung upon pivots or mounted on rockers. It is a very ancient piece of furniture, and the date when it first assumed its characteristic swinging or rocking form is by no means clear. A miniature in an illuminated *Histoire de la belle Héloïse* in the Bibliothèque Nationale in Paris (end of the 14th or beginning of the 15th century) shows an infant sleeping in a tiny four-post bed slung upon rockers. In its oldest forms the cradle is an oblong oak box without a lid—originally the rockers appear to have been detachable—but, like all other pieces of furniture, it has been subject to changes of fashion alike in shape and adornment. It has been panelled and carved, supported on Renaissance pillars, inlaid with marqueterie or mounted in gilded bronze. The original simple shape persisted for two or three centuries—even the hood made its appearance very early. In the 18th century, however, cradles were often very elaborate—indeed in France they had begun to be so much earlier, but the richly carved and upholstered examples were used chiefly for purposes of state, being in fact miniature *lits de parade*. Later they became lighter and simpler and eventually were replaced by the barred crib.

**Craggs, James** (1657-1721), English politician, who helped promote the South Sea Bubble (*q.v.*), was born at Wyserly, Durham, on June 10, 1657. His business talents won him the patronage of the duchess of Marlborough, who obtained his election

to parliament as member for Grampond (1702-13). Craggs's connection with Marlborough established his reputation in the City of London and gave him intimate access to the speculative opportunities created by rapid developments in public finance. He held various posts in military administration until 1714. He was reappointed clerk of the deliveries after the Hanoverian accession, and he became joint postmaster general in 1715. Characteristically Craggs received heavy bribes from the South Sea company directors; after the "Bubble" he tried to secure a settlement with the government and the Bank of England. Under examination by a parliamentary committee he broke down badly, and his sudden death on March 16, 1721, appeared to many to be a confession of guilt by suicide. Much of his vast estate was sequestered for the relief of sufferers by the collapse.

His son, **JAMES CRAGGS the younger** (1686-1721) was born at Westminster on April 9, 1686. He was member of parliament for Tregony from 1713 until his death, and was rapidly advanced after the split in the Whig party, succeeding William Pulteney as secretary of war in 1717 and Joseph Addison as secretary of state in 1718. He was suspected of being involved with his father in the South Sea scandals, but on Feb. 16, 1721, during the inquiry, died of smallpox. (W. R. Wd.)

**CRAIG, EDWARD GORDON** (1872-1966), English actor, producer, stage designer, and theoretician, profoundly influenced the development of the art of the theatre in the 20th century. The son of Edward William Godwin, an architect with a passion for the theatre, and the actress Ellen Terry (*q.v.*), he was born at Stevenage, Hertfordshire, on Jan. 16, 1872. Like his sister Edith (Ellen Terry's and Godwin's other child), he received the name "Craig," which he took as his surname. Gordon Craig began his career as an actor, in Sir Henry Irving's company at the Lyceum Theatre, London, and in several touring companies (1889-97), but abandoned acting before undertaking his first important productions: Purcell's *Dido and Aeneas* (1900) and Handel's *Acis and Galatea* (1902) for the Purcell Operatic Society, and Ibsen's *The Vikings* (1903) for Ellen Terry's company at the Imperial Theatre, London. In the sets, decor, and costumes for these productions he asserted his revolutionary theories of theatrical design (see below).

In 1904, failing to find in England the financial support necessary if he was to fulfill his artistic ambitions, Craig went into voluntary exile, accepting Count Kessler's invitation to work in Germany. While there he wrote his most famous essay, *The Art of the Theatre* (1905; republ., with articles from *The Mask*, as *On the Art of the Theatre*, 1911; 5th ed., 1957). Finally arriving in Italy, where in 1906 he created the sets for Ibsen's *Rosmersholm* for Eleonora Duse, he settled in Florence. There he invented (1907) the portable folding screens he was to use in his *Hamlet* for Stanislavski at the Moscow Arts Theatre (1912); made the copperplate engravings that bear witness to his researches into the creation of an art of movement (cf. *A Portfolio of Etchings* and its preface, "Motion," 1908); and founded and edited his international review, *The Mask* (1908-29), which helped to make his theatrical ideals widely known and in which many of his articles—notably "The Actor and the Übermarionette" (1908)—were published. There too he wrote *Towards a New Theatre* (1913), which contains 40 plates of original scenic designs; and established (1913) his School for the Art of the Theatre.

After World War I (which put an end to the school's activities), although Craig took part in some outstanding productions, designing sets and scenery for Ibsen's *The Pretenders* (Copenhagen, 1926) and the decor for *Macbeth* (New York, 1928), he turned increasingly to theatrical history (*Henry Irving*, 1930; *Ellen Terry and Her Secret Self*, 1931). His work as engraver reached its peak in the illustrations for the Cranach Press *Hamlet* (Weimar, 1929; ed. by J. Dover Wilson, 1930). Other notable postwar publications were the essays and articles collected in *The Theatre Advancing* (U.S., 1919; Eng. ed., with new preface, 1921); and *Scene* (1923, with the copperplate engravings made in 1907), in which he defined his theory of the history of stage design and expounded his ideas of a stage setting based on use of portable structural elements, and the part played by light in evoking atmosphere.

EDWARD GORDON CRAIG, 1962

In 1931 he went to live in France, and in 1948 made his home in the south, where he wrote his memoirs (*Index to the Story of My Days*, 1957). He died at Venice on July 29, 1966.

From the outset, Craig propounded an art of the theatre in which reality, instead of being reproduced by the representational methods then fashionable, would be transcended and interpreted by symbol. To him outlines, forms, colours, and lighting were a means of conveying atmosphere. He aimed to restore to the theatre the dignity of an independent art, freed from the tyranny of literature, the actor, and painted sets. For Craig, no one element in a production was predominant: all, inspired and controlled by a single artistic intelligence, should combine to

create a living, dramatic whole.

His productions and, even more, his highly stylized stage designs, his woodcuts and engravings, and his writings—a blend of thought, prophetic vision, and humour—strongly influenced the anti-Naturalist trends of the modern theatre. Moreover, his work has left its mark on the production methods, acting styles, and stage decor and lighting of the commercial theatre, as well as on those of more experimental directors; and on the related arts of mime and puppetry. His work has also had a lasting effect on theatrical aesthetics, which show Craig's influence even when they react against it.

**CRAIG, SIR THOMAS** (c. 1538–1608), Scottish jurist and poet whose treatise *Ius feudale*, intended to assimilate the laws of England and Scotland, was instead an important factor in building up the law of Scotland into a separate system. He was born about 1538, a member of the Craigintray family. He was educated at St. Andrews, where he took the B.A. degree in 1555. From St. Andrews he went to Paris to study the canon and the civil laws. He returned to Scotland about 1561 and was admitted advocate in Feb. 1563. In 1564 he was appointed justice depute by the justice general, Archibald, 5th earl of Argyll; in 1573 he was appointed sheriff depute of Edinburgh, and in 1606 procurator for the church. In 1604 he came to London on the commission regarding the union of the two kingdoms. It is said that he wished to refuse the knighthood offered to him, but he has always been styled and reputed a knight.

Craig died on Feb. 26, 1608.

See P. F. Tytler, *Life and Writings of Sir Thomas Craig* (1823); life prefixed by J. Baillie's edition of the *Ius feudale* (1732).

**CRAIGAVON, JAMES CRAIG**, 1st Viscount (1871–1940), Irish soldier and statesman who struggled to maintain the union of Ireland and Great Britain and became the first prime minister of Northern Ireland, was born at Sydenham, Belfast, on Jan. 8, 1871, son of James Craig of Craigavon, near Holywood, County Down. Educated at Merchiston college, Edinburgh, he went into business as a stockbroker, served with the Royal Irish rifles in the South African War and entered parliament in 1906, winning back for the Unionist party one of the County Down seats. In the Irish Home Rule controversy which became acute after 1910 he emerged as a leader of the Ulster Unionists and worked with Sir Edward Carson to oppose Home Rule and later to secure the exclusion of Ulster from it. He had a major responsibility for the policy of threatening to establish a separate provisional government of Ulster, for the signing of the Ulster covenant, for the

organization of an Ulster volunteer force and for the Larne gun-running.

During World War I he recruited and organized the 36th (Ulster) division. In 1916 he was treasurer of the household, in 1919 parliamentary secretary to the ministry of pensions and in 1920 financial secretary to the admiralty. When the Government of Ireland act, 1920, came into operation he became prime minister and held this office for 19 years, until his death at Glencraig County Down, on Nov. 24, 1940, securing strong Unionist majorities at every general election. His government introduced many changes and reforms, including a new education system, improved agricultural marketing schemes, a nationalized road transport system and reform of the lower courts. In 1919 he was created a baronet and in 1927 a viscount. See IRELAND, NORTH-EAST: History.

See Hugh Shearman, *Not an Inch* (1942); St. John Ervine, *Craigavon, Ulsterman* (1948). (Hu. S.)

**CRAIL**, a royal and small burgh and seaside town of Fifeshire, Scot., 10 mi. S.E. of St. Andrews by road and 2 mi. from Fife Ness, the most easterly point of the shire. Pop. (1961) 1,066. Formerly called Karel, it is said to have been a town of some note as early as the 9th century; its castle, of which there are hardly any remains, was the residence of David I and other Scottish kings. It was constituted a royal burgh by a charter of Robert Bruce in 1306 and had its privileges confirmed by Robert II in 1371, by Mary in 1553 and by Charles I in 1635. Of its priory dedicated to St. Rufus, a few ruins exist. The church, which dates from the 13th century and is dedicated to Maclrubha the patron saint of Crail, was made a collegiate church in 1517. Many of the red-roofed houses are picturesque and the public buildings include an unusual early 16th-century town hall with a Dutch tower. The chief industry is fishing, especially for crabs.

Balcomie castle, about 2 mi. to the northeast, dates from the 14th century. There Mary of Guise landed in 1538, a few days before her marriage to James V in St. Andrews cathedral. Balcomie has fine sands and a famous golf links. Six miles out from Crail is the Isle of May (q.v.).

**CRAIOVA**, a town of Rumania, the administrative centre of the Oltenia region, is situated 193 km. (120 mi.) W.S.W. of Bucharest in the Jiu river valley. Pop. (1966) 148,321. An industrial, commercial and cultural centre of western Rumania the town stands on the ruins of a Thracian fortress (Palendava) and there are Roman ruins in the neighbourhood. From the 15th century to the 18th century it was the residence of the Craiova military governors or bani. St. Dumitru church was erected in 1651 by Matei Basarab, prince of Walachia. In 1802 the town was burned by the Turks.

Craiova has machine-building, electrical equipment, agricultural machinery and food-processing enterprises. Its national theatre one of the oldest in the country, was rebuilt and modernized. There are also agronomic and technical institutes and a state symphonic orchestra. The Craiova museum contains an art gallery and historical and natural history exhibits.

**OLTENIA ADMINISTRATIVE AND ECONOMIC REGION** is situated in southwest Rumania, on the Yugoslav and Bulgarian borders. Area 20,300 sq.km. (7,838 sq.mi.). Pop. (1960 est.) 1,549,976. It is divided into 15 administrative districts. In the north of the region are the Mehedinți, Vilcea and Paring mountains while the south is largely plains. The climate is continental. Drainage is through the Olt and Jiu rivers and their tributaries. Lakes Potelu, Nedea and Rastu are in the region.

The principal agricultural products are grain, industrial crops and vegetables. Fruit and vine growing and cattle breeding are well developed. The area is rich in oil deposits and natural gas (north of Craiova). There are opencast coal mines at Rovinari and Schela and graphite is mined at Baia de Aramă. The region has steadily become more industrialized. There are important dockyards at Turnu Severin building tugboats, lighters and similar craft.

**CRAM, RALPH ADAMS** (1863–1942), U.S. architect, one of the advocates of the Gothic revival, was born on Dec. 10, 1863, at Hampton Falls, N.H. Inspired by Ruskin and Viollet-

le-Duc, he became an ardent advocate of English and French Gothic styles, on which he became an authority. In 1889 he opened an office in Boston, where he became associated with B. G. Goodhue and later with C. F. Ferguson. Together they designed St. Thomas church (New York city), Emmanuel church (Cleveland), the First Baptist church (Pittsburgh) and buildings of the United States Military academy at West Point. Cram and Ferguson were consulting architects for the Washington cathedral, and transformed the cathedral of St. John the Divine (New York city) from Romanesque to late Gothic.

Cram attempted to create an environment that would convey spiritual values as a corrective to technological civilization. He insisted that educational buildings be Gothic, and designed the graduate college (1913) and chapel (1929) at Princeton university in this style. His traditionalism occasionally asserted itself in other styles, as in the classic Second Unitarian church (Boston) and the colonial buildings of Sweet Briar college (Va.). Cram was professor of architecture at Massachusetts Institute of Technology from 1914 to 1921, and served as first chairman of the Boston city planning board from 1915 to 1922. He died on Sept. 22, 1942, in Boston.

Cram's writings include *Church Building* (1901); *The Ruined Abbeys of Great Britain* (1905); *The Gothic Quest* (1907); *The Ministry of Art* (1914); *The Substance of Gothic*, Lowell Lectures (1916); *The Nemesis of Mediocrity* (1918); *My Life in Architecture* (1936); *The End of Democracy* (1937).

See also Albert Bush-Brown, "Cram and Gropius: Traditionalism and Progressivism," *New England Quarterly*, vol. xxv (March, 1952). (A. B.-B.)

**CRAMBO**, an old rhyming game which, according to Joseph Strutt in *The Sports and Pastimes of the People of England* (1801), was played as early as the 14th century under the name of the ABC of Aristotle. Crambo, or capping the rhyme, frequently mentioned in the literature of the 17th and 18th centuries, was played by one player thinking of a word and telling the others what it rhymed with, the others not naming the actual word they guessed but its meaning. Thus one said "I know a word that rhymes with bird." A second asked "Is it ridiculous?" "No, it is not absurd." "Is it a part of speech?" "No, it is not a word." This proceeded until the right word was guessed.

In Dumb Crambo the guessers, instead of naming the word, expressed its meaning in pantomime, a rhyme being given them as a clue. See also BOUTS-RIMES.

**CRAMER, JOHANN BAPTIST** (1771–1858), pianist, composer and founder (1824) of the London music publishing firm Cramer & Co., was born at Mannheim, Ger., Feb. 24, 1771, and was taken to England the following year by his father, a celebrated violinist. His piano teachers included Muzio Clementi, under whom he developed the exceptional abilities that gained him a European reputation as a performer. A prolific composer, he is remembered exclusively for his pianoforte studies, which, like his playing, were highly regarded by Beethoven. Cramer died in London, April 16, 1858. (H. Ru.)

**CRAMP**, a painful, involuntary spasmodic contraction of muscle, commonest in the limbs, but also affecting certain internal organs. Cramping is the common denominator in a variety of medical entities. Examples include menstrual cramps and spasms of the circular muscles of the bowel (irritable colon), blood vessels (vasospasm) and pylorus of the stomach (pylorospasm).

Cramps of the muscles of the extremities may occur under a variety of circumstances. Overexertion is responsible for swimmer's cramp, and the ensuing disability may lead to drowning unless the individual is rescued immediately. The violent activity of a football, basketball or hockey player may produce a cramp that stops the athlete in his tracks.

Severe cramp in the calf of a leg often awakens many persons from a sound sleep. The origin may be overstretching or strain of the affected muscle on the previous day or poor circulation, especially in the older individual. Drugs that lessen muscle irritability usually bring relief. Persons with hardening of the leg arteries also develop cramp in the calf of one leg after walking a

short distance (intermittent claudication). Pain subsides after a few moments of rest but returns after walking an equal distance. In such instances, the muscle receives enough blood when resting but cramps when it does not receive its quota during exercise.

Heat cramps involving the muscles of the extremities or abdomen stem from loss of salt following periods of profuse perspiration. Overexertion in a hot environment usually is responsible. Alkalosis also increases the excitability of nerves and muscles, leading to tetany—a severe form of cramping that is noticed first in the muscles of the extremities.

There are many neurological, reflex and psychic causes for muscle cramps. The condition is particularly bothersome in victims of multiple sclerosis and Parkinsonism.

Professional or occupational cramp is a functional spasm affecting certain muscles that are used constantly in the daily occupation. Cramping does not occur when the same muscles are employed in activities of a different kind. At first there is a gradually increasing difficulty, or clumsiness, in making the movements required for the work at hand. Writers, for example, cannot move the pen or pencil with freedom and the typist loses her dexterity in finding the right key. The telegraph operator, painter, pianist and seamstress also are candidates for occupational cramp. The first requisite of treatment is cessation of the employment that produced it. Thereafter, all causes of anxiety, overconcern and ill health are investigated thoroughly. (T. R. V. D.)

**CRANACH, LUCAS** (1472–1553), one of the leading German painters of the Renaissance, derives his name from Kronach, in upper Franconia, where he was born on Oct. 4, 1472, and where, after training in the studio of his father, Hans, he apparently remained until about 1498. In 1503, and probably for several years before, he was in Vienna, but by the spring of 1505 he had

BY COURTESY OF THE ART INSTITUTE, CHICAGO; JOSEPH BROOKS FAIR COLLECTION  
"SAINT CHRISTOPHER," A WOODCUT BY LUCAS CRANACH, 1506 (THE "S" IS REVERSED ON THE WOODCUT). IN THE ART INSTITUTE, CHICAGO

settled in Wittenberg as court painter to the electors of Saxony, a position he held until his death at Weimar on Oct. 16, 1553. Apart from a visit to the Netherlands in 1508, Cranach resided almost continuously at Wittenberg. He was a prominent citizen, a member of the town council in 1519 and burgomaster in 1537 and 1540. He was intimate with Martin Luther and with the electoral family and, apart from his other duties as court artist, he was the chief pictorial propagandist of the Protestant cause in Germany, multiplying the images of the reformers and the Protestant princes in innumerable painted, engraved and woodcut portraits. The scope of this activity is indicated by a single payment in the electoral accounts (1533) for "sixty pairs of small paintings of the late Electors." It was not without reason that Cranach's tombstone celebrated him as *pictor celerrimus*—swiftest of painters!

Hundreds of pictures now in museums and private collections, many of them dated and signed with the device of the winged serpent, which he adopted in 1508, testify to his exceptional productivity. His style was fully formed and underwent little development after about 1515, and it was faithfully imitated by a well-drilled group of studio assistants. The highly finished, mass-produced paintings of this later period suffer by comparison with the more individual work of his early manhood. His earliest known pictures, all probably executed in Vienna, show him as an avant-garde artist of considerable emotional force, one of the initiators of the Danube school. Notable among them are a "Crucifixion" (c. 1500) and "St. Jerome" (1502) in Vienna; a "Crucifixion" (1503) in Munich; portraits of "Dr. Cuspinian and His Wife" (1502-03; Reinhart collection, Winterthur) and of "Dr. Reuss and His Wife" (1503; Nuremberg, Berlin); and a "Flight Into Egypt" (1504; Berlin). In these paintings the incidents of sacred story and the accidents of human appearance merge with a wildly luxuriant landscape into a painterly vision at once pathetic and lyrical. Here, and still more in his earliest designs for woodcuts, he challenges comparison with Albrecht Dürer.

The first decade of Cranach's stay at Wittenberg was marked by a series of experiments in which he adapted his style to suit the demands of the Saxon court. The "Martyrdom of St. Catherine" (1506; Dresden) already shows a radical break with his earlier manner; there is exquisite detail in the realistic portrait heads, but courtly decorum has purged the scene of all emotion and given it a decorative bias, with strong emphasis on the patterns of dress. Following his visit to the Netherlands in 1508, Cranach experimented with Italo-Netherlandish ideas of spatial construction (Frankfurt altar, 1509) and monumental nudes ("Venus" woodcut, 1509; painted version, 1509; Leningrad). But his true bent lay elsewhere, as is shown by the splendid full-length portraits of "Duke Heinrich and Duchess Katharina of Saxony" (1514; Dresden) which mark the establishment of his official portrait style. Here space and volume are annihilated; magnificent clothes, set off by a featureless backdrop, are topped by faces reduced to their essential, typical features. Cranach was a pioneer of the frigid state portraiture of the 16th century, but he fell short of the icy reserve of his successors—Holbein, Bronzino or Mor—because his abiding Gothic taste invariably led him to exaggerate a feature or elaborate a beard or dress for the sake of linear rhythms or calligraphic effects. With male sitters his method sometimes yields an image of startling power; e.g., "Dr. Schoner" (1529; Brussels). His female portraits are uniformly vapid.

The resurgence of Gothic linear rhythms is fundamental for the whole of Cranach's later work. His "River Nymph" (1518; Leipzig) demonstrates the assurance with which he now translated a Renaissance model—Giorgione's "Venus" (c. 1510; Dresden)—into his personal language of linear arabesque. It inaugurated a long series of paintings, of Venus, Lucretia, the Graces, the Judgment of Paris and numerous other subjects serving as pretexts for the female nude, in which Cranach appears as a kind of 16th-century Boucher. The naïve elegance of these ladies and their sinuous lines, defying every principle of anatomy, were clearly to the taste of the German courts and have an enduring charm. But in conception and style they look back to the international Gothic painting of a century before.

Thus from the historical viewpoint Cranach's work was a backwater in European art of the 16th century. Though during his lifetime he was the dominant figure in the painting of northeastern Germany, his influence was confined to his immediate circle. Both his sons were members of the studio. The elder, HANS CRANACH, who died in Bologna in 1537, has left two signed works, indistinguishable in style from those of his father. LUCAS CRANACH THE YOUNGER (1515-86), whose part in the joint production of the studio became important from about 1545, continued to work in the family style and to use the family trade-mark of the winged serpent long after his father's death.

**CRANBERRY**, the fruit of several small creeping or trailing woody plants allied to the blueberries. The small-fruited or northern cranberry (*Vaccinium oxycoccos*) is found in marshy land in northern North America, northern Asia and northern and central Europe. Its stems are wiry and creeping; the leaves are evergreen, oval or elliptical in shape and less than half an inch long; the flowers, which appear in June, are small and have a four-lobed, rose-tinted corolla; the berries ripen in September, are mostly round, about the size of currants, crimson in colour and often spotted, with an acid taste.

The American cranberry (*V. macrocarpon*) is found wild from Newfoundland to the Carolinas and westward to Minnesota and Arkansas. It is much like *V. oxycoccos*, but is more robust with larger, round, oblong or pear-shaped berries that vary from pink to very dark red or may be mottled red and white. It is cultivated on acid soils of peat or vegetable mold, free from loam and clay, cleared of turf and with a surface layer of sand. Additional sand is applied to the surface every few years. It is grown extensively in Massachusetts, New Jersey and Wisconsin and near the coast in Washington and Oregon. Early Black and Howes are the main varieties in the east, McFarlin and Searls in Wisconsin and McFarlin in the far west. Three new varieties are Beckwith, Stevens and Wilcox.

False blossom is a very harmful, though easily controlled, virus disease in Massachusetts and New Jersey. Fruit-rot control is especially important in New Jersey. There are many injurious insects. Weed control by chemicals, mowing and hand weeding are important. The vines are protected from winter injury and from frosts by flooding. The picking of the berries begins early in September and continues until late October.

More than 3,000,000 bu. are ordinarily produced annually. They are used mostly as a sauce and as a relish for meats but are also much used in pies and in making a fresh fruit beverage; most of the consumption is in the United States and Canada. More than half the U.S. crop is made into a canned sauce.

The cowberry or foxberry (*V. vitis-idaea*), called mountain or rock cranberry in the eastern United States, and by some lingonberry, is not cultivated but is used extensively in northern Europe and by Scandinavians in U.S. cities. The so-called southern cranberry or red huckleberry (*V. erythrocarpum*) is indigenous in the mountains from West Virginia to Georgia and is remarkable for the fine flavour of its dark-red berry. The fruit of the cranberry tree or highbush cranberry (*Viburnum trilobum*) is sometimes used as a substitute for true cranberries in Canada and the northern United States.

**CRANBROOK, GATHORNE GATHORNE-HARDY,** 1st EARL OF (1814–1906), British statesman, a member of successive Conservative ministries, was born at Bradford on Oct. 1, 1814. He graduated from Oriel college, Oxford (1836), and was called to the bar (1840), practising on the northern circuit with slight success. He became M.P. for Leominster in 1856 and soon made his mark as a ready debater and a stern upholder of the Conservative party. He was undersecretary at the home office from 1858 to 1859 and in 1865, after a sharp contest, he won a seat for Oxford university from Gladstone. He entered Lord Derby's cabinet as president of the poor law board (1866) and succeeded Spencer Walpole as home secretary (1867). In the early 1870s he often acted as Disraeli's deputy in the commons and was war secretary in the cabinet of 1874, gaining the full confidence of the queen. He loyally supported Sir Stafford Northcote when the latter succeeded Disraeli as leader of the commons in 1876, and two years later he retired to the lords as Viscount Cranbrook of Hemsted, in Kent (May 1878), a year after having exchanged the war office for the India office.

Throughout the near eastern crisis of the late 1870s (see ENGLISH HISTORY: *The Victorian Age, 1837–1901*) Lord Cranbrook strongly supported Disraeli, who once described him to the queen as the leader in the cabinet of "the war party pure and simple." In Lord Salisbury's governments of 1885 and 1886–92 Lord Cranbrook was president of the council, and on retiring from public life when the ministry resigned in 1892 he was raised to an earldom. He lived on, amid a large family, to the age of 92, and died at Hemsted Park on Oct. 30, 1906.

See A. E. Gathorne-Hardy (ed.), *Gathorne Hardy, 1st Earl of Cranbrook* (1910).

(M. R. D. F.)

**CRANDALL, PRUDENCE** (1803–1890), U.S. school-teacher whose efforts to educate Negro girls aroused controversy in the 1830s, was born of Quaker parentage at Hopkinton, R.I., Sept. 3, 1803. She was educated in the Friends' school at Providence, taught at Plainfield, Conn., and in 1831 established a private academy for girls at Canterbury, Conn. Although the school was recognized as one of the best in the state, by admitting a Negro girl she lost her white patrons, and in March 1833, on the advice of William Lloyd Garrison and Samuel J. May, she opened a school for "young ladies and little misses of colour." For this she was persecuted, boycotted and socially ostracized; measures were taken in the Canterbury town meeting to break up the school, and finally in May 1833 the state legislature passed the notorious Connecticut "Black law," prohibiting the establishment of schools for nonresident Negroes in any city or township of Connecticut without the consent of the local authorities. Miss Crandall, refusing to submit, was arrested, tried and convicted in the lower courts, whose verdict, however, was reversed on a technicality by the court of appeals in July 1834. Thereupon the local opposition to her redoubled, and she was finally in Sept. 1834 forced to close her school. She married the Rev. Calvin Philleo, a Baptist clergyman, in 1834, and the couple moved to Illinois. After her husband's death she lived with her brother in Kansas, dying at Elk Falls on Jan. 28, 1890. The Connecticut "Black laws" were repealed in 1838. The episode of Miss Crandall's school is significant as showing the attitude of a New England community toward the Negro at that time, and throws light on the social background of the abolition movement (q.v.) in the U.S.

**CRANE, (HAROLD) HART** (1899–1932), U.S. poet who achieved renown by rhapsodically fusing American life, themes and spiritual aspirations in poetry distinguished for its experimentation and technical mastery. Born at Garrettsville, O., July 21, 1899, he had a turbulent and unhappy youth disturbed also by the industrialization of the agrarian middle west. *White Buildings* (1926), his first book, stressed his probings into the nuances of emotion. Then, unlike many contemporaries, Crane turned away from despair toward mystical affirmation. Although still reluctant to accept all phases of American life, he derived fresh impetus from Walt Whitman's faith in America's democratic future. Finally, with religious passion whose fervour was awesome, he undertook to reveal the spiritual essence of America's destiny in a series of poems unified by that great symbol of American

engineering and art, the Brooklyn bridge. *The Bridge* (1930), shadowed by Crane's recurrent doubts, was not entirely successful. Nonetheless, it confirmed his poetic powers and won him critical honours. His life, however, had been disintegrating under the pressures of personal and economic insecurity. Returning from Mexico, where he had gone to write an epic dealing with Cortés and Montezuma, Crane jumped or fell overboard into the Caribbean sea and was drowned April 27, 1932. Important in the literary renaissance of the 1920s, Crane profoundly influenced modern literature.

(B. W.; X.)

Crane's *Collected Poems*, ed. by Waldo Frank, appeared in 1933, and his *Letters, 1910–1912*, ed. by Brom Weber, in 1952. See also Philip Horton, *Hart Crane* (1937); Brom Weber, *Hart Crane* (1948); and H. D. Rowe, *Hart Crane, a Bibliography* (1955).

**CRANE, STEPHEN** (1871–1900), U.S. author, won outstanding fame as novelist, poet and short-story writer. Born Nov. 1, 1871, in Newark, N.J., Crane was still a brilliant prodigy when he died of tuberculosis in Germany at the age of 29. As William Dean Howells said, Crane's genius seemed to "spring to life fully armed." The sources of his vivid style and individual vision of life are still somewhat mysterious. His father, Jonathan Crane, an intellectually inclined Methodist minister of good family, died in 1880, leaving Stephen, the last of 14 children, to be reared by his devout, strong-minded mother. After preparatory school at the Claverack college or Hudson River Military institute, Crane spent one baseball-minded semester at Lafayette college and another at Syracuse university in 1890–91 and then went to New York to live in a medical students' boardinghouse while freelancing his way to a literary career. Alternating Bohemian student life and exploration of the Bowery slums with genteel visits to relatives in the country near Port Jervis, N.Y., Crane gathered his forces for his first book, *Maggie: A Girl of the Streets* (1893), a sympathetic study of the bitter warfare of life in the slums.

At that time so shocking that Crane published it under a pseudonym and at his own expense, *Maggie* left him to struggle as a free-lance journalist, poor and unknown until he was befriended by Hamlin Garland and Howells. Suddenly in 1895 *The Red Badge of Courage* and his first book of poems, *The Black Riders*, brought him dazzling international fame. Strikingly different in tone and technique from *Maggie*, *The Red Badge of Courage* reaffirms Crane's view of life as warfare, and studies a young person trying to find reality amid conflict. His hero, Henry Fleming, survives fear, cowardice, illusion and vainglory and so discovers courage, humility, and perhaps wisdom in the confusion of an unnamed Civil War battle. Crane, who had as yet seen no war, was widely praised by veterans for his uncanny power to imagine and reproduce the sense of actual combat.

Crane's few remaining years were chaotic and personally disastrous. His unconventionality and sympathy for the downtrodden were distorted by malicious gossip into false charges of drug addiction and Satanism which disgusted the fastidious Crane. His reputation as a war writer, his desire to see if he had guessed right about the psychology of combat, and his fascination with death and danger sent him to Greece and then to Cuba as a war correspondent. After his marriage in 1897 he made his headquarters in England until just before his death. There he won the friendships of two other American expatriates, Henry James and Harold Frederic, as well as Joseph Conrad. Privation and exposure in his Bowery years and as a correspondent, together with an almost deliberate disregard for his health, probably hastened if they did not bring on the disease which killed him so young.

After *The Red Badge of Courage*, Crane's few attempts at the novel were of small importance, but he achieved extraordinary mastery of the short story. He exploited youthful small-town experiences, *The Monster and Other Stories* (1899) and *Whilomville Stories* (1900); the Bowery again, *George's Mother* (1896); an early trip to the southwest and Mexico, "The Blue Hotel," "The Bride Comes to Yellow Sky"; the Civil War again, *The Little Regiment* (1896), and war correspondent experiences, *The Open Boat and Other Tales of Adventure* (1898) and *Wounds in the Rain* (1900). In the best of these tales Crane showed rare ability to shape colourful settings, dramatic action and perceptive char-

acterization into ironic explorations of human nature and destiny. In even briefer scope, rhymeless, cadenced and "free" in form, his unique, flashing poetry was extended into *War Is Kind* (1899). Dramatic, symbolic, ironic in method, astringent in atmosphere and sound, Crane's poetry has often been accounted one of the earliest effective revolts against 19th-century Tennysonian verse and the next important step after Emily Dickinson toward modern poetry.

Crane's literary generation was a tragic one, also losing Frank Norris and Harold Frederic prematurely from its ranks. Yet had the generation produced nothing more than the unique work of Stephen Crane, it would be secure in the major position he has won in the history of American literature.

There is an edition of Crane's work in 12 volumes, edited by Wilson Follett (1925-26), which, however, omits some work of interest. Follett also edited *Collected Poems of Stephen Crane* (1930). R. W. Stallman's *Stephen Crane: An Omnibus* (1952) includes novels, short stories, poems, newspaper articles and letters, with critical notes and introductions. *Stephen Crane's Love Letters to Nellie Crouse, with Six Other Letters* was edited by Edwin H. Cady and Lester G. Well (1954).

**CRANE, WALTER** (1845-1915), English illustrator and painter, known for his imaginative illustrations of children's books, was the second son of the portrait painter and miniaturist Thomas Crane (1808-59) and was born in Liverpool on Aug. 15, 1845. Having moved to London, Crane became an apprentice to the wood engraver W. J. Linton, 1859-62, and thus was able to study both the Italian old masters and contemporary work by D. G. Rossetti, Sir John Millais, Sir John Tenniel and Frederick Sandys. Probably the most important technical development in his art derived from the study of Japanese colour prints, whose methods he used in a series of toy books (1869-75), thereby starting a new fashion. The ideas and teachings of the Pre-Raphaelites and of John Ruskin manifested themselves in his early paintings such as "The Lady of Shalott" (Royal Academy, 1862). The Academy steadily refused his later work, but the opening of the Grosvenor gallery in 1877 enabled him regularly to show there until 1888. He became an associate of the Royal Water-colour society in 1889 and a member in 1902. In 1864 he began to illustrate for Edmund Evans, the colour printer, an admirable series of sixpenny toy books of nursery rhymes. A new series, beginning with *The Frog Prince* (1873), was more elaborate, and to the Japanese influence was added that of Florentine 15th-century painting, following upon a long visit to Italy.

A strong didactic, moral element underlies much of his work, and for several years Crane contributed weekly cartoons for the socialist periodicals *Justice* and *The Commonwealth*, many of which were collected as *Cartoons for the Cause* (1896). He was founder-president of the Art Workers' guild, and in 1888 founded the Arts and Crafts Exhibition society. As a teacher he exerted wide influence, becoming art director first of the Manchester School of Art (1893-96), then of Reading college (1896-98) and finally principal of the Royal College of Art, South Kensington (1898-99). His chief importance lies in book illustration, the standard of which he helped greatly to raise. He worked with William Morris in 1894 on the page decorations of *The Story of the Glittering Plain*, printed by the Kelmscott press in the style of 16th-century German and Italian woodcuts. Among the best of his book illustrations are those for Edmund Spenser's *The Faerie Queene* (1894-96) and *The Shepherd's Calendar*. He died at Horsham, Sussex, on March 14, 1915.

**CRANE**, any of 14 species of tall wading birds of the family Gruidae, placed with rails (*q.v.*) in the order Gruiformes. They are commonly confused with herons (*q.v.*), which they resemble superficially, but are usually larger and have a part-naked head,

ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

WHOOPIING CRANE (*GRUS AMERICANA*)

4 by 2½ in., are laid in a nest of grasses and weed stalks on drier ground in marsh or field; the same nest may be used year after year. The brownish, downy young can run about shortly after hatching. The trachea or windpipe is simple in the chick ready to leave the egg; with advancing age the trachea lengthens, coiling upon itself, like a French horn. The trachea lies buried in the hollow keel of the breastbone and reaches a length of five feet in the whooping crane (*Grus americana*), noted for its peculiar loud whooplike call.

The whooping crane, on the verge of extinction, is the tallest of American birds. It is white with black primaries, measures about 52 in. long (wingspread 92 in.) and breeds in southern Mackenzie district and northern Saskatchewan, wintering in southeastern Texas. The little brown crane (*G. canadensis canadensis*), 35 in. long, breeds from Alaska to Hudson bay, wintering from California and Texas south into Mexico. The sand-hill crane (*G. c. tabida*), 44 in. long and chiefly brownish-gray in colour, formerly bred in southern Canada and the northern half of the U.S., is now rare east of the Mississippi. Its call is long, harsh, penetrating. The Florida crane (*G. c. pratensis*) breeds in Florida (Okefinokee swamp), southern Georgia and probably Louisiana. The common crane (*G. grus*) breeds in Europe and northern Asia, formerly in England, migrating southward in large flocks in autumn to winter in northern Africa, India and China. The native companion (*G. rubicunda*) lives in Australia and southern New Guinea. The demoiselle crane (*Anthropoides virgo*) breeds in Algeria, southeastern Europe and central Asia; the crowned crane (*Bucconia pavonina*), over nearly all of Africa; and the wattled crane (*Bucconia carunculatus*), in eastern and southern Africa. (G. F. Sa.)

**CRANE**, a machine by means of which heavy bodies may be lifted and also be displaced horizontally, within certain defined limits, and which is so called from its resemblance to the long neck of the bird of this name. Strictly speaking, the name alludes to the arm or jib from which the load to be moved is suspended, but it is now used in a wider sense to include the whole mechanism by which a load is raised vertically and moved horizontally. Machines used for lifting only are not called cranes, but winches, lifts or hoists, while the term elevator or conveyor is commonly given to appliances which continuously, not in separate loads, move materials like grain or coal in a vertical, horizontal or inclined direction (see MATERIAL HANDLING). The use of cranes is of great antiquity, but it is only since the great industrial development of the 19th century and the introduction of motive powers other than hand labour that the crane has acquired the indispensable position it now occupies. In all places where finished goods are handled or manufactured goods are made, cranes of various forms are in universal use.

#### CLASSIFICATION OF MOTIVE POWER

**Crane Movements and Stability.**—Cranes may be divided

heavier bill, more compact plumage and elevated hind toe. In flight the long neck is stretched out in front, the stiltlike legs trailing out behind.

Cranes form an ancient group, the earliest fossils having been recovered from the Eocene of North America; the fossils *Gruonoides* and *Eogrus* are placed in separate families in the superfamily Gruoidea. Living forms inhabit all the great zoogeographical regions except the neotropical (South America).

These graceful terrestrial birds stalk about in marshes and on plains, eating small animals of all sorts as well as grain and grass shoots. Two olive-gray eggs, spotted with brown and measuring

**Diesel Power.**—It is becoming increasingly usual to drive by diesel-powered cranes that are required to be self-contained, especially rail-mounted and mobile cranes. These can be driven directly from the diesel engine with the use of a suitable clutch

FIG. 2.—(A) OVERHEAD ELECTRIC TRAVELING CRANE; (B) OVERHEAD TRAVELING CRANE WITH UNDERSLUNG CAB AND BOOM

A variation of the overhead crane is shown in fig. 2(B). This, instead of being fitted with a plain trolley and hook, incorporates an underslung jib. The advantage of this type of crane is apparent from the illustration, which shows that it can handle loads outside the span of its supporting gantries.

It is not always practicable to erect a gantry for an overhead crane. In this case a goliath crane is used. With this type of crane the runway track is at ground level and is designed to cause the least possible interference at this level in the area where the crane operates. Goliath cranes with lifting capacities as great as 300 tons have been built, and they are sometimes used for building power stations, as this necessitates the handling of heavy loads in the open. In such a case the cranes are occasionally dismantled and removed after construction is completed.

The duties of cranes of the overhead and goliath types vary considerably. Sometimes a heavy crane, though necessary, may be used only occasionally for maintenance purposes; on the other hand it may be worked on a continuous day and night duty cycle. The steelworks ladle crane is an example of the latter use. This type of crane can be designed for loads of 300 tons or more. Also used in steelworks are special steelworks charging cranes, a typical example of which is shown in fig. 3. This type of crane is specially designed not only to stand up to the continuous and arduous duty in a steelworks but also to withstand the heat and dust prevalent in a foundry and, in addition, to be speedily maintained.

**Scotch Derricks.**—There is always a need for cranes which are portable and which can be used on building sites. Typical of cranes for this work is the scotch derrick shown in fig. 4. A scotch derrick is usually designed for electrical operation and for lifting loads of up to 30 tons. Such cranes are generally fitted with long jibs of 100–120 ft., and, to obtain extra height of lift, they are sometimes mounted on structural trestles. The principal characteristics of this type of crane are exceptional height of lift and ease of erection and dismantling for transfer from site to site.

**Dockside Cranes.**—For the rapid loading and discharging of

ships' cargo, the most popular type of crane is the level-luffing traveling dockside crane. These cranes are nearly always electrically driven, although occasionally the luffing, or change of altitude, of the jib is obtained by hydraulic means. Dockside cranes are manufactured principally with lifting capacities ranging from 3 to 10 tons, although cranes of this type have been designed for lifting 15 and 20 tons. A typical dockside crane of 3 tons capacity would have a hoisting speed of 240 ft. per minute, a traveling speed of 100 ft. per minute, a slewing speed of  $1\frac{1}{2}$  r.p.m., and a luffing speed of 150 ft. per minute. It is often necessary, for the purpose of avoiding obstructions, to design the crane for mounting partly on the quay and partly on a gantry at a higher level. Such an arrangement is described as a semi-portal crane. A full portal crane is employed where the crane carriage has to span railroad tracks, so that the trucks may pass beneath.

Besides handling general merchandise, dockside cranes are frequently required to discharge bulk cargo, such as iron ore, phosphates, coal, etc., when they must use grabs. These are hook on, self-dumping, ring discharge or

multirope. For a dockside crane used mainly for grabbing duty the multirope type grab is preferred.

A variety of crane specially developed for the bulk discharge of materials is the kangaroo crane (see fig. 5). In this case the material is deposited in a hopper in front of the gantry, from where it passes through a weighing machine onto a belt conveyor, which discharges it through the rear of the gantry onto another conveyor.

Most dockside cranes are designed for level luffing, which means that the load is neither lifted nor lowered when the jib is luffed in or out. This feature has been found to be indispensable for rapid cargo-handling operations, and many designs have been developed to achieve it. In one, the jib is of the balanced type and is fitted with a lever arm at its head, the relative movement of which at varying radii of the crane and with a normal rope reeving, achieves the level luffing of the load. In another type, the jib is likewise balanced but is luffed by a rack and pinion. A special rope reeving is arranged in three parts between the jib head and the apex frame to provide level luffing. This arrangement is employed in the kangaroo type of crane shown in fig. 5, but the jib is crank operated for luffing.

A further system of level luffing incorporates a parallelogram jib arrangement which, together with a normal rope reeving, gives level luffing of the load.

**Shipyards Cranes.**—For the construction and fitting-out of ships in shipyards, various types of special cranes have been developed. The heavy lifts in shipbuilding usually occur when the main machinery is being installed, and for this purpose fitting-out berths are generally equipped with one heavy crane, usually of the fixed cantilever type. Such cranes have been manufactured with a lifting capacity of about 250 tons. One example lifts this load at a radius of 115 ft., the height to the rotating portion being 133 ft. The speed of hoisting 250 tons is 6 ft. per minute, and the

trolley has a traversing speed of 30 ft. per minute with the full load. The crane is capable of slewing through one revolution in about seven minutes when loaded. This type of crane is found in naval dockyards.

For shipbuilding berths, cranes of the tower or monotor type are usually employed (see fig. 6). As many as six of these cranes are often installed adjacent to a

shipbuilding berth. Their lifting capacity is usually between 15 and 50 tons.

Dry docks are equipped with heavy cranes for moving propellers, machinery, etc., from ships during refitting. The usual type of crane employed is shown in fig. 7. In this design the luffing of the jib is effected by the use of wire ropes, and in the crane shown in fig. 8 the jib is operated by special screws. This type of dry-dock crane has a lifting capacity of 30–50 tons.

Both shipyard and fitting-out cranes are often required to place loads accurately, and this necessitates extremely fine electrical control for the hoisting and lowering motions. This can be achieved by using A.C. commutator motors or Ward-Leonard electric drive. There is an increasing preference for the level-luffing feature to be incorporated in this type of crane.

**Transporter Cranes.**—The handling of bulk cargo by means of grabbing cranes has been mentioned and particular reference made to the kangaroo, which lifts the load and luffs it over its own hopper, no slewing being involved. When the handling of bulk cargo is undertaken on a large scale, however, preference is given to the transporter cranes. These are made in three designs: the first unloads (see fig. 9), the second reclaims and the third does

**CRANMER, THOMAS** (1489-1556), the first archbishop of Canterbury of the reformed Church of England and a martyr in the reign of Queen Mary I, was born at Aslacton, Nottinghamshire, on July 2, 1489, the second son of Thomas Cranmer and Agnes, née Hatfield. His father seems to have belonged to the lowest rank of the gentry; at any rate, he had only enough property to endow his eldest son, John, while Thomas and his younger brother, Edmund, were destined for the church. After experiencing the teaching of a "marvellous severe and cruel schoolmaster," whose ministrations Cranmer later maintained instilled in him a permanent uncertainty and pliability, the boy went on to Cambridge (1503). It is not known to which college he belonged as an undergraduate, but by 1510 or 1511 he had been elected into a fellowship at Jesus college. This he was soon compelled to vacate because he married a certain Joan, a relative to the landlady of the Dolphin inn. During this time he kept himself by teaching for Buckingham (later Magdalene) college and left his wife to lodge at the Dolphin; out of this arrangement grew the later story that he had started life as an ostler. Joan, however, died in childbirth a year after their marriage, and Jesus college restored Cranmer to his fellowship. He now entered the church and threw himself into his studies, becoming one of the outstanding theologians of his time, a man of immense though not very original learning. From about 1520 he formed one of a group of scholars who met regularly at the White Horse inn to discuss the theological and ecclesiastical problems raised by Luther's revolt; known to be inclined to the new way of thinking, they were dubbed "Little Germany." Here gathered some who were to lead the first gen-

eration of the English Reformation—William Tyndale, Robert Barnes, John Frith, Thomas Bilney and, above all, Cranmer, who by 1525 included among his prayers one for the abolition of papal power in England.

**Entry Into Royal Service.**—However, these ambitions would have remained as academic as their author but for the political events into which Cranmer was soon drawn, much contrary to his upbringing and tastes. From 1527 onward, Henry VIII pursued his desire to be freed from his first wife, and in 1529 the wheels of the "divorce" seized also upon Cranmer. An accidental meeting with two of the king's councilors (Stephen Gardiner and Edward Foxe, both old Cambridge men), at which Cranmer is alleged to have suggested that the king might strengthen his case by seeking the opinions of the European universities, brought the middle-aged scholar to an interview with Henry. Cranmer accepted a commission to write a propaganda treatise in the king's interest, was (probably) appointed archdeacon of Taunton and suddenly found himself, like so many others, in the royal service. It was a fateful moment, from which stemmed the whole remaining history of his life. Soon he was employed in a variety of duties, defending the king's position before the English universities, serving as a minor member of one of the many embassies sent to Rome (1530) and as the leading member of one sent to Germany (1532), officially to the emperor but with instructions to establish contact with the Lutheran princes. At Nürnberg he made the acquaintance of Andreas Osiander whose theological position midway between Luther and the old orthodoxy appealed to Cranmer's cautious temperament, while his niece Margaret appealed even more strongly to the instincts of one who had for too long remained in uncongenial celibacy. Despite his priest's orders he married her in 1532; at the same time, his theological views underwent a further decided change in the direction of reformed opinion.

**Archbishop of Canterbury.**—In fact, the year 1532 proved to be a critical one altogether, for in August William Warham, the aged archbishop of Canterbury, died. At first the usual practice was followed of extending the vacancy for the benefit of the king's finances, but by the end of the year it was apparent that the see would have to be filled because the divorce question was coming to a head. Thomas Cromwell's arrival in power had heralded a more energetic policy; by Jan. 1533 the act against appeals to Rome, intended as the gage of battle, was being drafted and Anne Boleyn was pregnant. Since Gardiner, the obvious candidate for the archbishopric, was out of favour, the king chose Cranmer; by March 1533 he was consecrated and instituted at Canterbury, with the assistance of confirmatory papal bulls and after a declaration that he took the obligatory oath to the pope without feeling bound by it. He proceeded to do what was expected of him. In May he convened his court at Dunstable (Bedfordshire), declared the king's marriage to Catherine of Aragon void from the beginning and pronounced the second marriage to Anne Boleyn valid. In 1536, convinced by the dubious evidence of Anne's alleged adulteries, he in turn invalidated that marriage; in 1540 he assisted at the freeing of Henry VIII from Anne of Cleves; and in 1542 he was forced to be prominent in the proceedings which resulted in Catherine Howard's execution for treasonable unchastity. There is no question that in these matrimonial politics he did as he was told, though it is entirely improbable that his private opinions on the issues in question in any way contradicted his public doings.

More significant, in any case, are his activities as archbishop in the reconstructed church. Cranmer had not sought high promotion. His marriage just before his elevation to Canterbury is fair proof that he expected no such career in the priesthood, in which a necessarily unacknowledged wife would be nothing but an embarrassment. Not until 1548 was he able publicly to recognize her, though the story of his carrying her about with him in a chest with air holes is part of the scurrilous legend which grew up around him. Once put in power, however, he could not avoid the consequences; a convinced reformer with leanings toward a succession of continental theological changes, he found himself assisting at the shaping of the Church of England under a master who on the whole had no taste for change. In co-operation with

Cromwell he promoted the publication of an English Bible, made compulsory in the parishes by Cromwell's Injunctions of 1538. Even before Henry VIII died (1547), his archbishop had drifted far in the direction of Protestantism, had composed (1545) the Litany still in use, one of his masterpieces, and (by 1538) had abandoned belief in transubstantiation though not in the real presence. As early as 1536 he was recognized by the northern rebels as the leading innovator. His position was in consequence far from comfortable after the reaction to the old ways signaled by the Act of Six Articles (1539) and Cromwell's fall (1540). During Henry's last years, Cranmer's enemies laid at least three elaborate plots to destroy him by convicting him of heresy, but on each occasion they were foiled by Henry's curious attachment to him. In Cranmer this king, who as a rule kept himself entirely free from personal feelings for his servants and advisers, found a man whom he both trusted and liked. Unlike the rest of them, the archbishop was neither greedy nor devious; he sought nothing for himself, alone was willing to plead for those who fell into disfavour a service he performed with equal courage and futility for Thomas More, Anne Boleyn, Thomas Cromwell and others) and miraculously retained Henry's good will throughout. The king regarded him with that mixture of awe and amusement which the worldly and selfish bestow on those who appear simple in affairs; he liked him, listened to him, protected him but allowed him no political influence whatsoever. Not surprisingly it was to Cranmer that he turned when death came.

**Achievements Under Edward VI.**—Cranmer's time really arrived with the accession of Edward VI in 1547. Edward Seymour, the protector Somerset, from the first demonstrated his intention to transform the Church of England into a Protestant church, and when he fell in 1549 the expected Catholic reaction did not take place because the duke of Northumberland decided to introduce an even more extreme brand of reformed religion. In the doctrinal labours demanded by these changes Cranmer took the chief and directing part. In 1547 he was responsible for the publication of a *Book of Homilies* designed to meet the notorious grievance that the unreformed clergy did not preach enough. The first prayer book, moderately Protestant, appeared in 1549, to be followed in 1552 by the second which in effect came very near the extremes of Zürich. Cranmer was personally responsible for much of the work, but he had the assistance of a number of foreign theologians for whom Edward VI's England acted as a magnet. The most influential of these was probably Martin Bucer from Strasbourg whose position on the Eucharist is reflected especially in the communion service of the second prayer book. However it was not so much Bucer who persuaded Cranmer away from the vague Lutheranism, which seems to have been his position in 1547, as either the Pole John à Lasco or the Englishman Nicholas Ridley, both men possessed of a more determined and unquestioning temper than was the archbishop. The ferment of those years also produced Cranmer's 42 Articles (1553), the basis of the later 39 and a monument to his comprehensive spirit, as well as his striking attempt to revise the canon law of the English church, never enacted but published in 1571 as the *Reformatio legum ecclesiasticarum*. Though still deprived of any serious influence in affairs of state, Cranmer dominated and guided the religious revolution of the reign by his learning, authority and unwavering diligence. He settled in turn the doctrine, ritual and law of his church in a manner which was to remain fundamental to later developments; above all, the Church of England owed to him the beauty of its liturgy which shows him to have been not only a theologian but something of a poet.

**Degradation and Martyrdom.**—Edward VI's approaching death (July 1553) at long last involved Cranmer fatally in politics. After prolonged resistance he was forced by the dying king to subscribe the document by which Northumberland hoped to upset custom, statute law and the will of Henry VIII in order to transfer the succession from the princess Mary to his daughter-in-law Lady Jane Grey. The failure of the plot brought Cranmer within the clutches of the treason law under which he was condemned by Mary's government in Nov. 1553. It had in any case become obvious before this that his future held no more bright promises.

Mary's accession temporarily destroyed the English Reformation; Cranmer's embittered enemy Stephen Gardiner was at once released from imprisonment and promoted to the chancellorship, and in Nov. 1554 Cardinal Reginald Pole arrived to occupy Canterbury and direct the extirpation of heresy. Cranmer's trial for treason was but a pretense; the queen and her advisers did not intend him to die for the technical offense of having supported Northumberland's insane conspiracy but meant to destroy him for his long-standing offense in promoting Protestantism. They had to wait until they could get parliament to repeal the acts of Henry VIII and Edward VI and to reintroduce the laws which enabled the secular arm to burn heretics. With Ridley and Hugh Latimer, Cranmer in March 1554 was removed to Oxford where the Counter-Reformation felt safer than in Cranmer's own university. Late in that year the heresy laws were revived, and in Sept. 1555, after enfeebling imprisonment, Cranmer was subjected to a long trial in which he stoutly defended himself against the charge of having unjustifiably departed from his own earlier position on the sacraments and the papacy. The foregone conclusion was arrived at after a variety of technical processes; on Feb. 14, 1556, in a ceremony full of carefully designed humiliation, he was degraded from his episcopal and sacerdotal offices and handed over to the state.

However, Mary's government had not done with him yet. The burning of the archheretic would be an even more useful deed if he could be made to renounce his errors in public, and so a number of ways were tried to break him down. In the previous October he had been made to witness the martyrdom of Ridley and Latimer; now he was temporarily removed from prison into pleasanter surroundings while government agents tried to stir up his doubts. In fact, Cranmer signed five so-called recantations of which the first four did no more than record his consistent belief that what monarch and parliament had decreed must be obeyed by all Englishmen. His convictions on this point logically forced him to accept the Marian Counter-Reformation as valid, and this in turn, in his weak and uncertain state, not unaffected by the delay of death and the faint hope of mercy, finally induced him to make an abject recantation (the sixth) of his whole religious development. The government had every reason to hope that the publication of Cranmer's defection would wreck Protestantism in England. No mercy was to be extended to the old man; though the vengeful Gardiner had died, Mary and Pole were quite determined that the sentence must be carried out. Thus on March 21, 1556, Cranmer was taken out to be burned, being first required to make his recantation public. The proximity of death, however, restored both his faith and his dignity. With nothing to lose and only peace of soul to gain, he shocked his enemies by disavowing his recantation and emphatically reasserting that the pope's power was usurped and transubstantiation untrue. At one blow he undid all that government propaganda had achieved and restored heart to the surviving reformers. Then he went to his death. As he had promised, he steadfastly held his right hand—which "had offended" by signing the false recantations—into the flame until it was consumed, and soon afterward the fire killed him. His brave and dignified end made an enormous impression.

**Character and Opinions.**—Cranmer was a very human man who in consequence has attracted a good deal of obloquy from those who have not had to share his tribulations and temptations. Essentially he was and remained a scholar who lacked the strength which single-mindedness and fanaticism instill into the less reflective. He has sometimes been thought of as infirm in moral purpose, but this is to misjudge him. His doubts at the last were cleverly induced by mental torture, and his gradual development away from traditional orthodoxy into more and more definitely Protestant views represents fairly the spiritual career of a man who obeyed reason rather than instinct. Cranmer was always learning and never ashamed to admit it; his was essentially a humble temper. He had not sought high office and did not enjoy it much, though he valued his place for the chance it gave him to promote the changes which he came to regard as essential to the establishment of God's truth. He refused to bear malice or punish those who traduced him. When Cromwell once told him, in some exasperation, that the "popish knaves" would have his eyes

and cut his throat before he would do something about it, Cranmer turned the prophecy with a shrug. In a persecuting age he stood out for his clemency, though in 1550 he did take part in the trial and burning of Joan Bocher; it should be remembered that she was condemned for open blasphemy in denying the Trinity, the one offense which all the church had regarded as unforgivable ever since the struggle with Arianism. For his order and the authority of the church Cranmer had a high respect which, for instance, appears in his revision of the canon law.

However, his most consistent principle was one which was unlikely to gain him much sympathy in later ages. It was part of his religious beliefs that he owed obedience to the king; though he did not worship the state, he served it without hesitation and as a matter of principle. This did not, as is sometimes alleged, make him servile; alone of Henry VIII's councilors, he time and again spoke up for the unpopular victim of the moment, and his tart criticism of the king's theology and grammar in the debates over the King's Book of 1543 speaks well for his courage. He stood up to Northumberland when everyone else quailed before that half-demented demon. These occasional disputes only underline the fact that with him submission to royal authority was ordinarily a fundamental, indeed a doctrinal, tenet. However, though he may have been more consistent in this than most, he only stressed more heavily what nearly everybody held at the time. His other guiding star was his study of theology in which he early discarded the arid aftermath of late medieval scholasticism and turned instead to Scripture and the early Fathers. Between them, his belief in the divine right of kings to rule the *ecclesia* as well as the *res publica* and his biblical theology made him the characteristic Anglican of his day, the intellectual and in part the spiritual founder-father of that particular reformed church.

**BIBLIOGRAPHY.**—Jasper Ridley, *Thomas Cranmer* (1962), the best biography, contains a sufficient summary of the materials for Cranmer's life. C. H. Smyth, *Cranmer and the Reformation Under Edward VI* (1926), is particularly useful for the influence of foreign scholars; a recent attempt to deny their importance made by C. W. Dugmore, *The Mass and the English Reformers* (1958), has met more criticism than acceptance. For a hostile view, see P. Hughes, *The Reformation in England*, vol. i, ii (1950-53); for a more favourable one, T. M. Parker, *The English Reformation to 1558* (1950), and J. D. Mackie, *The Earlier Tudors* (1952).

**CRANNOG**, an Irish word applied in Scotland and Ireland to artificially constructed house or settlement sites built of timber, sometimes with stone structures, and situated off the edge of a lake. They range in time from the Late Bronze Age into the Middle Ages. Usually constructed on islets or shallows in the lakes, they were fortified by single or double stockaded defenses around the margin. Their distinctive substructures of brushwood and logs built up from the bottom set them apart from the pile constructions of earlier periods in Switzerland (see LAKE DWELLINGS). Implements and weapons from Irish and Scottish crannogs are usually iron; even the objects of bronze and stone are typical of those dating from the Iron Age. Crannogs are among the latest prehistoric strongholds, and seem to have reached their greatest development in early historic times. A few remains of lake-village structures that have been excavated in England and Wales suggest typical crannog structure (see GLASTONBURY). See also IRELAND: *Archaeology*.

See "Lake Dwellings, Crannogs and Terremare," in G. E. Daniel, *A Hundred Years of Archaeology* (1950). (S. Pt.; X.)

**CRANSTON**, a city of Rhode Island, U.S., is in Providence county on the west shore of Narragansett bay. Dependent for many services on Providence, which it adjoins, Cranston is primarily a residential suburb. However, industrial plants produce textiles, machinery, wire, rubber and beer. Agriculture is limited to a few dairy farms, market gardens and nurseries.

The first settlement was at Pawtuxet in 1636 by William Arnold, a compatriot of Roger Williams. Cranston separated from Providence in 1754 and was named for Samuel Cranston, governor of Rhode Island from 1698 to 1727. Its early growth was dependent on the textile industry and dates from the founding in 1824 of the Cranston Print works.

Cranston became a city in 1910. Growth has been rapid since 1940 with several large housing developments. Population in 1960

was 66,766 according to the federal census.

State institutions located on 667 ac. of land include the adult correctional institutions, the juvenile training schools, the hospital for mental diseases, the state infirmary and the county jail. Points of interest are the Friends Meeting-House (1729), the Budlong Rose Company gardens (commercial) and the pre-Revolutionary Caleb Arnold tavern. There are two yacht clubs and five recreational areas including Meshanticut park, a 42-ac. state reservation.

(V. H. WH.)

**CRANTOR** (4th–3rd century B.C.), Greek philosopher, a native of Soli in Cilicia, a pupil of Xenocrates and Polemo and the teacher of Arcesilaus, wrote the first commentary on Plato's *Timaeus*, denying that Plato actually ascribed a beginning in time to the universe and its soul. In one of his works he presented a contest in which manliness (*andreia*—equated with "virtue") wins over wealth, health and pleasure. His writing *On Grief* created a new literary genre; viz., the consolation (offered on the occasion of a misfortune such as death). One of Crantor's consolatory arguments, reminiscent of Plato's *Phaedo* or Aristotle's *Eudemus*, was that life is actually punishment, death the release of the soul. He advocated moderation of emotions rather than their suppression as demanded by Stoics. His writings are lost. See also ACADEMY, GREEK.

(PP. M.)

**CRANWORTH, ROBERT MONSEY ROLFE**, BARON (1790–1868), lord chancellor of England, was born at Cranworth, Norfolk, on Dec. 18, 1790. Educated at Bury St. Edmund's, Winchester, and Trinity College, Cambridge, he was called to the bar at Lincoln's Inn in 1816 and attached himself to the Chancery Courts. He represented Penryn and Falmouth in Parliament from 1832 till his promotion to the bench as baron of the exchequer in 1839. In 1850 he was appointed a vice-chancellor and created Baron Cranworth, and in 1852 he became lord chancellor in Aberdeen's ministry. He continued to hold the chancellorship in the administration of Palmerston until the latter's resignation in 1857. He was not reappointed when Palmerston returned to office in 1859, but on the retirement of Lord Westbury in 1865 he accepted the great seal for a second time and held it until the fall of the Russell administration in 1866. Cranworth died in London on July 26, 1868. His name is associated in the statute book with only one small measure on conveyancing. He left no issue and the barony became extinct on his death.

**CRASH**, a group of coarse, rugged fabrics made from yarns that are irregular, firm, strong and smooth but sometimes raw and unprocessed. This fabric group includes gray, bleached, boiled, plain, twill and fancy-weave crash. The coarsest type is called Russian crash. Crash is used frequently for toweling, especially the type that is 14 to 20 in. wide and is dispensed from a roller.

Linen is generally used for the warp yarn, while linen, jute or a mixture of linen and jute may be used for the filler. In the U.S., fibre content must be declared, according to a ruling of the Federal Trade commission. Crash may or may not be made with novel or fancy borders, and it is sold in white or natural shades or in dyed colours. Other uses of crash, in addition to the production of toweling, include the manufacture of draperies and other decorative cloths, doilies, dresses, caps, summer suits and sport coats.

The term is derived from the Latin *crassus*, meaning coarse.

(G. E. L.)

**CRASHAW, RICHARD** (1613?–1649), English poet famous for his ardent faith, glowing imagination and brilliant wit, was born in London c. 1613. His father, William Crashaw, a learned and zealous Puritan, was preacher to the Inner Temple and (1618–26) incumbent of St. Mary Matfellow, Whitechapel. Richard Crashaw went to the Charterhouse and, in 1631, to Pembroke college, Cambridge, whence he graduated B.A. in 1634. In that year also he published *Epigrammatum Sacrorum Liber*, a collection of Latin verses on scriptural subjects, some of which may have been written much earlier, as school exercises. In 1635 he was admitted to a fellowship at Peterhouse, a centre of Laudianism, and was soon ordained. His High Church leanings appear again in his friendship with Nicholas Ferrar's religious community at

Little Gidding, Huntingdonshire. During the Great Rebellion his position at Cambridge became difficult and he seems to have relinquished it in 1643, about a year before he was formally ejected from it by the Parliamentarians. Crashaw made his way first to Holland and then to France, and he became a Roman Catholic. When Queen Henrietta Maria and her entourage moved to Paris, Crashaw was found there by his Cambridge friend Abraham Cowley, living in great poverty; and he was then sent to Rome with a recommendation from the queen to the pope. After some delay he was appointed, in 1649, to a canonry at the cathedral of the Santa Casa at Loreto; but his tenure was short for he was taken ill and died there on Aug. 21, 1649.

*Crashaw's Steps to the Temple with The Delights of the Muses* was published in 1646 with an anonymous preface, and again in 1648, with a few additions. The preface speaks admiringly not only of his poetry but of his linguistic knowledge, his proficiency in music and painting and his saintly character. His English religious verse was republished in Paris in 1652 with more additions, including some of his finest lines, those appended to "The Flaming Heart," a poem on St. Teresa, and beginning "O thou undaunted daughter of desires."

Crashaw left only a small amount of verse, but enough to give him a peculiar eminence among the writers of his day. Most of it is religious and highly individual. It reflects a mind untroubled by doubts and not much given to philosophical speculation, but vitally and ardently responsive to the Christian faith, fascinated by its implications and glorying in its paradoxes. And because Crashaw was by nature both otherworldly and sensuous, he was well qualified to capture in his poetry the spirit of Catholic worship. His thoughts are sometimes surprising and even disconcerting to modern taste, as in the conceit of Mary Magdalene weeping upward (to heaven) or the comparison of her sorrowful eyes to "portable and compendious oceans." Much of his poetry is translated from Latin or Italian, but even here his exuberance and originality can be seen, for often when he translates he transforms, sometimes adding many lines of his own invention. Some of his religious poems, those for instance on St. Teresa or on the Assumption, are justly famous, but their outstanding qualities—the eagerness and rapture, the brilliant imagery and the light, flexible rhythms—are also found in favourite secular pieces such as "Wishes, to his supposed Mistress," or "Music's Duel," which describes a contest between a lute player and a nightingale.

Crashaw was little read for 150 years after his death, though his memory was kept alive by Cowley's fine elegy. In the 19th century, however, he gained his deserved recognition and his poems were reprinted several times. They were edited again by A. R. Waller (1904) and by L. C. Martin (1927; 2nd ed. 1957).

See A. Warren, *Crashaw: a Study in Baroque Sensibility* (1930). (L. C. M.)

**CRASSULACEAE**, the orpine or stonecrop family of succulent plants, containing 15 or more genera and 500 or more species, distributed in many parts of the world. The plants, many of which are interesting garden ornamentals, are herbs or rarely shrubs, generally with thick fleshy stems and leaves adapted for life in rocky, often dry, places. The fleshy leaves sometimes are reduced to a more or less cylindrical structure, as in a few stonecrops (*Sedum*), or they form closely crowded rosettes as in the houseleek (*Sempervivum*). Correlated with their life in dry situations, much of the tissue is succulent, forming a water store that is protected from loss through evaporation by a thickly cuticularized epidermis, that is, one covered by a waxy secretion or bloom, which gives a glaucous appearance to the plant. The flowers, often red or yellow, rarely white, are usually arranged in terminal or axillary clusters, are radially symmetrical and have the same number of parts in each series. However, this number though usually 5, varies in some genera. The sepals and petals are free or sometimes more or less coalescent. The stamens are as many or twice as many as the petals. The carpels, usually free, are equal to the petals in number. In fruit they become follicles. Some species spread by means of a creeping much-branched rootstock or, as in the houseleek, by runners that perish after producing a terminal leaf rosette. In other cases small

HOUSELEEK (SEMPERVIVUM)

portions of the stem or leaves give rise to new plants by budding, as in bryophyllums (*Kalanchoe*), where buds at the edges of the leaf may form new plants.

The family is almost absent from Australia and Polynesia, and it has but few representatives in South America; otherwise it is generally distributed. Numbers of described species have been multiplied by enthusiasts, and an accurate estimate for any genus is difficult. The largest genus, *Sedum*, occurs in the temperate and colder parts of the northern hemisphere; many species occur in North America and nine in Britain. The species are easily cultivated, and they thrive in almost any soil. *Crassula* grows chiefly near the Cape of Good Hope. *Cotyledon*, a widely distributed old world genus, is represented in the British Isles by *C. umbilicus*, pennywort or navelwort. The genus *Echeveria* of Mexico and its possible segregate *Dudleya* of western North America are cultivated widely. *Sempervivum* occurs in the mountains of central and southern Europe, in the Himalayas, Abyssinia, the Canaries and Madeira; *S. tectorum*, common houseleek, or hen and chickens, is seen often in gardens. The hardy species grow well in sandy soil, and they are suitable for rockeries, old walls or edgings.

In North America the representatives of the family are most numerous from the Rocky mountains westward, especially in California where several genera are represented.

The family is allied closely to the family Saxifragaceae, from which it is distinguished by the fleshy habit and the larger number of carpels.

**BIBLIOGRAPHY.**—Alwin Berger, *Crassulaceae*; Adolph Engler and K. Prantl, *Die natürlichen Pflanzenfamilien*, 18a:352-483, fig. 183-212 (1930). Several journals are devoted to succulent plants, especially the *Cactus and Succulent Journal*; *The Cactus and Succulent Journal of Great Britain*; *The National Cactus and Succulent Journal* (England). (L. BN.; X.)

**CRASSUS** ("thick, dense"), a cognomen or third name belonging from the 3rd century B.C. onward to the Licinii, who, originally Etruscan, were the most distinguished plebeian family in Rome.

**PUBLIUS LICINIUS CRASSUS DIVES MUCIANUS** (c. 180-130), *pontifex maximus* (high priest) at Rome and consul in 131 B.C. A Mucius Scaevola by birth and a Licinius Crassus by adoption, he was a political opponent of Scipio Aemilianus Africanus (q.v.), a member of the Gracchan land commission and father-in-law of Gaius Gracchus. The first *pontifex maximus* in Roman history to undertake military command outside Italy, he was defeated and killed fighting Aristonicus of Pergamum in Asia early in 130.

**LUCIUS LICINIUS CRASSUS** (140-91 B.C.) and M. Antonius, the two greatest orators at Rome before Cicero, are vividly depicted in Cicero's *De Oratore*. Crassus made his reputation at the bar in 119 by his prosecution of Carbo, consul of 130, a conspicuous deserter from the cause of Tiberius Gracchus. The *Licinia Mucia*, passed in his consulship in 95, allowing prosecution of anyone who was alleged to be laying false claim to Roman citizenship, offended the Italians. In 91 he supported the

younger Drusus, having changed sides in politics since 106 when he had supported the consul Q. Servilius Caepio.

**MARCUS LICINIUS CRASSUS DIVES** (c. 115-53 B.C.), prominent and wealthy politician in the late republic. On the fall of Rome to Gaius Marius in 87 (when his only surviving brother was killed and his father, P. Licinius Crassus, consul in 97 and censor in 89, committed suicide) he escaped to Spain. Returning with Sulla to Italy, he fought successfully at the battle of the Colline gate in 82. His abiding jealousy of Pompey perhaps originated in Sulla's clear preference for Pompey. After his praetorship (probably in 73) he suppressed the slave revolt of Spartacus, and was consul with Pompey in 70. His wealth, derived largely from the Sullan proscriptions, gave him disproportionate influence as the creditor of indebted senators and the representative in politics of the business world (the *equites*). Apart from his early recognition of the quality of Caesar and his tenure of the censorship in 65, he achieved little in the 60s, the period of Pompey's great military achievements, and, though he may have encouraged Catiline in 65 and 64, he dropped him in 63 as soon as his schemes threatened existing capitalist tenure of property. He formed a political alliance with Pompey and Caesar (the "first triumvirate") in 60, in order to secure the passage in 59 of a law in favour of the company which collected the tithes in Asia. He supported P. Clodius in neutralizing Pompey in politics from 58 to 56, was consul with Pompey for the second time in 55 and, after that, governor of Syria. At the age of 60 he embarked on an unwarranted invasion of Parthia, and was disastrously defeated at Carrhae in 53. He was killed, as was his younger son, Publius, whom Cicero had encouraged as a promising orator but Caesar had taught to prefer soldiering. His elder son, Marcus, serving with Caesar in Gaul, survived, and through his son (and by adoption from the Calpurnii Pisones) the family name continued, down to M. Licinius Crassus Frugi, consul in A.D. 64.

**BIBLIOGRAPHY.**—Plutarch, *Life of Crassus*; ancient and modern histories of the late Roman republic (for which see works listed under CAESAR, GAIVS JULIVS). For all three Licinii Crassi listed above see F. Muenzer and M. Gelzer in Pauly-Wissowa, *Real-Encyclopädie der Altertumswissenschaft* vol. xiii (1927) 334-338, (no. 72), 252-268 (no. 55) and 295-331 (no. 68). (J. P. V. D. B.)

**CRATAEGUS:** see HAWTHORN.

**CRATER LAKE NATIONAL PARK**, in southwestern Oregon, U.S., was established in 1902 to preserve in its natural condition an area of 160,290 ac. The park's principal feature is an intensely blue lake, 1,932 ft. deep, set in a caldera (volcanic crater). The shores are almost sheer cliffs that rise from 500 to 2,000 ft., forming a nearly circular rim 6 mi. in diameter and 26 mi. in circumference.

This is the stump of a mountain, Mt. Mazama, that is believed to have once reached a height of 12,000 ft. above sea level. Centuries ago an eruption destroyed the peak, and the caldera is all that remains of it. Later intermittent outbreaks occurred, as shown by several cinder cones on the caldera floor. One of these, Wizard Island, rises 750 ft. above the water. The lake, with neither visible inlet nor outlet, is replenished by rain and snow, its level kept nearly constant by evaporation. Volcanologists consider that the volcano may be temporarily dormant.

North of the caldera there is a pumice "desert," except for which, the park's lower elevations are heavily forested; lodgepole, ponderosa and sugar pine and white and Douglas fir are the dominant tree species. At higher elevations, stands of Shasta red and alpine fir, whitebark pine and mountain hemlock are interspersed with meadows that are carpeted with wild flowers in summer.

Annual precipitation is heavy, and winter snow blows into drifts 20 to 30 ft. deep. Mammals include all three species of American deer—mule, blacktail and whitetail—black bear, pine marten, porcupine, marmot, badger, beaver and mountain beaver. Eagles, hawks, owls and grouse occur and, particularly in summer, there is an abundance of song and insectivorous birds. (Dx. B.)

**CRATERS OF THE MOON NATIONAL MONUMENT**, a tract of about 53,500 ac. in south central Idaho, U.S., set apart in 1924 as a government reservation. It is a region of cones and craters formed by volcanoes which have probably

been extinct for only a few centuries, and the name of the reservation was suggested by its resemblance to the surface of the moon. While the black lava and cinders allow only the scantiest vegetation and quickly absorb the very light rainfall, water is to be found in tunnels which were formed by eruptions through a partly formed crust. Lava stalactites and stalagmites in red and blue are striking features of these tunnels.

**CRATES**, Athenian actor and author of comedies, flourished about 450–470 B.C. He was regarded as the founder of Greek comedy proper, since he abandoned political lampoons on individuals and introduced more general subjects and a well-developed plot (Aristotle, *Poetics*, 5). He is stated to have been the first to represent the drunkard on the stage.

**CRATES**, the name of four Greek philosophers.

1. **CRATES OF THEBES** (fl. late 4th century B.C.), Cynic philosopher, was a pupil of Diogenes. He gave up his fortune and made it his mission to castigate vice and pretense. Hipparchia, daughter of a wealthy Thracian family and sister of Metrocles, forced her parents to allow her to join him in his ascetic and missionary life. He had a gift for amusing parody of serious poetry, by which he mocked other philosophers and praised the Cynic way of living. He was reputed to be the author of philosophic dramas and philosophic letters: the letters extant under his name (ed. by R. Hercher, *Epistolographi Graeci*, Paris, 1873) are spurious. His historical importance lies in the influence that he exerted on Zeno the Stoic, who greatly admired him. Plutarch's biography of him is no longer extant.

2. **CRATES OF ATHENS** (fl. early 3rd century B.C.), Academic philosopher, became scholarch or head of the Old Academy c. 270, in succession to Polemo (see *ACADEMY, GREEK*).

3. **CRATES OF MALLUS** (fl. early 2nd century B.C.), Stoic philosopher, from Mallus in Cilicia, was primarily important as a grammarian: his chief work was a commentary on Homer. Leader of the literary school and head of the library of Pergamum, he was the chief representative of the allegorical theory of exegesis, maintaining that Homer intended to express scientific or philosophical truths in the form of poetry. About 170 B.C., he went to Rome as ambassador of Eumenes II, king of Pergamum; the lectures that he delivered there gave the first impulse to the study of grammar and criticism among the Romans (Suetonius, *De grammaticis*, 2).

See C. Wachsmuth, *De Cratete Mallota* (1860), containing an account of the life, pupils and writings of Crates; J. E. Sandys, *History of Classical Scholarship*, 3rd ed. (1921).

4. **CRATES OF TARSUS** (late 2nd century B.C.), Academic philosopher, was scholarch from 131/130 to 127/126.

**CRATINUS** (c. 495–c. 420 B.C.) was generally classed in antiquity together with Eupolis and Aristophanes as the greatest of Athenian writers of comedy. Though Cratinus was probably born c. 495 B.C. some authorities put the date considerably earlier. The 21 comedies attributed to him (of which only some 400 odd fragments remain) may be divided roughly into two classes: personal and political satires, and mythological burlesques. Of the second type may be mentioned the *Odysseys*, which seems to have been a kind of skit on the Odyssey, the chorus of which was probably composed half of Odysseus' companions and half of Cyclopes; the *Thrassai*, which was an attack on the orgiastic rites of the Thracian goddess, Bendis; the *Nemesis*, which contained the story of the egg which produced Helen; and the *Dionysalexandros*, a comedy with a chorus of satyrs, which burlesqued the story of the judgment of Paris. Political satire evidently entered into the three last-mentioned plays, for in the *Nemesis* Pericles is travestied in the person of Zeus, and his mistress, Aspasia, in that of Hera; and the same statesman is referred to, in unflattering terms, in the other two. Among the plays dealing solely with personal and political satire may be included the *Panoptai* (*The All-seers*), which must have borne some resemblance to Aristophanes' *Clouds*, in that it made fun of the Sophists, and the *Putine* (*The Bottle*). In this play Cratinus defends himself against the charge of drunkenness leveled at him by Aristophanes in the *Knights*. The chorus is composed of Cratinus' friends, who attempt—successfully—to break the poet's liaison with his mistress,

Methe (drunkenness), and bring him back to the arms of his true wife, Komodia (comedy), by smashing his wine jars. The *Putine* took first prize in 423 B.C., defeating Aristophanes' *Clouds*. Cratinus' vigorous style has earned him the title of the Aeschylus of comedy.

**BIBLIOGRAPHY.**—T. Kock, *Comicorum Atticorum Fragmenta*, vol. 1, pp. 11–130 (1880); A. Körte's article in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft*, xi (1922); G. Norwood, *Greek Comedy* (1931); J. M. Edmonds (ed.), *Fragments of Attic Comedy* (1957).

**CRATIPPUS** (1st century B.C.), Greek Peripatetic philosopher, taught first at Mitylene, where Cicero made his acquaintance in 51 B.C. and where Pompey also had a conversation with him in Aug. 48 (after the defeat at Pharsalus). Moving to Athens (not later than 45), he had among his auditors there Cicero's son Marcus, whose father had chosen Cratippus as the young man's instructor. After the death of Andronicus of Rhodes, Cratippus became the most influential member of the Peripatos, though he probably was not its scholarch. Cicero, who procured Roman citizenship for him, speaks of him with high praise. The outline of his views on divination can be reconstructed from a passage quoted by Cicero (*De Divinatione*, i, 32, and ii, 52). Cratippus argues that the failure of some predictions is no disproof of prophecy, if it is matched by even a few successes not attributable to chance; but, following Dicaearchus, he rejects artificial modes of divination such as astrology and augury and accepts only prophecy in dreams or through divine afflatus. The psychological explanation is that the rational power in the soul (as distinct from the sense-faculty, which is inseparable from the body) is of divine origin and becomes strengthened when the body is inactive.

(D. J. A.)

**CRAVAT**, the name given by the French in the reign of Louis XIV to the neck scarf worn by the Croatian soldiers enlisted in the royal Croatian regiment (Fr. *Cravate*, a Croatian). The term came to be applied in England and France to any kind of a neckerchief worn by a man.

After the battle of Steenkerke (Steenkirk) in 1692, a loosely tied cravat made of linen or muslin with wide lace on the edges and worn negligently knotted with one end passed through the buttonhole was called a steinkirk. In the late 18th and early 19th centuries the cravat was an elaborately folded and lightly starched linen or cambric neckcloth worn under the collar of the shirt.

The simplification and standardization of men's dress in the late 19th and early 20th centuries made the cravat the necktie worn by men today. It is applied more specifically to the formal scarf worn with a dress suit; this cravat is folded or tied in front and the ends are tucked into the inside coat. (M. B. K.)

**CRAVEN, FRANK** (1880–1945), U.S. actor and playwright, was born in Boston, Mass. He achieved his first Broadway success in *Bought and Paid For* (1911), after which he was very popular, especially in slender comedies. Among his own plays are *Two Many Crooks* (1914), *The First Year* (1920) and *New Brooms* (1924). He played the stage manager in Thornton Wilder's *Our Town*. After 1929 most of his work was in films. (M. R.)

**CRAVEN, WILLIAM CRAVEN**, EARL OF (1606–1697), English royalist, remembered especially for his services to Elizabeth, consort of Frederick V, the elector palatine, was the eldest son of Sir William Craven, lord mayor of London (1610). He was educated at Trinity college, Oxford, and the Middle Temple, but much of his youth was spent in military service abroad. In 1632 he went to assist Frederick V, the dispossessed king of Bohemia, in the defense of the Palatinate, and there began his lifelong devotion to Elizabeth, the tragic "winter queen" of Bohemia. William, created Baron Craven in 1627, was taken prisoner by the emperor's forces in 1637 but ransomed himself and went to join Elizabeth in her exiled court at The Hague. His great wealth was their principal mainstay; during the English Civil War it was placed at the disposal of both Charles I and Charles II.

After the Restoration Craven commanded the Coldstream guards and was created Viscount Craven of Uffington and earl of Craven in 1665. The queen of Bohemia, whom it was rumored he had married, lived at his house in Drury lane, London, un-

her death in Feb. 1662. Craven held many offices under the crown, mainly honorific, and although a member of the council, he entered little into politics. But he and his guardsmen figured prominently in civic emergencies such as fires, and he prized his military command above all, retaining it until the arrival of William III's Dutch troops in London in Dec. 1688, when Craven was found stubbornly guarding Whitehall with his men, and with difficulty was persuaded to relinquish his post. He died, unmarried, in London on April 9, 1697. He was a member of the Royal society but his reputation as a patron of the arts will hardly bear scrutiny.

His brother John (d. 1648), created Baron Craven of Ryton, Shropshire, in 1643, was the founder of the Craven scholarships at Oxford and Cambridge universities, of which the first was awarded in 1649.

(H. G. Ro.)

**CRAWFORD, EARLS OF.** The house of Lindsay, of which the earl of Crawford is the head, traces its descent to the barons of Crawford who flourished in the 12th century. Sir Alexander Lindsay of Luffness (d. 1309) obtained Crawford, in Lanarkshire, in 1297. His descendant, Sir James Lindsay (d. 1397), lord of Crawford, was high chamberlain of Scotland and fought at the battle of Otterburn (1388). The chronicler Froissart tells of his wanderings after the battle. James's cousin and successor, SIR DAVID LINDSAY (c. 1360–1407), who married a daughter of King Robert II, was made earl of Crawford in 1398. His grandson DAVID (d. 1446), 3rd earl, formed with the earl of Douglas a powerful alliance which was continued by his son ALEXANDER (d. 1453), 4th earl, known as "the Tiger" or "Earl Beardie." After the murder of Douglas, Alexander opposed King James II, but he made full submission and was pardoned in 1453 shortly before his death.

Alexander's son DAVID (c. 1440–95), 5th earl, was lord high admiral and lord chamberlain, and several times ambassador to England. He was created duke of Montrose in 1488 and fought for James III at Sauchieburn (1488). The dukedom did not descend to his son JOHN (d. 1513), 6th earl, who was killed at Flodden. John's cousin DAVID LINDSAY (d. 1542), 8th earl, whose son Alexander, master of Crawford, known as "the wicked master," was sentenced to death in 1541 for attempting to kill his father, conveyed the title to his kinsman DAVID LINDSAY of Edzell (d. 1558), 9th earl. The 9th earl adopted Alexander's son DAVID (d. 1574), 10th earl, and made him his successor with the consent of the crown in 1558. The 10th earl was a firm supporter of Mary Stuart. His son and successor, DAVID (c. 1557–1607), 11th earl, took part in the risings under James VI, was converted to Roman Catholicism and communicated with Spain about an invasion of England. LUDOVIC (1600–52), 16th earl, "the loyal earl," took part in the plot of 1641 to overthrow the marquess of Argyll and supported Charles I in the Civil War. His earldom was forfeited by the Scottish parliament in 1644 and he was imprisoned. He was released by the marquess of Montrose in 1645 and served under him until the king's surrender to the covenanters. The earl died on the continent in 1652.

By the crown charter of 1642, Ludovic settled his earldom, failing his own male issue, on a distant kinsman, JOHN (1596–1678), 1st earl of Lindsay, who became 17th earl of Crawford and chief of the Lindsays. His branch of the Lindsays descended from Sir David Lindsay, grandfather of the 1st earl. A leader of the covenanters, Lindsay had marched with the Scottish army into England in 1644. He became high treasurer of Scotland in 1644 and president of the parliament, but he changed sides in 1647 and signed the Engagement. He lost all his offices when his enemy Argyll won the upper hand. In 1661 he was restored to his offices but his refusal to abjure the Covenant compelled him to resign them in 1663. His son WILLIAM (1644–98), 18th earl, also an ardent covenanter, was president of the Convention parliament of 1689. William's grandson JOHN (1702–49), 20th earl, "the gallant earl," served on the continent under Prince Eugene of Savoy and fought at the battles of Dettingen and Fontenoy. In 1740 he was made colonel of a new regiment, known then as Lord Crawford-Lindsay's highlanders and later as the Black Watch.

At the death of GEORGE (1758–1808), 22nd earl, without issue, the earldoms of Crawford and Lindsay separated. Alexander, 6th earl of Balcarres (heir male of the 16th earl), became *de jure* 23rd earl of Crawford and chief of the Lindsays, but the earldom remained dormant from 1808 until 1848 when the house of lords adjudged it to JAMES LINDSAY (1783–1869), 7th earl of Balcarres and 24th earl of Lindsay. His son ALEXANDER WILLIAM (1812–80), 25th earl of Crawford, wrote, among other works, a history of the family, *Lives of the Lindsays*, 3 vol. (1849). Alexander's only son, JAMES LUDOVIC (1847–1913), 26th earl, was president of the Royal Astronomical society in 1882. He was a collector and bibliophile, bequeathing his great stamp collection to the British museum and many valuable manuscripts to the John Rylands library, Manchester. His son DAVID (1871–1940), 27th earl, was also an authority on art and literature, published books on painting and sculpture and became chairman of the Royal Fine Art commission, founded in 1924. He took an active part in politics as well, becoming a member of Lloyd George's coalition cabinet in 1916. His son and successor, DAVID ROBERT ALEXANDER (1900– ), 28th earl, followed in the literary and artistic traditions of his three predecessors.

See A. Jervise, *History and Traditions of the Land of the Lindsays* (1882); H. T. Folkard, *A Lindsay Record* (1899). (T. I.)

**CRAWFORD, FRANCIS MARION** (1854–1909), U.S. author who treated with vividness and accuracy widely varying periods and countries, was born at Bagni di Lucca, Italy, Aug. 2, 1854, son of the sculptor Thomas Crawford (q.v.), and nephew of Julia Ward Howe, the poet. The cosmopolitanism of his work is foreshadowed by his early training at St. Paul's school, Concord, N.H.; Trinity college, Cambridge; Heidelberg and Rome. In 1879 he went to India, where he studied Sanskrit and edited the *Allahabad Indian Herald*. Returning to the United States, he continued to study Sanskrit at Harvard university for a year, contributed to various periodicals, and in 1882 produced his first novel, *Mr. Isaacs*, a brilliant sketch of modern Anglo-Indian life mingled with a touch of oriental mystery. This book had an immediate success, and its author's promise was confirmed by the publication of *Dr. Claudius* (1883). After a brief residence in New York city and Boston and travel in Turkey and elsewhere, Crawford in 1883 returned to Italy, where he made his permanent home and about which he wrote numerous novels, including the excellent series *Saracinesca* (1887), *Santi Ilario* (1889) and *Don Orsino* (1892). His interest in his adopted country is also revealed in his historical works, *Ave Roma immortalis* (1898), *Rulers of the South* (1900)—renamed *Sicily, Calabria and Malta* in 1904—and *Gleanings from Venetian History* (1905), in which his intimate knowledge of local Italian history combines with the romanticist's imaginative faculty to excellent effect. Among the most celebrated of his novels are: *A Roman Singer* (1884), *A Tale of a Lonely Parish* (1886), *Paul Patoff* (1887), *The Witch of Prague* (1891), *Via crucis* (1898), *In the Palace of the King* (1900), and *The White Sister* (1909). In his American novels such as *An American Politician* (1885) he was probably least successful. Nevertheless, he was always a gifted narrator, and his romances with their picturesque backgrounds and dramatic characterizations were very popular. In *The Novel—What Is It?* (1893) he set forth his belief that the novel should be "a pocket theatre" for entertainment only. It was but natural, therefore, that *A Cigarette Maker's Romance* (1890) should be effective on the stage, and that in 1902 an original play from his pen, *Francesca da Rimini*, should be produced in Paris by Sarah Bernhardt. He died at Sorrento April 9, 1909.

For criticism and bibliography see F. T. Cooper, *Some American Story Tellers* (1911). For biography, see Maud Howe Elliot, *My Cousin F. Marion Crawford* (1934).

**CRAWFORD, ISABELLA VALANCY** (1850–1887), the first Canadian woman poet of note, was born in Dublin, Ire., Dec. 25, 1850. The daughter of a physician who emigrated to Canada in 1858, she spent most of her girlhood in the picturesque Kawartha lakes district of Ontario. She received an excellent education in the classics and was widely read in French and Italian. The last years of her life she and her widowed mother lived over a

grocery store in Toronto, meagrely sustained by the sale of her stories and poems. Most of these appeared in Toronto newspapers, a few in U.S. magazines. A novel was serialized in the *Toronto Evening Globe*. Her only book was a paper-covered collection of her poems, published at her own expense in 1884, *Old Spookses' Pass, Malcolm's Katie, and Other Poems*. *Old Spookses' Pass* describes a cattle stampede in the Rockies, vigorously and vividly related in an irksome but consistent American cowboy idiom. *Malcolm's Katie* is a sentimental and melodramatic romance competently handled in the manner of Tennyson. Her best narrative and descriptive passages—mainly those with Canadian themes and settings—are marked by energy of rhythm and boldness of imagery. She died in Toronto, Feb. 12, 1887. A collection of her poems was published in 1905.

See Katherine Hale, *Isabella Valancy Crawford* (1923); C. F. Klinck and R. E. Watters, *Canadian Anthology* (1956). (A. M. BE.)

**CRAWFORD, THOMAS** (1814–1857), U.S. sculptor whose best-known work is the colossal "Statue of Freedom" on the dome of the capitol building in Washington, was born in New York city, March 22, 1814. Crawford was trained as a stonemason in the marble yards of Frazer & Launitz in New York. In 1835, he went to Rome where he had some instruction from Bertel Thorwaldsen. He made his home there for most of the remainder of his life. Crawford designed sculpture for the senate pediment of the capitol symbolizing the progress of civilization in America, and a pair of bronze doors, but he died before these were completed. He also designed the Washington monument in Richmond, Va., and the statue of Beethoven in Boston. He died in London, Oct. 10, 1857. At the time of his death his reputation rivaled that of Hiram Powers and Horatio Greenough as a leading American sculptor. His work, however, like theirs, did not remain long in popular favour after his death. The novelist Francis Marion Crawford (q.v.) was his son.

**CRAWFORD, WILLIAM HARRIS** (1772–1834), U.S. senator, cabinet member and presidential candidate, was born in Amherst county, Va., on Feb. 24, 1772. His family moved to South Carolina and then to Georgia. After study and teaching in an old-field school, Crawford attended Carmel academy, directed by the famous Presbyterian minister Moses Waddel. He taught in and was rector of the Richmond academy in Augusta and began to practise law in 1799. Coauthorship of a digest of the Georgia laws and service in the Georgia house of representatives (1803–1807) preceded his election to the U.S. senate in 1807. He was re-elected without opposition in 1811. Crawford was a strong advocate of the Bank of the United States and approached the views of the "War Hawks" in the dispute with Great Britain. He served as president pro tempore of the U.S. senate (1812–1813) and as minister to France (1813–1815). President Madison appointed him secretary of war in Aug. 1815, and in Oct. 1816 he became secretary of the treasury, a post he held until March 1825. In 1816, in spite of his disavowal of candidacy, Crawford received only 11 fewer votes in the presidential caucus than did James Monroe. Before the end of Monroe's second term, however, the political picture had changed and there were four strong candidates—John Quincy Adams, Henry Clay, Andrew Jackson and Crawford. As none won a majority of the electoral votes the choice went to the house of representatives, which chose Adams. Crawford's ruling as secretary of war on some of the provisions of the treaty with the Creek Indians had incited the ire of Andrew Jackson, who seems to have sparked the bitter intraparty strife that led to the choice of Adams. Crawford's ill health, resentment in the north against the continued control of the presidency by the south, popular discontent with caucus nominations, and the uncertainty of Crawford's position on internal improvements—all these factors seem to have had a bearing on the outcome. After the election Crawford declined President Adams's offer to remain as secretary of the treasury.

From 1827 until his death on Sept. 15, 1834, he was judge of

the northern superior court circuit in Georgia.

Crawford was of imposing stature and possessed great charm and conversational powers. He was deemed a skilful political organizer but he never achieved great popularity. His independence of mind and his refusal to adhere to party principles merely for the sake of party did not endear him to some of his contemporaries. A slaveowner, he supported slavery where it existed but indicated that if he lived in a region where it did not exist he would oppose its establishment. In later years he became a strong advocate of state rights but denounced nullification and secession, preferring instead the calling of a constitutional convention to deal primarily with the tariff question. On his 1,200-ac. plantation, "Woodlawn," not far from Lexington, Ga., for more than 25 years he carried out many experiments with plants and seeds imported from other countries and various parts of the United States. (C. C. Mo.)

**CRAWFORDSVILLE**, a town and seat of Montgomery county, Ind., U.S., is located on Sugar creek, 44 mi. W.N.W. of Indianapolis. It was founded in 1823 and chartered in 1865. The leading industry is publishing, printing and bookbinding. Manufactures include wire fencing, nails, plastics, pellet mill dies, lift trucks, gray iron castings, brick, caskets, sintered metal products, bottle caps, pre-cut houses and screw machine products.

Wabash college for men was founded there in 1832 by Presbyterian missionaries. Crawfordsville was the home of Lew (Lewis) Wallace, author of *Ben Hur*, Henry S. Lane, statesman, and Maurice Thompson, poet and novelist. Historic memorials include several college buildings, the Lew Wallace study and the Henry S. Lane mansion. The city maintains two recreational centres, a municipal golf course, a park system and airport. For comparative population figures see table in INDIANA: Population. (T. G. G.)

**CRAWLEY**, an urban district formed in 1956 as a result of the development of the New Town designated in 1946, in the Horsham parliamentary division of West Sussex, Eng., 9 mi. S. of Reigate and 7 mi. N.E. of Horsham on the main London to Brighton road. Pop. (1951) of civil parish 7,000; of Crawley New Town (1961) 54,065. The proposed population of the New Town is 55,000. Area of district 7.0 sq.mi.; of Crawley New Town 9.3 sq.mi. Crawley New Town lies in West Sussex and East Sussex and a small part of the industrial area is in Surrey. To the south are the forests of St. Leonards, Tilgate and Worth, and nursery gardens and woods covering about 465 ac. are being retained while most of the farms were built over. Crawley received a charter from King John in 1202 and its medieval buildings have been preserved. The old industries include light engineering and wood-working; new ones are chiefly engineering (making machinery, elevators), electrical (hearing aids, electronic apparatus), colour printing and inks, plastics and food processing. See also New Towns.

**CRAYER, CASPAR (GASPARD) DE** (1534–1669), Flemish painter, who was strongly influenced by his friend Rubens, was born at Antwerp on Nov. 18, 1534. He was a pupil of Raphael Coxie in Brussels, where he became a master in the painters' guild in 1607 and resided as a much-honoured citizen until 1664. In 1635 he was appointed court painter to the cardinal infant Ferdinand, for whose triumphal entry into Ghent he had designed decorations; after Ferdinand's death in 1641 he received the title of a painter to the king. In 1664 he moved to Ghent where he died on Jan. 27, 1669. De Crayer was the painter of a large number of altarpieces which were produced with the help of many assistants and still abound in the churches and museums all over Flanders and elsewhere in Europe. His pictures of secular subjects are rare. His artistic development runs parallel in various respects to that of Rubens, but he surpassed all other close followers of Rubens in thoughtfulness and compositional skill. His portraits are invariably excellent. (W. Sw.)

**CRAYFISH** (CRAWFISH or CRAWDAD) are crustaceans allied to and resembling lobsters, and like them, belonging to the order Decapoda. They are found in fresh waters of all the continental land masses except Africa. Crayfishes range in size from the about 1-in.-long *Cambarellus diminutus* of Alabama to the giant 16-in., 8-lb. *Astacopsis gouldi* of Tasmania. In some parts of the world,

the marine spiny or rock lobsters are called crawfish. Freshwater shrimp of the genus *Macrobrachium* are occasionally confused with crayfish; however, in these animals the heavy pincers are on the second, rather than the first, pair of legs. The Decapoda, one order of the larger subclass Malacostraca, is a ready source of study material in zoology classes. In particular the crayfish, because of its wide availability and ease of capture, has become a classic subject for dissection, furnishing information on malacostracan anatomy in general.

Although most species of crayfishes frequent streams, ponds, or lakes, where they find shelter under stones, in debris, or among vegetation, a number of them are found in temporary bodies of water. In fluctuating ponds or ditches they construct burrows as the water level descends. These burrows (often mistakenly called snake holes) reach the water table and may extend eight feet or more below the ground surface.

Although there are no truly terrestrial crayfish, there are a number of species that spend their entire lives in and about the mouths of their burrows. The soil that is removed from their excavations is frequently piled haphazardly round the opening, but characteristic cylindrical chimneys, often exceeding one foot in height, are constructed at the mouths of the burrows of some species. In the southeastern part of the United States many moist soil areas support such large populations of crayfishes that they are called "Crawfish lands." A number of blind albinistic crayfishes oc-

replace lost parts, especially appendages and eyes, which have been either broken off accidentally or sacrificed to a clutching enemy (see also REGENERATION).

Although in certain parts of the world crayfish are food for man and constitute important items in the diets of fish, amphibians, reptiles, birds, and mammals, they are frequently highly destructive. Burrowing forms in the southeastern part of the United States destroy agricultural crops, disfigure lawns, and burrow into earthen dams; in Hawaii the recently introduced Louisiana red crayfish has caused considerable damage in the taro fields. Certain species serve as intermediate hosts in the life cycle of the parasitic lung fluke of mammals.

The crayfish are classified into three families, the Astacidae, inhabiting the Northern Hemisphere; and the Parastacidae and Austroastacidae, in the Southern Hemisphere, the latter family being confined to Victoria, Austr. More than half of the described crayfishes occur in North America; they include about 200 species and subspecies of the genera *Procambarus*, *Orconectes*, *Cambarus*, *Cambarellus*, and *Pacifastacus*.

The crayfishes of Britain and much of Europe belong to the genus *Austropotamobius*. Several species of the genus *Astacus* are also found on the European continent. The genus *Cambaroides* occurs in eastern Asia and Japan.

**CRAYON DRAWING** is the general name given to broad-line drawing in black or coloured materials; formerly natural mineral substances cut into sticks were used, but after the early 19th century fabricated materials commonly were substituted. There is some looseness in the use of the term, partly because the French meaning of *crayon* includes the common graphite ("lead") pencil, partly because pastel (*q.v.*) was often called crayon before the pastel technique separated from line drawing. In the 20th century the growing use of the wax crayon of childhood as a serious artist's medium, and a common-sense desire for clarity, led to use of (1) the name crayon for solid (normally uncased) mediums having a waxy or fatty binder; (2) the name pastel is reserved for mediums having little or no binder and made in a range of values within a given colour; (3) fabricated chalk is the term used for mediums having a nongreasy binder (normally at full chroma without variation of values); and (4) cased mediums are called coloured pencils. Crayons and fabricated chalks are much less likely than pastels to be loaded with clays, kaolin or plaster of paris, but every pigment calls for its own extender or binder, or both, to produce optimum ductility.

There is also a tendency to define according to use as well as by material, so that the name pastel might be used for any dry coloured drawing medium when it is functioning as pastel (*i.e.*, covering the whole surface of the paper support); and the same medium might be called crayon or fabricated chalk when it is functioning in a linear way and not covering the whole surface.

Charcoal, originally a simple by-product put to draftsmen's use, has long been made for artists from split willow sticks. It is so devoid of adhesive power that it is of small use for permanent work unless sprayed with fixative; its brittleness and occasional failure to mark (because of uneven hard layers in the wood) present difficulties. Yet charcoal has served well as a preliminary sketching medium, easily erased after its lines were confirmed with ink. In modern times, powdered charcoal has been compressed into crayons so dense that they scarcely need a binder.

Oiled charcoal, made by soaking the sticks in linseed oil, gives a rich black adhesive mark. However it must be used at the right time: after the surplus oil has dripped away but before the oil in the charcoal has oxidized, leaving it again dry and brittle. The Tintoretto family, Giacomo Cavedone (1577-1660) and other 17th-century artists, as well as some in the 19th century, favoured oiled charcoal. Students who care to distinguish, after the fact, between lines in charcoal and those in black crayon will find under magnification that the particles of charcoal tend to lie in the hollows of paper, while those of crayon stick to the high spots

CRAYFISH (ORCONECTES VIRILIS)

cur in the subterranean waters of the United States and Mexico. Among them is the unique *Troglocambarus maclanei* that clings, upside down, to ceilings of underground water systems in Florida. Most crayfishes are more active at night than during the day.

The life histories of relatively few species are known; however, it is evident that the European crayfishes mature much more slowly and have a considerably longer life span (seven or eight years in northern Europe) than do those species living east of the Rockies in North America (one to four years). When the eggs—less than a dozen to more than 1,000—are laid, each, enclosed in a separate capsule, is affixed by a slender stalk to the abdominal appendages of the female. Development proceeds as the eggs are aerated as the female swings the stalks back and forth in the water. Within a few weeks to several months, depending in part upon the temperature of the water, transparent miniatures of the adult hatch. Each offspring is still attached to the mother by a slender thread.

Like other arthropods crayfish grow only when their exoskeleton is shed, and at the first molt the young, although no longer attached to the mother, cling to her. With subsequent molts and further growth they become independent, feeding upon both living and dead plant and animal matter. Sexual maturity is attained within a few months in some species but requires several years in others. The crayfish—like its ally the crab—has the ability to

of paper. Oiled charcoal leaves a greasy ring or parallel lines around or along its course.

**History.**—Before the day of fabricated chalks, the adhesive power of natural black chalk, an impure carboniferous slate, made it preferable to charcoal as a drawing medium except where ease of erasure was desirable. In occidental art it is of record since Cennino Cennini (c. 1370–c. 1440); it was the standard material in Renaissance and post-Renaissance practice for studying details, especially figures. Black chalk heightened with white (gypsum or soapstone) was being used by 1500 on blue Venetian paper; red chalk (from hematites and other iron oxides) was in use before 1500 by Leonardo da Vinci. Red began to be combined with black and then with white chalk early in the 16th century, and in the time of Federico Barocci (1528–1612) the combination of these three with blue paper was complete in its suggestion of greater range and variety of colour, its rich texture and its power to give the sense of third dimension. It remained for Rubens, Batista Tiepolo and Antoine Watteau to carry this three- or four-toned crayon drawing to greater heights.

Most of the old masters used crayon (natural or fabricated chalk) for drawing at one time or another. Fra Bartolommeo, Michelangelo, Andrea del Sarto, Tintoretto, Jacopo da Pontormo, Lucas van Leyden, Correggio, the young Rembrandt, the Ruisdaels, Jan van Goyen, Batista Piazzetta and Hubert Robert were among the most brilliant and also consistent users of red or black crayon or combinations. In the early 16th century there occurred with the Clouets in France and Hans Holbein on his English visits a great activity in portrait drawing in coloured chalks. The Clouets used red and black, often blending the two colours by rubbing or by association of small strokes; their followers would even wet the chalk drawing, thus forming a sort of unifying pale wash. Holbein used red, black, brown and yellow crayons, often on tinted grounds, and variously added metal point and pen lines for reinforcement.

Watteau, building in part upon Rubens, became the great master of the method called *à trois crayons*. He knew "how to commingle the red, black and white strokes with the tone of the paper so as to suggest the illusion of a natural garment of colour, how to rub the vermilion chalk on the black with the finger or a stump or a rag, so that a lovely tone [should] evolve, how to draw those expressive lines that positively sparkle with the living accent, how to judge the exact tones of white that [should] lighten the contours and the shadows" (M. C. Salaman). Watteau sometimes wet his *sanguine* (red crayon) for an especially strong touch in a nostril or the corner of an eye—a usage not unlike emphasizing a black chalk drawing with touches of oiled charcoal as some 17th-century men had done. Nicolas Lancret, J. B. J. Pater, François Boucher, Honoré Fragonard, J. B. Greuze and Clodion (Claude Michel) in their various ways followed Watteau's method but never surpassed his result.

Neo-classicism tended to dislike the sensuous and quasi-naturalistic colour of the three-chalk technique, but found black and white on blue paper useful for its bas-relieflike figure drawings (as in the work of Pierre Prud'hon). Nicolas Conté's slightly greasy fabricated crayon, developed about 1790 (not the first fabricated medium but probably the first with a trade name), was ready to hand. Yet such a man as Goya (who had drawn mostly with the brush) in his late years took up red chalk.

Richard Wilson and Thomas Gainsborough had used black and white on blue paper for serene or poetic landscapes; but Gainsborough often mixed techniques or applied his white heightening wet with a brush. William Hogarth occasionally used chalk; and John Singleton Copley, after his move from America to Britain, prepared many of his paintings with large studies in the three-tone method. John Linnell (1792–1882) was an early exponent of the 19th-century way of independent drawing in crayon; his landscapes in coloured chalks, often on tan paper, foretold Impressionism (though the Impressionists seldom drew).

Eugène Delacroix was a master of black crayon both for rapid notations (he said a young artist must learn to draw a man falling from a window before the body hit the ground) and for careful preparations for his paintings and for the *Hamlet* and *Faust*

lithographs. Honoré Daumier freely mixed red or black chalk line with ink or colour brushwork. Jean Millet and Puvis de Chavannes rather soberly used black chalk for landscape and figure drawings; Millet's were often made for their own sake for sale, and occasionally had a little colour. Renoir used red chalk with much of the 18th-century feeling for its delights but on a large scale and with a bolder hand. Probably the most fascinating 19th-century draftsman in crayon was Edgar Degas, who, though he also used charcoal at the black end and pastel at the coloured end of the gamut, made quantities of studies which, in their not covering the paper support, qualify fully as drawings but have some coloured lines or areas. Toulouse-Lautrec apparently used coloured pencils and wax crayons as well as fabricated chalks and pastels.

Georges Seurat not only used coloured crayon but was an inventive crayon draftsman in black and white. His drawings in tone, almost without line and using the bold grain of his paper as a refracting surface, made white spaces as important as black; by the same token he was the modern user of creative erasure, probably invented in the 16th century by Battista Naldini and seldom used until Seurat resurrected it. Odilon Redon and Charles Sheeler are in his line of succession. The early black-chalk figure drawings of Vincent van Gogh are like a heavy-handed version of some Seurat figures in their study of mass and value rather than action or line.

Around the fringes of Impressionism, both before and after, there were draftsmen using specks of coloured crayon or pastel on toned grounds or coloured paper: Whistler, Hans von Marées, Jean F. Raffaelli, Pascin, even the young Picasso. The great illustrators of the late 19th and early 20th centuries, especially after photomechanical reproduction was perfected, made as fine use of broad crayon as the mid-19th century illustrators had done of pen and ink. In the time of George Bellows it became common for illustrators to draw with lithographic crayon, the fattest and blackest of all, for half-tone reproduction; Käthe Kollwitz, an all-round graphic artist, was a master of such broad crayon handling and so was Henri Matisse.

The long-familiar convenience of chalk (or latterly of compressed charcoal and other fabricated media) for figure-study drawing has appealed much to sculptors. There is almost a direct line of descent of red-chalk drawings from Michelangelo to Bouchardon and Alfred Stevens and Aristide Maillol (whose sometimes independent drawings were made on a heavy paper of his own fomentation). Another sculptor, Henry Moore, has been the prime user in his drawings of wax crayons and of modern "negative" or resist techniques based on them and largely developed in commercial-art practice: lines or areas in coloured wax or (where a negative effect is wanted) white crayon are first drawn; ink or water colour superimposed then refuses to cover the waxy area which shows through and may be further differentiated by scratching it. See also DRAWING (TECHNIQUES OF); PASTEL.

**CRAZY HORSE** (Indian name, TASHUNCA-UITCO) (1849?–1877). American Indian chief of the Oglala tribe of the Sioux, considered by many to be the ablest Sioux tactician. He participated in the Fetterman massacre (Dec. 21, 1866) and the disastrous Wagon-Box fight (Aug. 2, 1867). He was a leader of the Indians in the Sioux war of 1875–77, when various Sioux bands refused to settle on reservations. Gen. George Crook surprised the Indian camp in mid-winter and drove off its ponies. Crazy Horse recovered the herd and moved north to the Rosebud river. There he defeated Crook in June 1876, forcing him out of the campaign. He joined Sitting Bull and other Sioux on the Little Bighorn river and was prominent in the annihilation of the force led by Col. George A. Custer (q.v.). After that victory the Sioux bands separated. While Sitting Bull retreated to Canada, Crazy Horse remained in Sioux country. He was pursued by Col. Nelson A. Miles until forced to surrender in the spring of 1877. Suspected of conspiring to lead the Oglalas on the warpath again, he was arrested in

*Left:* Studies from a skeleton by Jacopo da Pontormo (1494-1556), Florentine. The slight rubbing of the crayon strokes gives an almost ivory texture to the bones. In the Uffizi gallery, Florence. *Right:* Figure study for the "Battle of Zara" by Tintoretto (1518-1594), Venetian. The use of rough paper and broad strokes produces an effect of rugged strength. Uffizi

Portrait of M. Pienne by François Clouet (d. 1572), French. Sharpened red and black crayons were used to produce a network of fine lines and dots. Houghton Library, Harvard university

## CRAYON DRAWING, 16TH-19TH CENTURIES

*Left:* Female head by Federico Barocci (1535?-1612), Italian. Barocci used black and white, sometimes also red and yellow, crayons on blue paper, a technique which became popular in the 18th century. In the Musée de Beaux-Arts, France

Two heads by Giovanni B. Piazzetta (1682-1754), Venetian. Black and white on blue paper in a typical drawing made independently of painting. In the collection of János Scholz, New York

Study for a portrait of Jules Finot (or James Tissot?) by Edgar Degas (1834-1917), French. In such descriptive drawings Degas worked out his compositions by repeated trial. Fogg Museum of Art, Harvard university

Sheet of studies by Antoine Watteau (1684-1721), French. Typical of the accumulated notes from which Watteau chose motives for painting, this drawing has one figure all in black chalk, another all in red, others in red, black and white. There is also the use of pencil and wash. In the Rijksprentenkabinet, Amsterdam

"Le Pont de Courbevoie" by Georges Seurat (1859-91), French. Texture is produced by dragging the crayon broadside to the grain of the paper, with occasional finer work by the point of the crayon. Collection of Francis Kettaneh

#### WATTEAU, SEURAT AND MATISSE

"Reclining Nude" (sketch for the "Pink Nude") by Henri Matisse (1869-1954), French. Charcoal. Deliberate smudging of the broad lines, and highlighting by erasure in two places, produces a sumptuous inner modeling. In the Cone collection, Baltimore Museum of Art (Maryland)

Sept. 1877. Faced with imprisonment after being promised limited freedom, he presumably tried to break away from his guards and was killed, Sept. 5, 1877.

See Mari Sandoz, *Crazy Horse: the Strange Man of the Ogilala* (1942, 1955). (D. E. W.)

**CREASY, SIR EDWARD SHEPHERD** (1812–1878), English historian and lawyer, was the author of the popular *Fifteen Decisive Battles of the World* (Marathon, Syracuse, Arbela or Gaugamela, the Metaurus, the defeat of Varus, Châlons, Tours, Hastings, Joan of Arc's victory at Orléans, the Spanish Armada, Blenheim, Poltava, Saratoga, Valmy and Waterloo), first published in 1851. He was born Sept. 12, 1812, at Bexley, Kent, educated at Eton and King's college, Cambridge, elected fellow of King's (1834) and called to the bar at Lincoln's Inn (1837). He became professor of history in the University of London in 1840, and in 1860 was appointed chief justice of Ceylon and knighted. He retired in 1875 and died in London, Jan. 27, 1878. His other books include an *Account of the Several Invasions of England* (1852) and *Rise and Progress of the English Constitution* (1853).

**CREATION, MYTHS OF.** Myth, in primitive society, does not represent abstract philosophizing concerning the ultimate origin of the universe, or the beginning and essential nature of man; nor, indeed, is it a fanciful explanation of how the universe came into existence (as was formerly supposed), though fictitious incidents may be recorded frequently in the narrative. The primitive mind considers that things are as they are because they have been so created and ordained, and primitive interest in the past course of events is centred upon their bearing on present affairs and realities. This is demonstrated in myth by the belief that the spoken word is an oracle, and that the repetition of the word sets free the creative and re-creative power with which it is replete.

Thus, the numerous myths of origin which recur in primitive states of culture throughout the world are not the expression of an innate inquisitiveness about the problem of creation, an intellectual search for a "first cause" such as occupied the minds of the Ionian thinkers. Neither are they imaginative episodes such as Plato employed to give a clearer vision of the truth they were intended to convey, and to fill a gap in philosophical reasoning and empirical knowledge. Primitive myths originate from the conviction that the creation of the world had a permanent effect on subsequent behaviour and on the structure of society. Thus, among the Australian aborigines, the mythic past is concerned largely with the "dream time of long ago," the Alcheringa, when the ancestors brought the existing configuration of the country into being, created the various human groups and ordered their laws, customs, beliefs and the social and religious organization before they retired to the sky-world. What was then initiated has to be enacted by their descendants in the prescribed cultus because the well-being of the tribe depends upon the repetition of the events in the creative period. So the myth lives on in its ritual, and the creative process is an ever-present reality giving stability to the social structure and institutions.

The problem of ultimate origins and the idea of creation *ex nihilo* lie outside the range of the primitive mind; in cosmological myths all things are assumed usually to have been created from an existing order, such as a primeval ocean. According to one of the myths of the Crow Indians of Montana, for instance, long ago there was only water in which were ducks. Then the Sun as the creator, who has become merged with the "transformer" known as the Coyote, told them to dive into the waters and from the mud on the webbed feet of one of them he created the earth and peopled it with living creatures. This episode is a typical example of the cycle of creation stories associated with the Sun-Coyote as a "transformer" in the myths of the Crow and of the Thompson River Indians of British Columbia. They have parallels throughout the new world, in the cosmological myths in southern and eastern Australia, in Africa and the Pacific. In these myths the problem of a beginning in time or of time never occurs in the sense in which it has vexed the minds of later sophisticated thinkers. Creation centres in the production of the earth in its present form and the way it was made habitable and serviceable for human beings.

**Creation Myths in Egypt and Mesopotamia.**—In the great collection of myths and liturgies that recur in the texts belonging to the 3rd and 2nd millennia B.C. in Egypt, Mesopotamia, Syria and Palestine, the drama of creation is set forth as a series of births and struggles in the realms of the gods. In Egypt, the cosmic order was said to have been established from dry land which appeared out of the primordial abysmal ocean, deified as Nun. This is hardly surprising as in the Nile valley the annual inundation was the most significant event upon which vegetation and the economy of the country depended.

Amon, god of the Sun and father of all the other gods, also arose out of the abyss; according to one legend he appeared as a child sitting in a lotus bud. In Heliopolitan theology he was later known as Ra, and was said to have given birth to the gods and goddesses and performed his acts as creator on the primeval hill at Heliopolis where his temple was built afterward. In Memphite theology, however, the gods were regarded as manifestations of the uncreated Ptah, who produced them in conjunction with Nun, and who created all other objects in the world from his own thought.

In all these involved myths of origin, Egypt was represented as the centre of the universe, the creative process being renewed daily, as it was supposed, by the rebirth of the Sun, and annually by the rise and fall of the Nile. In Mesopotamia, on the other hand, conditions were far less predictable; there was constant danger from torrential rain, scorching winds and the uncertain behaviour of the Tigris and Euphrates. Therefore, although there was a similar conception of creation from a primeval watery abyss (*Apsu*), the world and mankind came into being from a violent conflict between the older and younger generations of the gods. This is related in the *Enuma elish*, the Babylonian creation epic which is recorded in its later form in the cuneiform texts of the 7th century B.C. but which goes back to the middle of the 2nd millennium, and beyond this to the ancient Sumerian story of about 3000 B.C. In the later version Marduk, the god of Babylon and head of the pantheon, made the sky and the earth from the two halves of the body of Tiamat, the Chaos-dragon personifying the powers of evil, whom Marduk had overcome in a long and fierce battle. In none of the Sumero-Babylonian creation stories were the gods actually creators in a transcendental sense, being themselves an integral part of the universe and a product of its creative process. Moreover, they created mankind primarily to supply themselves with sacrificial nourishment and were dependent upon their own creatures for their sustenance. No Mesopotamian deity was regarded as the source of all existence as were Ra or Ptah in Egypt. Creation was essentially a political enterprise, and the status of the gods concerned was determined by that of the cities over which they presided, rising and falling with the fortunes of their chief cult cities.

**Anatolia and Syria.**—A group of myths found in the Hittite and Hittite texts of Anatolia have parallels in the Mesopotamian cycles; e.g., the Hittite cultic myths of Telipinu and of the *illuyankas* dragon who was vanquished by the weather-god of the Hatti are of the same type as the Babylonian epic of creation and like it were associated with the New Year festival; their theme is also similar to the Tammuz-Ishtar myths, and to the Osiris-Isis-Horus myths in Egypt. However in none of the texts from Anatolia have creation stories been found. The same is true of Syria: the Ugaritic texts excavated at Ras Shamra depict a shadowy creative supreme being, El, who dwells in a cosmic paradise and is head of the Canaanite pantheon, but they make no mention of the creation of this paradise or of the manner in which the pantheon emerged.

**Hebrew Creation Stories.**—Genesis gives two accounts of the creation. The story in Gen. i and ii, 1–4 was compiled by the Priestly school (see *PENTATEUCH*) in the 5th century B.C. Although it was based on the Babylonian *Enuma elish* to a considerable extent, the ancient mythology lay deep in the background. Thus the heaven and earth were formed out of a primordial ocean, as in the Babylonian myth, but the Hebrew *tehom*, or "deep," was not personified like *Apsu*. Moreover it was the Spirit of God which hovered over the waters, dividing the light from the darkness and the upper from the lower firma-

ment; alone he created the heavens and the earth. No mention is made of the struggle between Yahweh and Rahab and Leviathan. The succession of creative acts occupying six days followed virtually in the same order as that in the Babylonian bilingual texts and the *Enuma elish*, culminating in the creation of the human species. This ended with a sabbatical rest of the Creator on the seventh day, thereby giving divine sanction for the observance of the Sabbath; moreover, the didactic character of the myth with its repeated refrain is indicative of a liturgy. The closely associated dragon mythology in the "enthronement psalms" accords with the victory of Marduk over Tiamat, interpreted in terms of the vindication of the creative work of Yahweh (Ps. lxxiv, 12-14; cxxxvi, cf. Isa. li, 9), recited doubtless in the Temple at Jerusalem at the annual festival.

The pre-exilic paradise story in Gen. ii, 4-25 is less liturgical and more Palestinian in its cosmology, though it too has Babylonian affinities. In its present form it is a combination of two myths: one concerning the preparation of the world for the use of man, from the southern kingdom of Judah, the other, relating the story of the temptation, from the northern kingdom of Israel. The earth as a barren waste is represented as already in existence, and on it Yahweh-Elohim planted a delectable garden "to the east in Eden," watered by four rivers which included the Tigris and Euphrates (Hiddekel), and by a mist that descended upon the ground. Man was made first from the dust of the soil (*adama*) and into his nostrils the Creator breathed the breath of life. The animals and birds were then created to be his companions, but as they failed to meet his needs a female human partner, Eve, was given to him. Two trees stood in the midst of the garden, sacred and therefore taboo because their fruits had supernatural qualities bestowing divine knowledge and immortality. It is not clear whether the eating of the forbidden fruit at the instigation of the wily serpent, and the subsequent expulsion from Eden, were part of the original myth. The series of events leading up to it have parallels in the Babylonian Adapa and Gilgamesh legends, but the setting is Palestinian, interpreted in accordance with the ethical monotheism of the prophetic movement in Israel. (See also ADAM AND EVE; EDEN.)

**Iranian Cosmology.**—Contemporary with the monotheistic conception of creation held by the Judaic prophets and their priestly successors was that of Zoroaster, initiated probably about the 6th century B.C. He also declared that one all-wise lord and sovereign ruler of the universe (Ahura Mazda) was the sole creator and sustainer of creation. Man was the crowning act of creation, the whole cycle of existence having been called into being to enable him to soar higher and higher, and at last enjoy eternal bliss. Every phenomenon, spiritual and material, was attributed to Ahura Mazda, who determined the path of the stars, upheld the earth and the firmament, caused the moon to wax and wane, and created light and darkness. In him the primal precosmic twin spirits of good, or righteousness, and evil (Angra Mainyu, the Druj, later known as Ahriman) meet in a higher unity. The eternal polarism, however, was not originally a cosmic or absolute dualism of good and evil because the twin spirits had no independent existence apart from Ahura Mazda, and in the end his righteous will was destined to prevail. In later Avestan literature Ahura Mazda is considered to be creator only of that which is good. He is in perpetual conflict with Ahriman, now considered to be creator of all that is evil. Each of their battles was to last 3,000 years and constituted a preordained phase in the history of the universe. The ultimate issue, however, was never in doubt: at the final consummation, the righteous reign of the all-wise lord would be established and the Lie and all his works would be vanquished and destroyed. Then the entire creation would attain the height of perfection in a renovated world, and enter upon a new cycle free from evil, Ahura Mazda becoming all-in-all. In the Sassanian period the Zervanites attempted to mitigate this dualism by again making Ormazd (Ahura Mazda) and Ahriman coeternal emanations from a primeval being, whom they called Zurvan, infinite Time. Their doctrine was rejected as heretical by all orthodox Parsis.

**Greek Cosmology.**—Unlike the Hebrews and the Iranians,

the Greeks never resolved creation into a unified process in relation to the Olympian gods, none of whom assumed the role of creator comparable to that of Yahweh or Ahura Mazda. In the 6th century B.C. the Ionian thinkers broke away entirely from the polytheistic tradition in an intellectual search for a first cause of, and sustaining principle in, the universe and its processes without reference to gods and theogonies. Even Zeus, though called "the father of gods and men" was not originally a creator. Thus, in the cosmology of Hesiod, about the 8th century B.C., he was son of Cronus and the god who was assigned dominion over the heavens, while Poseidon ruled the seas and Hades the nether regions, the earth being their common property. This appears to have been the Greek variant of the Anatolian Kumarbi myth in the Hurrian texts, which were diffused from Asia Minor probably in the middle of the 2nd millennium B.C. The earth was represented as a vast plain encircled by streams (Oceanus) resembling the Egyptian Nun, from which the gods and mankind sprang. When the gods took up their abode on Mt. Olympus they were organized on the model of Indo-European chieftains, but they made no claim to have created the world.

As the Aryan, Anatolian and Aegean elements in the cosmology found a common centre in Zeus as the sky and weather god, the Olympian leader, the "cloud-gatherer," the "thunderer," the rain-giver and despotic ruler, gradually he assumed a cosmic significance. Creation, however, was represented as a process of procreation, Zeus being accredited with a huge progeny of gods and goddesses (e.g., Artemis, Apollo, Athena, Ares and Dionysus). It was not until the middle of the 1st millennium B.C. that he was regarded as the primary being and life force from whom all existence emanated. He was conceived pantheistically by Pindar, Simonides and Bacchylides. He was incorporated in the Orphic cosmogony by being said to have swallowed Phanes, the Protogonos born from the world-egg fashioned by Chronos (time), from whom Zeus created all things anew. Finally, in the 3rd century B.C. in the hymn of Cleanthes he became the transcendental creator in whom all things lived and moved and had their being.

**Indian Cosmology.**—Indian religions contain a mass of complex and widely differing ideas. In the Vedic period earth, air and sky were personified as gods generated by a female principle, Aditi, either spontaneously or in conjunction with Daksa, the male principle or creative force. Daksa was also identified with Purusha, the primal man, from whose body the universe was created after he had been sacrificed by the gods. According to the Satapatha Brahmana the universe was shaped like an enormous egg which contained the continents, the oceans, the mountains, the planets, the gods, the demons and humanity, and which was produced in the primeval waters by Prajapati. Similarly, Brahma, the first deity of the Hindu "trinity," the self-created creator of gods and men, deposited in the primeval waters a golden egg, "the egg of Brahma," in which he himself was born again and which he divided into two to fashion the heavens and the earth. In the background of these speculations and traditions is the shadowy figure of the high god, Brahman, and the figures of Vishnu, Shiva and Shakti, whose groups of devotees each maintained the supremacy of its own supreme being, cosmological mythology and cultus. In addition to these cult-gods the Vedic Indra, Varuna and Mitra were assigned universal power in maintaining the universe and the cosmic process.

**Celtic Cosmology.**—Little is known about Celtic cosmological ideas as no creation myths have survived. From references in Irish folk tales, Druidic and Christian traditions, it has been suggested that the sky was thought to have been supported by pillars or by a tree resting upon the earth, which was surrounded with water in the Semitic fashion. Of myths of human origin nothing is known apart from Caesar's statement about an alleged Druidic myth concerning the descent of the Gauls from a chthonian Celtic god (*De bello Gallico* vi, 18).

**CREATIONISM AND TRADUCIANISM**, in Christian theology, are conflicting doctrines regarding the origin of the individual human soul.

Creationism may be defined in the words of Thomas Aquinas as the doctrine "that the intellectual soul is created by God at the end of human generation, and that this soul is at the same time sensitive and nutritive." It can claim the authority of most Eastern Church theologians, of the theological tradition of the middle ages in the west and of John Calvin. Supporters of creationism maintain that it alone is appropriate to the spiritual nature of the soul; for if the soul were transmitted from parents to children as the body is, this would imply that the soul is merely a part or function of man's physical nature. Opponents of creationism argue that it contradicts the statement of Genesis that "on the seventh day God finished his work which he had done"; they urge also that it is inconsistent with the orthodox doctrine that man is conceived and born in original sin.

Traducianism (Lat. *tradux*, "sprout") may be defined in the words of Tertullian as the doctrine that both soul and body "are conceived and formed at exactly the same time, and are born together, and that not a moment's interval occurs in their conception, so that a prior place can be assigned to either." Augustine was inclined to this theory, at least for a time, although finally he was unable to make up his mind either way. Luther also left the question open, but most Lutherans have taught traducianism. Opponents of traducianism find it almost inevitably materialistic, as indeed it was in Tertullian. Modern controversies in both psychology and theology have set the notion of "the total man" in opposition to the traditional idea of a discrete body and soul (see **BODY AND MIND**), and to this extent the conflict between creationism and traducianism has been transcended.

See, for background and history, J. H. Waszink (ed.), *Tertullian De Anima*, pp. 342-348 (1947). (J. J. Pn.)

**CREATIVE EVOLUTION**. The French philosopher Henri Bergson (*q.v.*) in his book *L'Évolution créatrice* (1907; Eng. trans., *Creative Evolution*, 1911) propounded a theory of evolution wholly distinct from the evolutionary hypotheses of earlier thinkers and scientists. Whereas the earlier hypotheses had been determinist (mechanistic or teleological, representing evolution as conditioned either by existing forces or by future aims), Bergson envisaged an evolution in which the free emergence of the individual intelligence could be recognized. He based his theory on the distinction between matter and the *élan vital* or life force, the progress of which he saw as a line continually bifurcating or diverging from its course. The evolution of matter is orderly and geometrical; disorder, with free and unpredictable creativity, is the effect of the life force on its material surroundings. The argument is largely conducted by means of striking metaphor and analogy: life, for instance, is compared to a wave spreading outward toward a circumference which is broken down at one point only; and to an artillery shell from which new shells scatter when it bursts.

**CREATIVITY**. The question concerning the nature of psychic creation is a special aspect of the question of how new forms come into existence in all of nature. Repetition is to be seen everywhere in the natural world, and the perception of one thing as being like another is the basis of ability to avoid unpleasant contingencies and to entertain those that contribute to survival or give pleasure; novelty, from this point of view, offers a threat to our power to anticipate events. Nonetheless, we speak of routine as deadening, and we are happy to think that our day may hold a pleasant surprise; the preacher in Ecclesiastes finds that "What has been is what will be, and what has been done is what will be done; and there is nothing new under the sun," but the thought has little charm for him.

Psychological experiments in the fields of motivation and learning have disclosed the power of novelty as an inducement to action. It has been shown, for example, that primates will learn difficult tasks simply for the reward of being permitted to look out a window or to sit where they can see something happening. Moreover, learning will occur where the reward is stimulation of certain cortical centres by electrical impulses passed into the brain through implanted electrodes. These experiments offer serious challenge to theories that suppose a basic tendency of organisms always to act so as to bring about a condition of psychophysiological equilibrium. They suggest that a more inclusive formulation would posit an essential and continuing tension in higher organisms between, on the one hand, the establishment and maintenance of environmental constancies, inner and outer; and, on the other, the interruption of achieved equilibria in the interest of new possibilities of experience.

The creative process itself embodies this tension, and persons who distinguish themselves in artistic, scientific and entrepreneurial creation exemplify the striving between integration and diffusion, convergence and divergence, thesis and antithesis. Psychological study of highly creative people has led to descriptions of this essential tension in terms of such dualities as intellect and intuition, the conscious and the unconscious, mental health and mental disorder, the conventional and the unconventional, complexity and simplicity.

The counterposing of intuition to intellect by H. Bergson in his theory of creative evolution expresses one of the basic aspects of the tension seen in the creative process. Intellect as Bergson spoke of it is "the geometrizing tendency of mind," finding its purest statement in mathematics, its empirical semimathematical counterpart in science and its everyday form in common sense. Intuition is its opposite; it is nonrational, it "knows" by "feeling," its form of understanding is empathic and immediate rather than analytic and detached. A creative person is usually very intelligent in the ordinary sense of the term and can meet the problems of life as rationally as anyone else can, but he refuses to let intellect rule; he relies strongly on intuition and he respects the irrational in himself and others.

Closely related to Bergson's distinction is Freud's proposed topography of mind, which distinguishes three main systems of mental functioning: unconscious, preconscious and conscious. Conscious thought is largely rational in its operation, and consciousness is both available for criticism and itself the critic. What is unconscious is incorrigible, and an internal censorship bars the way from the unconscious to the preconscious. The ideas in the preconscious, however, are highly motile, can come into contact with one another very rapidly, can readily form a multitude of new combinations and can come to consciousness when they are needed. A certain amount of semantic confusion has resulted from the use of such terms as subconscious and unconscious in theoretical frameworks other than the Freudian, and it is probable that some of the introspective accounts by great innovators and creators in which they speak of influences from the subconscious and the unconscious accord better with the psychoanalytic notion of easy recombinations of ideas in the preconscious.

Whatever the terms used, it seems clear that a creative person is able to find in the developmentally more primitive aspects of his own mental functioning the possibility of new insight that

at first may be only intuitively and dimly apprehended. In brief, he is willing to listen to what is far from the centre of consciousness and rationality in himself; to hold on to his hunches and give them play; to pay attention to vague feelings, which on the grounds of good sense are dismissed by most people, and allow them to have their way with him, even though nothing useful appears to be forming as yet in his conscious mind.

Along with this ability to sustain what may be called preconfigural tensions goes a strong interest in apparent disorder, contradiction and imbalance. Asymmetry and disorder seem to be experienced by creative people as a challenge; by resisting the tendency to reject them prematurely they enrich the world they see, and thus they open the way for an elegant new order more satisfying than the simpler configuration arrived at by omitting contradictory details. Permitting greater complexity leads finally to a grander simplicity, with perplexity a condition to be suffered, or perhaps enjoyed, on the way.

Refusal to be content with the most easily established habits of perception leads creative persons at times to give an impression of psychological imbalance. Indeed, there is reason to believe that many creative persons deliberately invite altered states of consciousness in which the ordinary boundaries of experience are broken. The world may be transcended in mystical states, in feelings of being possessed (as though some higher power were acting through the individual creator), in dreamlike states which bear some resemblance to psychosis and even in psychosis itself. William Blake spoke of a condition in which "the doors of perception are cleansed"; and Aldous Huxley, among others, explored the use of drugs to alter the biochemical factors in personality in the interest of making contact with the primitive substratum of perception which the course of biological adaptation has largely closed. Experimental use, in the study of psychosis, of drugs that produce symptoms resembling those of mental illness has uncovered incidentally some important indications of the way in which psychic regression may contribute to creation and richer integration once mental equilibrium has been re-established.

The question of the relation of mental disturbance to creativity approaches resolution in these observations. Creative persons, far from being psychological cripples or prone to catastrophic breakdown, have exceptionally deep, broad and flexible awareness of themselves. The self is strongest when it can regress (allow primitive fantasies, naïve ideas, tabooed impulses into consciousness and behaviour) and yet return to a high degree of rationality and self-criticism. The creative person is both more primitive and more cultured, more destructive and more constructive, a bit madder and much saner than the average person. In such persons, antinomies find simultaneous expression, leading to resolution and transcendence.

The unconventionality of thought that is found consistently in creative persons is probably in part a resistance to acculturation, which is seen as demanding surrender of one's personal, unique, fundamental nature. This may, although it does not always, result in a rejection of conventional morality, though certainly not in any abatement of the moral attitude.

The psychological conditions that make a society or an epoch creative have been little studied, but it seems likely that social conditions analogous to those seen in individual creativity are important. Freedom of expression and movement, lack of fear of dissent and contradiction, willingness to break with custom, a spirit of play as well as of dedication to work, purpose on a grand scale—these are some of the attributes that a creative society may be expected to have. Creativeness in society is of course a matter of practical concern, since innovation and invention may bring about enormous increases in wealth and power. Man as a species has gained his substantial measure of control over physical forces and over other living things chiefly through his faculties of discrimination, abstraction, adaptiveness through reasoning, and original thought. The importance of originality in human ascendancy can hardly be overestimated.

Particularly among U.S. psychologists, and particularly in the years after World War II when scientific inventiveness became of

wide concern, much research has been carried out on the nature, incidence and cultivation of creativity. Among early workers were H. A. Murray and D. W. Mackinnon, whose joint report to the Office of Strategic Services, *The Assessment of Men*, provided a new emphasis for psychology upon the importance of integrative factors in personality functioning, such as resourcefulness, successful response to challenge and the motivation to do well. D. C. McClelland began his studies on the motive to achieve, in individuals and in nations, and A. Roe used the techniques of clinical psychology to study leading American scientists.

A number of leading psychometricians undertook test-development efforts in the general domain of creative abilities. Important contributions were made by J. P. Guilford and his associates; by J. Flanagan in the measurement of ingenuity; by R. B. Cattell, H. G. Gough and F. Barron in the measurement of personality traits relevant to creative achievement; by J. Getzels and P. Torrance in the study of creativity in schoolchildren and the effect of the educational system upon the development of potential creativity; by M. Stein in the appraisal of creativity in industrial scientists; and by J. Holland, C. Taylor and J. McPherson in the development of rating instruments to establish valid criteria of original performance. The National Science Foundation of the United States in 1955, 1957, 1959 and 1961 sponsored conferences addressed to the general problem of "The Early Identification of Scientific Talent," which brought together at the University of Utah, Salt Lake City, the psychologists most active in prosecuting research on the topic. The published conference proceedings constituted the most detailed statement of the results of thought and research in the psychology of scientific creativity.

**CRÉBILLON** (properly CRAIS-BILLON), **PROSPER JO-LYOT**, SIEUR DE (1674-1762), French tragic poet whose reputation rivaled that of Voltaire, was born at Dijon on Feb. 13 1674. His literary career began in 1705 with *Idoménée*, which was followed by *Atrée et Thyeste* (1707), *Electre* (1708) and *Rhadamiste et Zénobie* (1711). This group of plays established their authors' reputation, and although they were followed by two failures, *Xerxès* (1714) and *Sémiramis* (1717), he remained pre-eminent among French writers of tragedy until he was challenged by Voltaire. After several years retirement, Crébillon returned to the stage with *Pyrrhus* (1726), and wrote *Catalina* (1748) and *Le Triumvirat* (1754).

Voltaire borrowed the subjects of five of Crébillon's tragedies and published a critical *Éloge de Crébillon* in the year of his rival's death. *Rhadamiste et Zénobie*, considered by contemporaries one of the outstanding tragedies of the period, well illustrates Crébillon's characteristic formula: the evocation of horror, coupled with a superficial appeal to the spectator's sensibility by such devices as mistaken identity and complicated relationships, leading to a recognition scene. His was a thoroughly romanesque kind of tragedy, often verging on melodrama.

After the early death of his wife, and his financial ruin some years later, Crébillon became oppressed with an antisocial melancholy, and lived for a time an irregular, solitary life surrounded by birds and animals that he had befriended. However, in 1735 he was elected to the Académie Française; in 1735 he became royal censor; and in 1745 Mme de Pompadour obtained for him

a pension and a post in the royal library. He died in Paris on June 17, 1762.

**CLAUDE PROSPER JOLYOT DE CRÉBILLON** (1707–1777), the only surviving son of the above, whose novels depict 18th-century high society, was born in Paris on Feb. 14, 1707, and lived there all his life except for two periods of exile in the provinces which he earned by satirical allusions in his novels. Of completely different temperament from his father, he wrote lighthearted, licentious novels.

The best known are *L'Écumoire* (1734), *Le Sopha, conte moral* (1742, Eng. trans. by B. Dobrée, 1951)—the morality does not extend beyond the title—and *Les Amours de Zéokimisu* (1746). They were appreciated by Sterne, who saw in his writing some of his own inconsequential narrative style. With his friends and brother dramatists, Alexis Piron and Charles Collé, he founded in 1752 the gay society which met to dine regularly at the "Caveau," and he enjoyed a reputation as a wit and storyteller. In 1748 he married Lady Henrietta Maria Stafford. Like his father he enjoyed the patronage of Mme de Pompadour. He died in Paris on April 12, 1777.

**CRÉCY, BATTLE OF.** On Aug. 26, 1346, an English army under Edward III routed the forces of Philip VI of France near the village of Crécy-en-Ponthieu in northern France. After leaving St. Vaast-La Hougue in the Cotentin on July 18, Edward pillaged lower Normandy unopposed, but by the time he reached the Seine, Philip VI had gathered an army. Edward crossed the Seine at Poissy on Aug. 16 and moved quickly north to the Somme, which was forded below Abbeville on Aug. 24. With an unimpeded line of withdrawal to Flanders, Edward now felt ready to risk a battle with the French, who had pursued him for more than a week.

On the morning of Aug. 26 Edward arrayed his army in a defensive position on the forward slope of the downland between Crécy and Wadicourt; it faced southeast across a small valley. Edward seems to have had at most 14,000 soldiers; about 4,000 were men-at-arms and the remainder mainly archers. They were placed in three divisions; on the right was that of the young prince of Wales (the Black Prince), the earls of Arundel and Northampton commanded the left, and the king's division was held in reserve. Dismounted men-at-arms formed the centre of each division in the front line; and on the flanks, set forward at an angle, were the archers. French scouts located the English during the afternoon, and Philip ordered his van to halt while the troops behind came up and a plan of attack was devised. The French greatly outnumbered the English; according to eye-witnesses, the French had 12,000 men-at-arms and thousands of other troops. Philip could not control the impatience of his men, and toward evening the first of a series of disorganized assaults on the English line began.

Committed to action against his better judgment, Philip ordered the Genoese crossbowmen to advance, while a line of men-at-arms deployed behind them; the rest of the army was still marching in an irregular column along the road from Abbeville. After a brief delay caused by a sudden thunderstorm, the archers and crossbowmen opened the battle. Driven back by the fire of the longbows, the outranged and outmatched crossbowmen obstructed the advance of the cavalry. The French knights charged into the fugitives, and the first two lines degenerated into a mob of struggling horse and footmen while the English archers fired repeatedly at the helpless target. Meanwhile, a fresh body of French knights had arrived, and they staged a second attack. It was similarly repulsed, although a few small parties managed to reach the English lines.

Although they fought bravely, the French never recovered from

this chaotic start, and the battle became one long series of desperate but poorly conducted charges, a fresh onslaught being made as each new corps of troops appeared on the scene. The English archers on the flanks of the two first-line battles had been wheeled up, and the centres of dismounted men-at-arms held back, so that the whole line resembled a harrow with three points formed by the archers. Each successive body of French sought to come to close quarters with the men-at-arms, thus exposing themselves at short range to the arrows on either flank. The English men-at-arms stood firm, while the archers wrought havoc with their cross fire. Fighting continued well into the night, and when the French finally withdrew, their losses had been heavy. In the morning the bodies of more than 1,500 knights and esquires were found on the battlefield, as well as those of many others. Reinforcements which arrived too late for the battle also suffered badly. English losses appear to have been very small.

From Crécy the English moved to Calais, to which they laid siege on Sept. 4. The victory did not greatly further English hopes of conquest, but it seriously impaired French morale. It confirmed in France what had lately been shown at Halidon Hill against the Scots: the tactical value of combining dismounted men-at-arms with archers. See HUNDRED YEARS' WAR.

**CREDENCE** (CREDENCE TABLE), originally a small side table placed near the high table, in royal or noble houses, for the tasting of food and drink for poisons by an official of the household. The name (Ital. *credenza*, Fr. *crédence*) survived after the disuse of this precautionary ceremony, and the table developed into the buffet.

In the Roman Catholic Church the credence table is a small table of wood or stone, placed near the wall on the south side of the altar, to hold the cruets containing the wine and water, the chalice, acolytes' candlesticks and other objects to be used in the Mass. The use of the credence also has been revived in the Anglican Church and pronounced legal.

**CREDI, LORENZO DI** (1457–1537), Italian artist, whose surname was Barducci, was born at Florence. He was the least gifted of three artists who began life as journeymen with Andrea del Verrocchio. The other two were Leonardo da Vinci and Perugino, of whom he was the companion and friend. Credi had a respectable local practice at Florence. He was consulted on most occasions when the opinion of his profession was required on public grounds, e.g., in 1491 as to the fronting, and in 1498 as to the lantern of the Florentine cathedral, in 1504 as to the place due to Michelangelo's "David." At rare intervals he produced large ecclesiastical pictures. The greater part of his time was spent on easel pieces, upon which he expended minute and patient labour. But he worked with such industry that numbers of his Madonnas exist in galleries throughout the world. A fine example of his easel roundels is in the gallery of Mainz. In his old age he withdrew on an annuity into the hospital of Santa Maria Nuova, where he died on Jan. 12, 1537. The National gallery, London, has two pictures of the Virgin and Child, and a portrait of Costanza de' Medici by Credi.

**CREDIT** refers to a transaction between two parties in which one (the creditor, or lender) supplies actual resources—goods, services, securities, or money—in return for a promised future payment by the other (the debtor, or borrower). Strictly speaking, even a child's consent to "behave now" in return for a promise of "candy later" might be viewed as a form of credit. In actual usage, of course, the reference is primarily to money dealings. Business firms, consumers, and governments borrow to obtain money today, offering in return a promise to repay the amount borrowed (the principal) plus an extra amount (the interest; *q.v.*) over a specified future period. Most frequently, interest is payable at semiannual or shorter intervals, and the principal as a lump sum at some future date; but many other arrangements exist.

By definition, credit and debt are created and destroyed simultaneously; *i.e.*, the granting of credit by one party necessarily

implies the assumption of a debt by another, and repayment of the debt extinguishes the credit.

As in any voluntary exchange, a credit transaction benefits both transactors. The borrower may use the proceeds to buy a consumer good or service, thereby availing himself of the enjoyment of, say, a car or a vacation sooner than he would otherwise have been able to. A business firm may borrow to put the loan proceeds to work in income-producing assets such as raw materials, inventories, machinery, or securities, which are expected to earn, in due course, more than the amount borrowed. The lender, in turn, receives the interest (usually expressed as a percentage per annum) as remuneration for his expenses and for bearing the risk that unforeseen developments may cause payment of principal or interest, or both, to be delayed or defaulted.

Because of the time interval which it is the function of credit to bridge, a stable environment, free of major disturbance, is vital if credit arrangements are to flourish. Political, social, economic, or legal upheavals may impair the ability of debtors to repay, devalue or inflate the monetary unit in which credit contracts are denominated, or diminish the enforceability of the contracts—thus undermining the confidence that lenders and borrowers need if they are to enter on commitments spanning an imperfectly foreseeable future.

Credit can be and often is extended directly to the borrower by the accumulator of surplus funds. This can occur face-to-face (e.g., between brothers) or, in societies with developed security markets, through the purchase of debt securities (*see below*), where the issuer of the obligations undertakes to pay principal and interest according to conditions stipulated in the security and related agreements. Most modern credit is, however, extended indirectly, through the intermediation of financial institutions, which are agencies specializing in credit practice. Except for moneylenders, commercial banks are the oldest and most important of such institutions—but they are far from being the only ones. Building and loan associations and life insurance companies, for example, are to be found in virtually all industrial nations. In the United States, savings banks, pension funds, and business and consumer finance companies are among the most important, in addition to those already named. All these institutions borrow funds from the public, in the form of deposits and other obligations repayable on specified terms, for the purpose of relending at a profit. Small amounts are thus amalgamated into large ones, then deployed by institutions possessing specialized lending skills to a diversity of creditworthy borrowers. The original saver is spared the effort of finding, and especially the risk of lending to, the ultimate borrower.

**History.**—The use of credit, in the broad sense of an exchange of current for future resources, is probably as old as organized society. Investigation of primitive cultures and of the records of ancient civilizations reveals numerous arrangements performing the function of credit, mainly through formalized reciprocal gift-giving or redistribution of material possessions through central authorities.

Credit in the commercial, pecuniary sense, however, presupposes an economy in which money plays a significant role. The existence of money makes it possible for accumulated wealth in any form to be transformed into generalized purchasing power that can be lent to others, and to specify terms of repayment that are independent of the activity being financed. More specifically, the origin of modern forms of credit is closely linked to the financing of trade, in which a long time elapses between production and ultimate sale of the commodities involved; moreover, the producer of the goods, the merchant, and the shipper are likely to be different persons or business entities. Credit is needed to pay the producers in advance of the ultimate sale of the product abroad; and money is needed to serve as means of payment among the separate interests.

In finance as in other aspects of Western civilization, many modern institutions were already well known in ancient Greece. Specialized private manufacture and trade flourished, and with them the necessary financial counterparts, including commercial banks accepting deposits, transacting a checking account busi-

ness, and extending credit in various forms. Refined codes of law governed such transactions. These institutions spread throughout the Hellenistic world (and often came to function more as instruments of the state than as agencies of commerce). Greek and allied financial practices were adopted by Rome, where the business of finance and speculation assumed an important part in city life. Credit actively promoted not only domestic agriculture and industry as well as foreign trade, but also military campaigns of Rome, the spoils of conquest serving as the financial base for further expansion.

With the collapse of the Roman Empire, conditions ceased to favour credit use. Nevertheless, such was the urgency and profitability of trade during the Middle Ages that, in spite of disdain for commercial pursuits, religious prohibition of interest and restrictions on the transfer of much real and other property that might have served as collateral, credit use gradually revived. Although credit contracts were generally disguised as partnerships or foreign-exchange transactions to avoid the stigma of usury, a body of law and accounting evolved under which such contracts could be enforced, sometimes even in distant jurisdictions.

The later Middle Ages witnessed the origins of European deposit banking (although the practice did not really take root until the 16th century). Also becoming prominent was the use of the bill of exchange (*q.v.*), which was essentially a binding order, written by one party to a transaction, requiring another party—possibly a foreign branch or representative—to make payment to the bearer of the order under stipulated conditions. In the 17th century the bill of exchange became negotiable, i.e., salable from person to person, and came to serve as the prototype for many later and present-day checks (cheques) and credit instruments.

The major form of credit during these times was the borrowing by kings and nobles to finance their courts and military campaigns. It was these authorities, after all, who provided the protection and law enforcement that enabled trade and moneylending (*q.v.*) activities to be carried on; participants in these ventures therefore often had little choice but to provide credit when governments demanded it. Sometimes special privileges or the right to receive or collect certain tax revenues were granted in return. Although repayment was uncertain—often the debts were merely refinanced as they fell due (as is done also by modern governments)—major lenders were not always defenseless: in some cases they were able to go so far as to prohibit the delinquent noble from leaving his castle until he made payment. The practice, already well established in antiquity, by which borrowers could mortgage their persons as collateral for loans and be condemned to peonage or jail if they defaulted, was common in medieval times (and continued late into the 19th century). On the whole, however, the restrictive practices of the guilds—they prevented the growth of competitive large-scale enterprises producing for the market, upholding instead the practice of making to order—and the generally local nature of production and distribution, together with the strictures of the Church against the charging of interest, militated against widespread development of credit during the Middle Ages.

The great proliferation of credit and credit types characteristic of modern industrial life is associated with the Industrial Revolution and subsequent technological change. The building of factories containing quantities of expensive equipment required larger concentrations of capital than individuals were able to accumulate by themselves. Moreover, the increasing orientation of trade toward far-flung, competitive markets greatly increased the amount of working capital needed to bridge the time gaps between expenditures for raw material, manufacture, shipment of the product to distant markets and its storage there, and receipt of the ultimate sale proceeds. At the same time, however, the whole process, once completed, was generally highly profitable; and this provided the incentive to borrow the funds, the wherewithal to pay interest, and an attractive and reasonably safe return to the lender. The more complex and roundabout the technology of production, distribution, and consumption has become, the greater have grown the opportunities for the employment of credit.

**Kinds of Credit.**—The kinds of credit found in various parts of the world, adapted to particular local customs and laws, and differing as to purpose, duration, and security, are far too numerous to name here. In every loan, however, whether made by a major financial institution staffed by specialized lending experts or by friend to friend, the lender must evaluate certain basic factors, sometimes called the "three C's" of credit: the applicant's character, capacity, and collateral. As for character, an earnest intention to repay even in adverse circumstances is essential, since the costs of recovering from a recalcitrant borrower can easily consume the revenue the lender may earn. The lender must also judge whether the borrower will in fact have the capacity to repay on schedule; often the lender may have more experience and expertise in evaluating the profitability of a project than the borrower who wishes to undertake it. Finally, the lender must determine what provisions he will require in the credit agreement to protect him if matters go awry. This may be provided by a pledge of specific security—as in a house mortgage, where the lender takes possession in case of default. (The trend has been toward imposing more general rather than specific claims on the debtor's resources and, where appropriate, including in the loan agreement provisions intended to prevent the borrower from conducting his finances in ways that might jeopardize repayment of the loan.) Having weighed these considerations, the lender must then decide whether the return from the loan offers adequate compensation for the risk of nonpayment and for the expenses. When the lender is a financial institution, these expenses may prominently include the interest the lender himself must pay to attract funds. Some lenders are willing to accept greater risks than others, but naturally they charge a higher rate of interest.

In credit, as in other aspects of a monetary economy, specialized instruments and institutions have developed to meet specialized needs. The most common kind of loan, perhaps, is the short-term, seasonal loan. It originally developed in agriculture, the farmer borrowing to finance his planting or to meet his consumer needs during the interval between planting and harvest, and the harvest yielding the proceeds to pay off the loan. Such "seed" loans were known in ancient Babylonia, and are made today wherever farming is practised. Loans to business firms to finance short intervals between production and sales, particularly where the supply of raw materials or demand for the product is seasonal in nature, follow the same pattern. The principle is readily extended to include any so-called short-term self-liquidating loan, in which credit is used to finance the purchase and the working of raw materials that are quickly converted into the final product and rapidly sold, the proceeds being used to terminate the loan. In the 19th century and to some extent in the early 20th century, important schools of American and British financial thought held that this was the only kind of loan commercial banks should make if financial crises were to be avoided; but it is doubtful whether this "real bills" doctrine was ever wholly followed in practice, and it was subsequently abandoned. It has become standard bank practice to frequently renew short-term loans (although an occasional "clean-up" may be required) and indeed to make longer-term business loans to finance permanent additions to fixed and working capital.

Another major kind of credit is the mortgage (*q.v.*), a device which can be traced back in Western societies at least to ancient Athens. This is a loan, normally for a term of several years, extended against the collateral in the form of land or buildings that pass to the lender in the event of default. Until comparatively recent times, mortgages were made primarily on the strength of the income yielded by the farmland, factory, rental housing, or stores involved—the income out of which the interest payments were met. Since the development of urban and suburban individual home-ownership in industrial countries, a large volume of mortgages has been extended by savings institutions on the basis of the home-buyer's income, although this in no way derives from the house. Since the 1930s these loans have generally been amortized; i.e., the principal is gradually repaid along with the interest payments, so that by maturity the principal of the debt has been largely or entirely extinguished.

Accompanying greater and more widely shared affluence, other forms of lending to consumers burgeoned in the U.S. in the 1920s and gained major importance there and elsewhere in the 1950s and after. Consumer credit, particularly installment credit (*q.v.*), like the home mortgage, is now generally amortized over its life-span. At first it was extended mainly for the purchase of private automobiles, household refrigerators, and the like, with the goods serving as collateral. (In the United States and Canada the consumer takes actual title to his purchase immediately; in the United Kingdom, many transactions take the form of hire-purchase agreements, in which full title does not pass until periodic payments have been completed.) Later, the scope of consumer credit was extended to a multitude of other purposes, including the purchase of such "perishables" as vacations; and—in keeping with the general trend in credit practice—the total earning power of the borrower has come to serve as the real security for the loan. In the U.S. and the U.K., charge accounts and the "credit cards" issued by stores, other business firms, and banks are in common use; these enable the holder to make a large variety of purchases for deferred payment.

Economic entities of more than ordinary size and repute can borrow through the sale of debt securities on the open market. These securities are most commonly called bonds (*q.v.*) or notes in the U.S. and loan stock in the U.K. (In the U.S., "stock" refers exclusively to equity shares which give the holder the status of owner rather than creditor.) In principle, these debt obligations are identical to loans. They afford the issuer the opportunity to draw credit from many lenders at the same time and on an impersonal basis. The buyer gains the convenience of lending in whatever amounts he chooses, as well as the option of selling the security in the market if he wishes to retrieve his money before the due date. Issuance of these instruments is a principal form of long-term borrowing by central and local governments and large business corporations; life insurance companies, pension funds, banks, and wealthy persons are the main buyers (creditors).

Governments, financial institutions and securities dealers, and certain well-established business firms can also borrow at short term, ranging from a day onward, in the money market (*q.v.*), where banks, businesses, and others make available their temporary excess funds. Astounding volumes of such debt remain outstanding, although the turnover is rapid and the list of lenders is constantly changing. Only very large amounts can be handled in the money market, if the interest earned by the lender over short intervals is to exceed the expenses of processing the loan.

**Credit and the Economy.**—The cost and the terms on which credit is available influence the extent and kinds of credit-dependent business activity. Since the amount of credit that can be created depends on the surpluses that members of the economy save out of current income, wealthy countries generate more credit per capita than do poor ones. Also important are the attitudes of governments, businesses, and the public toward saving and credit use—attitudes in turn conditioned partly by confidence in the sustained purchasing power of the monetary unit which serves as the unit of account and in the reliable enforcement of official and private contracts.

Short-run fluctuations in credit availability are related to the business cycle (*q.v.*). Boom conditions tend to be associated with large credit demands for business expansion and a general tendency toward more spending. Even though the volume of outstanding credit may be growing rapidly during a boom, credit then becomes "tight," since the quantity demanded tends to outrun the proffered supply. During a recession the converse occurs, and the availability of credit eventually eases unless (as in the Depression of the 1930s) lenders remain so fearful for the safety of their capital that they draw back from assuming the inevitable modicum of risk.

Credit developments, particularly overinflation followed by failure of businesses and financial institutions, are often cited as disturbing or destabilizing employment and price levels. Such effects occur primarily because credit and monetary creation generally go hand in hand. The spread of industry and credit depends, it may be repeated, on the existence of a generalized unit of purchasing

power—money—that enables surpluses earned in one sector of the economy to be transferred to another. A loan of grain would not be particularly useful to an industrialist; however, a loan of money (received from the sale of grain) enables him to bid in the market for the labour and materials he desires. In the Western world the role of money was at first performed mainly by gold and other precious metal coinage, but over the centuries the role of metal as means of payment has been gradually supplemented, if not supplanted, by commercial-bank deposits subject to transfer by check. Commercial banks have therefore been able to extend and increase credit by, in effect, opening for the borrower newly created checking deposits. New credit of this kind, as well as new credit derivable from a more active use of their balances by deposit owners for lending purposes ("disharding" or increases in the "velocity" of deposits), expands the credit supply beyond what normally would be available. The potentialities for overexpansion are great, and have led to credit "bubbles" and "panics," in which the slowing or stoppage of a rapid rate of credit expansion has (among other consequences) uncovered many unsound loans and led to financial or business collapses or both. As this description of overinflation indicates, however, the root causes of these unwanted events have been monetary, the credit aspect of the overinflation being only one of several symptoms of monetary malaise.

Boom-and-bust experiences have led, virtually around the globe, to the development of official central banks (*q.v.*)—in the U.S. the Federal Reserve System, in the U.K. the Bank of England—with powers to regulate the extent of deposit and money creation. The central banks are not motivated by considerations of profit or loss, but rather work to achieve overall economic goals set by national policy. Central banking policy is properly referred to as monetary policy, of which credit policy is one important aspect. A much oversimplified description of monetary policy, but adequate for the present purpose, is that it determines the rate of money creation. In the given economic environment this will result in a certain level of interest rates. (Alternatively, the central bank may select the level of interest rates, which will give rise to a particular rate of money growth.) In turn, the rate of monetary growth and the level and movement of interest rates largely determine short-range fluctuations in general credit availability. From this point of view the proper rate of money and credit expansion is that which promotes full but noninflationary growth and employment of labour and industrial capacity. Too much credit may produce inflation; too little credit may produce depression.

Within a given credit aggregate, selective measures may be employed to prevent credit abuses or to channel the credit flow to particular sectors of the economy. For example, consumer or mortgage credit may be regulated by establishing and varying the requirements for the size of minimum down payments and maximum maturities. Credit for securities purchase or other purposes can be regulated by requiring certain amounts or kinds of collateral. Credit to promote exports is frequently subsidized to help bolster national gold and foreign-exchange holdings. In general, regulation may run the gamut from "guidelines," which lenders are expected to follow voluntarily, to broad legal requirements and safeguards prescribing general lending policy, to detailed official supervision and determination of individual credit agreements. Discriminatory tax incentives and penalties for particular classes of lenders, kinds of credit, and interest income can accomplish the same purpose. The usefulness of selective credit controls is that they can bend the financial mechanism to serve politically established national objectives. The disadvantage of selective credit controls appears when these national objectives conflict with what the market would determine; selective credit controls may then be expensive and difficult to enforce and may produce harmful and inequitable side effects and waste in related but unregulated markets.

**Summary.**—Every economy characterized by specialization and interdependence in labour and industry—be it primitive, capitalist, or communist—depends on a mechanism for the transfer of unused purchasing power accumulated in some parts of the

economy to other parts where that purchasing power may be more useful. This is particularly true of modern industrial economies, which depend on heavy capital investment and large markets for exploitation of the efficiencies of large-scale production. In such economies, moreover, most income takes the form of wages and salaries. The chief recipients of income, therefore, are households, few of which undertake business capital investment. Even purchases of "consumer" capital goods, such as homes, cars, and appliances, often cannot be financed out of current income by the households concerned, and the funds must be borrowed, usually through the services of financial intermediary institutions, from other households that are in financial surplus.

Thus the institution of credit serves to transfer the financial surplus of savers to those who are eager and able to put this purchasing power to use. In the absence of such a mechanism the material resources at the command of this purchasing power might remain unemployed and go to waste. The surplus is lent to those borrowers offering the best return, after taking account of all dimensions of the credit contract, including rate of interest, risk and pertinent tax and other official regulations.

The volume of flow of credit depends primarily on the level of income, the proportion of income that is surplus, and the willingness of the savers to lend the surplus. Short-run fluctuations in the credit and debt expansion occur in response to the business cycle and to the actions of the authorities controlling the rate of monetary growth. Since in modern economies small differences in unemployment, price level, foreign-exchange rates, or growth rate of real output may spell the difference between politically acceptable or unacceptable performance, modest fluctuations in credit flow can have large consequences.

**CRÉDIT FONCIER DE FRANCE**, a limited company under the supervision of the ministry of finance. It is managed by a governor, assisted by two deputy governors, who are appointed by an order in council (*décret présidentiel*). Founded by a decree of Louis Napoléon in Feb. 1852 under the name of the Banque Foncière de Paris, the Crédit Foncier de France was sanctioned by a decree issued in March 1852 and in December of the same year received authority to act under its present name.

The company was originally set up with the object of granting to owners of urban or rural properties long-term loans on mortgages to be paid off by annual installments, but its activities were gradually extended. Thus it was authorized in 1854 to grant short-term loans without amortization; in 1860, to discount bills from the *Sous-Comptoir des Entrepreneurs* issued particularly against the representation of credits granted with a view to building; and in 1860 and 1862, to grant loans, even without a mortgage appropriation, to *départements*, communes, owners' trade associations and public bodies. Then, after various decrees, the Crédit Foncier successively extended its activities to Algeria, Tunisia, Morocco and, generally speaking, to the French colonies, protectorates and territories under French mandate. Finally, in 1928, it was authorized to grant loans on mortgage to owners of seagoing or inland navigation vessels.

The Crédit Foncier de France raises the funds necessary for carrying out these transactions by issuing bonds which, like the loans, are of three kinds: land, communal or maritime. The first are specially "pledged" as security by the mortgage claims of the company, the second by the debts owed by the *départements*, communes and public bodies, and the third by the maritime mort-

gage loans. The amount of bonds issued cannot exceed that of the borrowers' receipts; thus the bonds in circulation are always pledged against at least an equal amount of claims. Furthermore, the bonds have a common guarantee in the registered capital and the whole of the company's reserves.

After World War II, the help of the *Crédit Foncier de France*, jointly with that of the *Sous-Comptoir des Entrepreneurs*, was specially enlisted in connection with the solution of housing problems. It was given the task of managing the *Fonds National d'Amélioration de l'Habitat* (National Fund for the Improvement of Housing) created in Oct. 1945, and a convention with the state (Oct. 1950) entitled it to grant specially favourable loans to owners whose residential buildings were destroyed during the war.

The *Crédit Foncier de France* and the *Sous-Comptoir des Entrepreneurs* are able to offer credits or special loans to people wanting to build houses, who have been granted by the state building subsidies convertible into bonus interests. These credits or loans are granted directly by the *Crédit Foncier* if the borrower does not need the funds until the building is completed, or, more generally, by the *Sous-Comptoir* if the funds are required while the construction is in progress. These credits are, as a rule, granted for a maximum period of five years, but in most cases, the borrowers are not able to pay back within such a short period; they can then be given, upon request, the assurance that these credits will be replaced, upon expiration, by redeemable long-term loans. The *Crédit Foncier* insures the financial service of the building subsidies allocated by the state, which are set against the loan charges and thus act as bonus interests. Lastly, the *Crédit Foncier* accepts discount for the credit operations presented to it by the banks relating to the erection of residential buildings, to the repair and equipment of commercial buildings, to the erection and maintenance of buildings for agricultural development and to the mobilization of stock issued by the *Caisse Autonome de la Reconstruction* (Autonomous Fund for Reconstruction). (P. Vr.)

**CREDIT INSURANCE.** This type of insurance affords indemnity to merchants and manufacturers against the risk of loss resulting from insolvency or protracted default of customers to whom goods are sold on credit. Applied to export credits, the term may embrace facilities which lie outside normal insurance underwriting.

Plans to cover credit risks existed in continental countries during the second half of the 19th century, and in England and the U.S. during the last two decades of the century. The business generally proved expensive to operate and early progress was slow. In its modern technique, credit insurance in England dates from the close of World War I. The depredations of war opened up a vast export field. In consequence, there came into being two credit insurance organizations, the Trade Indemnity company and the export credits department, representing private and state enterprise respectively. At first interested only in bills of exchange, the export credits department extended its activities in 1926 to the guarantee of export credit risks and, in 1931, the department was rationalized on a semicommercial basis and the word "guarantee" incorporated in the title. The service provided by these two organizations in the field of export credits then proceeded on similar lines until 1933, when economic difficulties in many countries brought into play factors which were to have a marked effect on the development of credit insurance in Great Britain. With exchange control on a national basis, additional insurance cover was sought against nonpayment of a debt as a result of transfer restrictions imposed by foreign governments, a form of political risk which it was considered the government organization was in a better position to assess and underwrite than was a private insurance company. Thus occurred a cleavage in underwriting interests which still obtains.

Subsequent development was along two clearly defined paths: the export credits guarantee department, concerned only with export trade; and the Trade Indemnity company, supported by a consortium of insurance companies as shareholders and reinsurers, concerned mainly with home trade. Risks inherent in the imposition of currency transfer restrictions, the cancellation of import li-

cences and political risks such as war or revolution cannot lightly be ignored by exporters and, since the government organization is not disposed to cover extraneous and political risks without the normally insurable commercial risk, it is understandable that by far the larger volume of export credits insurance is government subscribed. The private company has a monopoly of the equally wide field of domestic credit, scope in the field of export credits to countries with no pronounced political risk involved and insurance of certain purely foreign business.

World War I crystallized the need for credit insurance in the countries of western Europe. In general, credit insurance in international trade developed on the basis of co-operation between state and private enterprise, and undertakings specializing in credit insurance appeared in all the more important commercial countries of the world. The effective supervision of credit risks on an international basis requires collaboration with credit insurance companies and state organizations operating in the countries concerned, and this is achieved through the International Credit Insurance association of Zürich, founded in 1928, and the Union d'Assurance pour le Contrôle des Crédits Internationaux of Bern, established in 1934.

The years of greatest expansion in credit insurance followed World War II. As the business expanded the coverage was broadened. It is possible for specific accounts or sections of accounts only to be insured, but it is more usual, both in home and export trade, for a firm to insure all credit sales except those where no commercial risk exists; e.g., when the buyer is an associated company or an official body. The insured is expected to retain a financial interest in the insured transaction, and it is usual in the home trade for the insurance payment to be 75%-85% of losses incurred.

Claims are paid within 30 days of the insured debt being admitted to rank against the insolvent estate or, in the case of "protracted default," within six months thereafter.

The standard facilities of the government organization include short-term contracts and shipments policies, external trade policies, dollar-market and medium-term policies. There are, in addition, policies devised to meet specialized needs. The exporter is required to exercise customary business prudence and to retain some reasonable interest in the transaction. For this reason the extent of the cover is normally 85% of loss through the insolvency of, or protracted delay in payment by, the buyer, 90% of loss arising from any other cause covered by the policy and arising before shipment and 95% of such loss where the cause arises after shipment. Repudiation of a contract or a debt is not in itself adequate grounds for a claim. (P. Ss.)

**Credit Insurance in the United States.**—Credit insurance in the United States originated as a result of legislation enacted in 1885 and 1886 in New York, New Jersey and Louisiana which authorized the incorporation of companies to write this form of insurance. In 1887 the American Credit Indemnity Company of Louisiana was organized and, in 1888, the U.S. Credit System company was established in Newark, N.J. Neither of these companies enjoyed success and soon withdrew from the field. In 1891 the American Credit Indemnity companies of New Orleans, of St. Paul and of Minneapolis, respectively, were established, but the efforts of these companies were also unsuccessful and they ceased to operate after 1894.

In 1892 the London Guarantee and Accident company of London, Eng., created a credit insurance department in the United States, and in 1893 the American Credit Indemnity Company of New York was founded. Both of these companies survived and wrote credit insurance successfully and uninterruptedly; in the latter 1950s they were the only two in the United States engaged in writing such insurance. Other companies entered the business after these two but all eventually discontinued the writing of credit insurance.

Original credit insurance policies required the insured to sustain an agreed percentage of loss on gross annual sales before the insurer was liable. This percentage, based on the applicant's previous credit loss experience, was termed initial or own loss. The policy was issued in a face amount double the largest individual

debtor's limit, and it agreed to pay losses, subject to these limits, in excess of the amount of the initial loss. Amounts of insurance on individual debtors were based on ratings of a mercantile agency selected by the insured when application was made for the policy. The meaning of insolvency was confined to that arising from bankruptcies, receiverships, absconding debtors with no assets or a judgment that the debtor was unable to pay in full. Later the more comprehensive form of policy evolved.

Credit insurance adheres to the principle that it is not designed to cover the insured for losses which can be foreseen or which result from the insured's carelessness. In an effort to apply this principle, the modern policy provides that there will be no coverage for normal bad debt losses inherent in the insured's line of business. This normal loss, often referred to as a primary loss, is fixed by loss experience statistics. It is designated in the policy as a fixed percentage, subject to a minimum amount expressed in dollars. The insurer also uses a so-called coinsurance provision. This is not similar in application to the fire insurance coinsurance clause, but is actually an application of the deductible average principle used in marine insurance. Under the credit insurance coinsurance provision the insured bears an actual percentage of each loss—such as 10% or 20%.

The modern credit insurance policy is designed to protect wholesalers, jobbers and manufacturers against abnormal credit losses resulting from the insolvency or protracted default of a customer to whom goods have been sold on credit. It tends to improve the credit standing of the insured, and through the collection services of the insurer the losses on delinquent accounts may be reduced. There are about nine different forms of policies available and these, in turn, may be divided into two major groups, known as back coverage policies and forward coverage policies. In back coverage policies the insurance company agrees to reimburse the insured for losses occurring during the policy term and, through the use of a back sales rider, covers unpaid accounts receivable in good standing on the insured's books on the day the policy becomes effective. Unless this policy is renewed, the coverage ceases at the end of the policy term. In forward coverage policies the insurance attaches to sales, shipments and deliveries of merchandise made within the shipment period of the policy. Inasmuch as it covers only those transactions made during the policy term, no back sales rider is attached. When this policy expires, the coverage provides for the filing of claims up to 90 days, plus the longest terms of sale after the last day of the shipment period subject to an over-all limit of 215 days.

Diverse forms are issued for varying needs but generally "insolvency" includes bankruptcy or insolvency petition, assignment, receivership, compromise, attachment, execution, death or insanity of sole debtor, chattel mortgage, absconding, confession of judgment, transfer or sale of stock in bulk, a debtor's business taken over by a committee. Besides these insolvency definitions, collection policy forms provide for assigning accounts as insolvent after becoming due and payable under original terms of sale. Under this form accounts can be filed as an insolvency when they become past due on original terms of sale or, at the policyholder's option, within an agreed number of days after original due date.

Original underwriting conditions have greatly improved. Credit insurance companies pooled loss statistics for a period of years, resulting in experience normal loss tables showing average experience on any given sales basis in more than 400 different businesses. The larger proportion of credit insurance policies in the United States cover the policyholder's annual sales volume, but the demand for coverage on individual debtors is met by single credit account policies.

Considerable hazard attends credit insurance underwriting, including regional disasters such as floods and crop failures, future business conditions, reasonable expectancy of business depression in cycles, when credit losses reach large proportions, and the especially important factor of moral hazard, the control of the insured hazard being in the policyholder's hands to a greater extent than in other insurances. It therefore demands of underwriters a broad general knowledge of business and of local conditions, acquaintance with different specific hazards and keen

judgment of human nature obtained only through wide experience over a number of years.

**CRÉDIT MOBILIER OF AMERICA**, a U.S. construction and finance company associated with the building of the Union Pacific railroad, 1865–69. Although its operations were more or less typical of 19th-century railroad building in the U.S., sensational newspaper exposures and congressional investigations in 1872–73 established it as a symbol of post-Civil War corruption. Experience had already taught veteran railroad organizers that more money could be made from construction contracts than from the operation of a completed road. This promised to be doubly true in the case of the Union Pacific, which was supported by federal loans and land grants but proposed to span a vast unpopulated region between the Missouri river and Great Salt Lake. Crédit Mobilier was part of a complex arrangement whereby Thomas Durant, Oakes Ames and other men in control of the Union Pacific railroad contracted with themselves for construction of the railroad. Chartered in 1859 as the Pennsylvania Fiscal agency and taken over by Union Pacific men in 1864, Crédit Mobilier was itself a contractor for only the first 247 mi. of road. Thereafter it functioned as the guarantor of extravagant contracts awarded to Ames and J. W. Davis and assigned by them to seven trustees chosen from the inner circle of Crédit Mobilier and the Union Pacific. The trustees received payments from the Union Pacific (more often in its stock and bonds than in cash), paid the actual costs of construction, and distributed the profits among holders of Crédit Mobilier stock. These arrangements, while facilitating the disposal of Union Pacific securities and speeding completion of the railroad, enabled the men in control to enrich themselves by converting Union Pacific assets and credit into construction profits. In the process, the railroad itself was overcapitalized and impoverished.

Crédit Mobilier became a public scandal when it was revealed that in 1867–68, Oakes Ames, whose financial responsibilities did not prevent his serving as congressman from Massachusetts, had tried to win friends for the company by selling shares of its stock at discount prices to a number of his colleagues. The house of representatives appointed a committee to investigate these transactions, and after hearing its report early in 1873 censured Ames and Rep. James Brooks of New York, but absolved men like Vice-Pres. Schuyler Colfax and Rep. James A. Garfield who had accepted their favours.

See J. B. Crawford, *The Crédit Mobilier of America* (1880), and the studies of the Union Pacific railroad by Henry Kirke White (1895), Nelson Trottman (1923) and Robert W. Fogel (1960). (D. E. F.)

**CREDITON**, a market town and urban district of Devon, Eng., lies 8 mi. N.W. of Exeter partly in the narrow vale of the Creedy near its junction with the Yeo. Pop. (1961) 4,427. Area 1.7 sq.mi. Documents of the 13th century mention an east or old town and a west or new town. Crediton (Kirton) is traditionally the birthplace of St. Boniface (c. 680), patron saint of both Germany and Holland, who was martyred at Dokkum, Friesland in 745. Perhaps in his memory—since the great extent of the parish shows that it was thinly populated—it became in 909 the seat of the first bishopric in Devonshire. It was probably only a village in 1049, when Leofric, then bishop of Crediton, requested Pope Leo IX to transfer the see to Exeter, as Crediton was "an open town and much exposed to the incursions of pirates." The parish church was built (1150) as a collegiate church on the site of the cathedral. The earliest of Crediton's seven charters, now in the Bodleian library, Oxford, is dated 739. The Queen Elizabeth grammar school for boys was founded under the 1547 charter. The wool trade, established by 1249, was at its height in the early 18th century. Agricultural trades with engineering, tin-plating, woodwork and the making of cider and confectionery have superseded the woollen and serge industries. In 1897 Crediton was made the seat of a bishopric suffragan in the diocese of Exeter.

**CREDIT UNION**, an organized group of people who save their money together and make low-cost loans to each other. These are usually short-term consumer loans, mainly for automobiles, household needs, medical debts and emergencies. In some countries where economic development lags, credit-union loans are primarily for farm production and small business enterprise. Each credit union operates under government charter and supervision which limits membership and service to a common-bond group, such as: (1) employees of a business firm or government agency (e.g., municipal employees, teachers); (2) members of an association, lodge or church parish; or (3) residents of a small well-defined community. At annual meetings the members select from their own number the directors, the credit committee and the supervisory committee.

In its broad outline the credit union self-help movement stems from societies founded in the middle 1800s by Friedrich Wilhelm Raiffeisen in Germany and Luigi Luzzatti in Italy, both of whom owed much to the example of the less idealistic Schulze-Delitzsch societies in Germany. The first credit union in the western hemisphere, where the greatest development was to take place, was organized in 1900 at Levis, Que., by Alphonse Desjardins, a legislative reporter whose work revealed the misery caused by usury. Desjardins also helped organize the first U.S. credit union, in Manchester, N.H., in 1909. The same year Massachusetts passed the first state credit union act. It resulted from a study made by Bank Commissioner Pierre Jay and strong legislative-hearing support by Desjardins and Edward A. Filene, a Boston merchant who had been impressed by credit co-operatives he had observed in India, and who foresaw the growing importance of consumer credit. In 1921, to accelerate U.S. credit union growth, Filene set up and financed the Credit Union National Extension bureau. Under Roy F. Bergengren, later assisted by Thomas W. Doig, the bureau provided legislative, organizational and operational services which speeded up the growth of credit unions notably.

In 1934 the Credit Union National association (CUNA), a federation of credit union leagues, was established by the credit unions themselves to take over the work of the bureau. In the same year the U.S. congress passed the Federal Credit Union act which was brought up to date by amendment in 1959. The Mutual Insurance society was formed as a CUNA affiliate in 1935 to provide credit union life insurance services and a second affiliate, CUNA Supply co-operative, was organized in 1936. Within a few years nearly all the states of the United States and all provinces of Canada had special credit union laws. In 1939 CUNA spread its membership to include the western hemisphere, and in 1958 it became a world-wide association. Credit unions made notable progress in Australia and in many countries of Latin America and Africa. In 1954 the CUNA World Extension department was created.

By 1962 there were more than 28,000 credit unions, located mostly in the U.S. and Canada. They had more than 15,000,000 member-owners with \$6,000,000,000 in assets. Their sizes ranged from fewer than 100 members to more than 30,000. The typical credit union had 500 members and \$100,000 in assets.

Stewart, *Credit Unions—Self-Help Family Finance*, Public Affairs Committee (1955); John T. Croteau, *The Federal Credit Union* (1956). (M. F. Gv.; W. P. Lu.)

**CREDO QUIA ABSURDUM**, a current Latin phrase of uncertain provenance, meaning "I believe it because it is absurd." It seems to be derived from a faulty recollection of a passage in Tertullian's *De Carne Christi*, v, in defense of Catholic christology against Marcion's docetism: *Natus est Dei Filius; non pudet, quia pudendum est: et mortuus est Dei Filius; prorsus credibile est, quia ineptum est: et sepultus resurrexit; certum est, quia impossibile* ("The Son of God was born: there is no shame, because it is shameful. And the Son of God died: it is wholly credible, because it is inappropriate. And, buried, He rose again: it is certain, because impossible").

The underlying sentiment is characteristic of fideism (the assertion of Christian faith independent of all rational presupposi-

tions or "preambles"), an attitude which has often been taken by extreme advocates of Augustinian doctrine; cf. in this connection St. Augustine, *Confessions*, vi, 5 (7). It is implicit also in the existentialist philosophies, with their specific confrontation of the absurd (however interpreted).

**CREE**, an Algonkian Indian tribe, or loose aggregation of bands, which formerly held a large territory south of Churchill river and from Hudson bay west into Manitoba and Assiniboia in Canada. The name is an abbreviation from Cristineaux or Kinisteneaux. Essentially a forest people, as shown by the resemblance of their dialect to Ojibwa (q.v.), part of the Cree became bison hunters and have been known as Plains Cree. When the Assiniboin broke away from the Dakota, they moved into Cree territory, with the result that the two groups became allied against the Dakota and Blackfoot, the latter ancient relatives of the Cree. The culture of the Cree is essentially of eastern woodland type, but lacking the maize agriculture which their habitat forbade. During the 1960s there were about 15,000, including those of mixed Cree-European genetic origin. See also ALGONKIAN TRIBES.

(A. L. K.)

**CREECH, THOMAS** (1659–1700), English classical scholar whose principal work, a translation of Lucretius in rhymed heroic couplets, enjoyed considerable popularity in its time. Born at Blandford, Dorsetshire, in 1659, he received his early education from Thomas Curgenvin, master of Sherborne School. In 1675 he entered Wadham College, Oxford, and in 1683 obtained a fellowship at All Souls'. He was headmaster of Sherborne from 1694 to 1696, after which he returned to Oxford. In 1699 he received the college living of Welwyn. He had for some time been suffering from depression, probably as the result of romantic and financial difficulties, and in June 1700, before he had taken possession of the living, he hanged himself.

Creech's translation of Lucretius was highly regarded by his learned contemporaries, and its popular success approached that of Pope's translation of Homer and Dryden's of Virgil. In the view of later generations, however, Creech had failed to capture the vigour of the original; and, although the work was frequently reprinted in the 18th century, it afterward fell into obscurity. Creech also undertook the translation of a number of other Latin writers, including Horace, Ovid, Plutarch, Theocritus, and Juvenal, but in none of these efforts did he achieve much success.

**CREED**, a brief summary, fixed in language and officially authorized by the church, of essential articles of Christian belief. In origin and use creeds belong to the liturgy, and although the desire to refute heresy and safeguard orthodoxy was increasingly present in them their primary motive was to set forth saving truths.

Later ages attributed the first creed to the apostles and identified it with one of the three formularies examined below. It is intrinsically improbable, however, that any creed in the strict sense existed in their day, and a study of the New Testament reinforces this conclusion. Nevertheless the ground was already prepared for the emergence of creeds. From the start the church possessed its distinctive gospel or *kerygma* ("proclamation"), and this had a definite dogmatic outline. As early as the apostolic age it was beginning to crystallize in conventional slogans (e.g., "Jesus is Lord": cf. Rom. x, 9; I Cor. xii, 3), and longer semistereotyped confessions with a credal ring (e.g., I Cor. xv, 3 ff.; Rom. i, 3 ff.). The pattern and content of these latter were determined by the particular situations in the church's life (baptism, Eucharist, catechetical instruction, etc.) which prompted Christians to declare their faith. In the 2nd century, for example, as Irenaeus and Tertullian testify, a loosely worded, flexible epitome of essential doctrine modeled on the trinitarian scheme was in use for catechetical purposes and was known as the "rule of faith."

Creeds proper took their rise, in the 2nd century if not earlier, in the baptismal liturgy, which by its very nature demanded a formal affirmation of faith (cf. Acts viii, 37, not part of the original text but a very early insertion reflecting 2nd-century practice); hence their form, beginning with the words "I believe . . ." (Lat.

*credo*). As the accounts of Justin and Hippolytus suggest, the practice was for the candidate to be asked about his belief in Father, Son and Holy Spirit respectively. The basic pattern was dictated by the Lord's baptismal command (Matt. xxviii. 19), and the three questions were in effect a creed in interrogative form. Their content corresponded closely with the statements about the three persons in the "rule of faith." In the 3rd century the instruction before baptism was greatly elaborated, its final stage consisting in a close study of the creed, and the custom arose of requiring the candidate to rehearse it in a declaratory form to the bishop immediately before the actual baptismal service. Henceforth, while the questions at the moment of baptism continued to have crucial importance, the rite had prefixed to it an affirmative creed of the type familiar today. The name "symbol," applied in the 3rd century to the baptismal questions and answers either because they seemed to symbolize the Triune Godhead or because baptism was regarded as a contract (*symbolum* could mean a contract or pact), was transferred to the declaratory creeds which were thereafter commonly known as symbols. Many baptismal creeds, from east and west, have survived from the early centuries. The western ones, while theological in implication, confine themselves largely to reciting the facts of the *kerygma*, and, for reasons explained below, all belong to one family. Eastern creeds differ widely from each other, and are more obviously theological, stressing, for example, the oneness of God, the Son's precosmic birth and the saving purpose of the incarnation.

With the dawn of the 4th century creeds began to be used as proofs, or alternatively tests, of orthodoxy. At the Council of Nicaea (325), for example, the church historian Eusebius of Caesarea handed in his local creed to clear himself of the charge of heresy; and, much more significantly, the council itself promulgated a creed specifically designed to condemn Arianism, and required all present to sign it. Its example was eagerly imitated, and for some decades, until the practice fell into disrepute through abuse, synods vied with each other in drafting creeds reflecting the latest nuances of orthodoxy. A further development took place in the early middle ages, when creeds found their way into the church's liturgical worship. Thus in the 6th century, both in the east and in Spain in the west, the so-called Nicene Creed began to be chanted at the Eucharist. Charlemagne adopted the practice, perhaps as a counter to adoptionism (*g.v.*), thus assuring it of still wider currency, and about 1020 Pope Benedict VIII, at the insistence of the emperor Henry II, sanctioned it at Rome. Meanwhile the Apostles' Creed established itself in the daily office in the west.

Church councils after the 4th century issued their doctrinal conclusions as statements of fact rather than of belief; for instance the Council of Chalcedon (451) promulgated as a definition the doctrine of the two natures of Christ, instead of including it in a creed as an article of belief. Hence those dogmas of the Christian faith that received formal definition from the 5th century onward are not enshrined in creeds.

From the numerous credal formularies of the early church three stand out as having attained a unique position and are regarded as possessing special authority. These are the so-called Apostles', Nicene and Athanasian creeds. For this reason, and because of the light they throw on the evolution of creeds generally, they merit closer examination.

**Apostles' Creed.**—The most venerable is the Apostles' Creed, which in English (Latin is its original language) runs:

I believe in God the Father almighty, creator of heaven and earth; and in Jesus Christ, his only son, our Lord, who was conceived by the Holy Spirit, born from the Virgin Mary, suffered under Pontius Pilate, was crucified, dead, and buried, descended to hell, on the third day rose again from the dead, ascended to the heavens, sits at the right hand of God the Father almighty, thence will come to judge the living and the dead. I believe in the Holy Spirit, the holy catholic church, the communion of saints, the remission of sins, the resurrection of the flesh, and eternal life.

This confession is familiar as the baptismal creed of the west; it is also used in the daily offices of the Roman Catholic and Anglican churches and in the services of several leading Protestant

churches. It has no official recognition in the Orthodox churches. Scholarship has shown conclusively that the received text given above (T) is an elaboration of the baptismal creed (R) of the Roman church in the 3rd and 4th centuries. The text of the latter has been recovered in Latin from Rufinus' commentary on the Apostles' Creed (c. 404) and in Greek from a letter sent by Marcellus of Ancyra to Pope Julius I in 340. The fact that the Greek almost certainly represents the original is a testimony to its antiquity. The following is a translation of Rufinus' text:

I believe in God the Father almighty; and in Christ Jesus, his only Son, our Lord, who was born from the Holy Spirit and the Virgin Mary, who under Pontius Pilate was crucified and buried, on the third day rose again from the dead, ascended to the heavens, sits at the right hand of the Father, whence he will come to judge the living and the dead, and in the Holy Spirit, the holy church, the remission of sins, the resurrection of the flesh.

Owing to Rome's immense liturgical influence this speedily became the universal baptismal creed of the west, but local centres did not hesitate to introduce their own variations and additions. It is possible to reconstruct creeds used in the early centuries in Spain, France, Italy, North Africa and the Balkans, and it is clear that, while R is always their basis, they all exhibit characteristic differences. T represents the most mature and sophisticated of these developments. A text almost exactly identical with it appears in the treatise *De singulis libris canonicis scripturarum* written about 710–724 by the Benedictine missionary Priminus, and all the evidence suggests that it reached its final shape in southwestern France in the late 6th or 7th century.

It remains a mystery how this provincial variant of R ousted all the other local versions and eventually displaced R at Rome itself. There is no doubt, however, that Charlemagne, with his interest in liturgical uniformity and his policy of using the creed as an educational instrument, played a decisive part. Once T was established in his dominions, its spread throughout Europe was assured; and since Rome was increasingly exposed from the 9th to the 11th century to the influence of the Frankish liturgy it is easy to surmise how it finally came to adopt the Frankish text of the baptismal creed. Its principal divergences from R either were commonplaces, like the addition of "creator of heaven and earth" and "catholic," or introduced ideas popular in medieval piety such as the descent to hell and the communion of saints.

Attempts have been made to get behind R and explore the beginnings of western creeds. One certain conclusion is that, while R is not identical with Hippolytus' interrogative creed, it is closely related to it. The following, according to his *Apostolic Tradition* is the questionnaire employed at baptism about 200, if not earlier:

Dost thou believe in God the Father almighty? Dost thou believe in Christ Jesus, the Son of God, who was born by the Holy Spirit from the Virgin Mary, who was crucified under Pontius Pilate and died, and rose again on the third day living from the dead, and ascended to the heavens, and sat down at the right hand of the Father, and will come to judge the living and the dead? Dost thou believe in the Holy Spirit in the holy church?

R is obviously a development of this, recast affirmatively, or possibly (since the idea of one credal text for each church was anachronistic at that time) a variant of the same basic stock in use at Rome side by side with it. A second conclusion seems equally certain. The Christology in the central section of R, as has been observed, is easily detachable from its setting; and if this is done, there remains a simple three-clause formulary covering belief in the three Persons. Numerous similar three-clause creeds can be produced from the early centuries (e.g., the interesting one in a papyrus fragment found in 1907 at Der Balyzeh in Egypt). There is also abundant evidence, beginning with the New Testament, that from earliest times a confession of Christ alone existed side by side with Trinitarian confessions. These tended to be come attached to Trinitarian formularies, either being inserted bodily into the second article or tacked on at the end. In the light of this it seems clear that R, as also Hippolytus' questionnaire, originated as the result of the conflation, somewhere in the middle of the 2nd century, of a simple triadic formulary with a fuller Christ confession. (For the Christology of the creed see further JESUS CHRIST: *The Picture of Christ in the Early Church The Apostles' Creed.*)

**Nicene Creed.**—The formulary generally known as the Nicene, more correctly as the Niceno-Constantinopolitan, Creed is the only symbol enjoying ecumenical recognition; it is regarded as authoritative by east and west alike, including the leading Protestant churches. Its principal liturgical use is in the Eucharist in the west and in both baptism and Eucharist in the east; in modern ecumenical discussions it has been accepted as an indispensable standard of belief in any reunited church. The original Greek may be translated:

I believe in one God, the Father almighty, maker of heaven and earth, of all things visible and invisible; and in one Lord Jesus Christ, the only-begotten Son of God, begotten from the Father before all ages, light from light, true God from true God, begotten not made, of one substance with the Father, through whom all things came into existence, who because of us men and because of our salvation came down from heaven, and was incarnate from the Holy Spirit and the Virgin Mary and became man, and was crucified for us under Pontius Pilate, and suffered and was buried, and rose again on the third day according to the Scriptures and ascended to the heavens, and sits at the right hand of the Father, and will come again with glory to judge living and dead, of whose kingdom there will be no end; and in the Holy Spirit, the Lord and the life-giver, who proceeds from the Father, who with the Father and the Son is together worshipped and together glorified, who spoke through the prophets; in one holy, catholic and apostolic church. I confess one baptism for the remission of sins, and look forward to the resurrection of the dead and the life of the world to come.

In the western church the clause "proceeds from the Father" was expanded in the middle ages to "proceeds from the Father and the Son" (see below, *Filioque Clause*).

Until the early 20th century it was universally assumed that this creed (for convenience designated C) was an enlarged version of the famous creed promulgated at the Council of Nicaea (325). It was further assumed that this enlargement had been carried out at the Council of Constantinople (381) with the object of bringing the latter up to date in regard to heresies about the incarnation and the Holy Spirit that had arisen since the Council of Nicaea. A translation of the Greek text of the creed of Nicaea, usually referred to as N, runs as follows:

We believe in one God, the Father almighty, maker of all things visible and invisible; and in one Lord Jesus Christ, the Son of God, begotten from the Father, only-begotten, that is, from the substance of the Father, God from God, light from light, true God from true God, begotten not made, of one substance [Gr. *homoousion*] with the Father, through whom all things came into existence, things in heaven and things on earth, who because of us men and because of our salvation came down and became incarnate, becoming man, suffered and rose again on the third day, ascended to the heavens, and will come to judge the living and the dead; and in the Holy Spirit.

The following anathemas are appended:

But as for those who say, There was when he was not, and, Before being born he was not, and that he came into existence out of nothing, or who assert that the Son of God is of a different hypostasis or substance, or is created, or is subject to alteration or change—these the catholic church anathematizes.

The clauses "that is, from the substance of the Father," "begotten not made" and "of one substance with the Father" were manifestly framed so as to exclude the Arian teaching that the Word is no true Son of the Father but is a creature totally different from and inferior to him in nature. The anathemas are also aimed at specific points in the Arian theology. The anti-Arian clauses, it would seem, have been inserted into a typical Eastern baptismal creed, and the formerly fashionable theory was that this was the old baptismal creed of Caesarea. Eusebius of Caesarea, it will be recalled, had handed in his local creed at the council, and his letter reporting this used to be interpreted as implying that his motive had been to provide a basis for the council's new formulary. The discovery early in the 20th century of the fundamental documents of the synod held at Antioch earlier in 325 set the whole affair in a completely new light. It became evident that Eusebius had been temporarily excommunicated at Antioch because of allegedly unsound teaching, and that his production of his creed at Nicaea was inspired by the desire to secure rehabilitation. There is thus no need to assume any connection between N and the Caesarean creed; and indeed a meticulous, word-for-word comparison of the two formularies confirms

that there is none. On the other hand, scholars have noted that there is a marked resemblance between N and symbols of Syro-Palestinian provenance. It seems clear, therefore, that the committee responsible for drafting N selected some such formulary as its basis, simply interpolating the anti-Arian slogans and attaching the anathemas. The insertion of the key word *homoousion* ("of one substance") was, according to Eusebius, prompted by Constantine himself; it had been previously agreed by the council's steering committee at Nicomedia.

Such being the origin of N, what is to be said of the traditional theory of the relationship of C to it and to the Council of Constantinople? As regards the former question, C undoubtedly takes account of post-Nicene heresies—e.g., of Apollinarianism in "from the Holy Spirit and the Virgin Mary" and of the teaching of Marcellus of Ancyra in "of whose kingdom there will be no end"—and advances a full doctrine of the Holy Spirit's divinity and personality in the third section in moderate language designed to mollify the hesitant. But it is certainly not an enlargement of N. An exhaustive comparison of the two texts reveals convincingly that C's omissions, and equally additions, of numerous words and clauses, often of little or no significance, and also the striking differences between C and N in word order and sentence construction, are impossible to explain on the assumption that the former is the latter expanded. The two are related, but to no greater extent than any other pair of Eastern formularies.

The second half of the traditional theory has been keenly discussed during the 20th century. The suggestion that C was the symbol of the Council of Constantinople (381), it should be pointed out, was first explicitly made at the Council of Chalcedon (451), when it was introduced at the third session as "the faith of the 150 fathers" (i.e., of the Council of Constantinople), but difficulty has been found in accepting it. Criticism has fastened in the first place on the lateness of the evidence. It dates from 70 years after the Council of Constantinople, during which period no hint, it is argued, of any connection between the creed and Constantinople is discernible. Further, no reference to C is discoverable either in the canons of the Council of Constantinople or in the surviving reports of its proceedings. All the contemporary evidence indeed indicates that the 150 fathers confined themselves to ratifying "the Nicene faith," a phrase which has been generally taken to mean restoring the Nicene Creed (N) as the church's standard after the attacks made on it by Arians and others. These doubts seemed clinched by the argument that C must have been in existence well before 391 since it apparently featured in the text of Epiphanius' *Anchoratus*, written in 374.

Such considerations might seem fatal to the traditional hypothesis, but they themselves suffer from serious weaknesses. They fail for example, to explain satisfactorily the attitude of the Chalcedonian fathers. Although C was clearly unfamiliar to the majority when produced, no one ventured to question its claim to be the publication of the Council of Constantinople. Their acceptance of it is incredible unless they were satisfied, and since it was rehearsed by the archdeacon of Constantinople they could refer to the archives of the imperial city. The critics admit that C must have had some connection with Constantinople, but their attempts to show what this was do not bear examination. Again, it now seems established that N, not C, stood in the original text of *Anchoratus* 118; and attention has been drawn to several passages dating from the period 381–451 which suggest that the 150 fathers were understood to have made alterations in N. For these and other reasons opinion has swung in favour of the traditional hypothesis, which has been reinforced by an observation which goes far to meet the chief objection against it. In the 4th and 5th centuries, it has been pointed out, "the Nicene faith" did not denote the Nicene Creed as such, but the characteristic Nicene teaching embodied in the creed. It is thus quite consistent with the contemporary evidence to infer that the work of the Council of Constantinople consisted in reasserting the Nicene doctrine of the *homoousion*, and in doing so either composed or at any rate ratified C. The latter seems more probable, for C does not seem an artificial compilation but has the balance and rhythm of a liturgical piece. The fathers may well have taken over some

existing formulary, touching it up to suit their purposes. It coheres well with this account that the section about the Holy Spirit, while definite, is also cautiously worded, for the aim of the council was conciliatory.

**Filioque Clause.**—The clause "and from the Son" (Lat. *filioque*) began to find its way into the creed in the west in the 6th century. Western theology had been feeling its way toward the doctrine of the double procession (*i.e.*, from both the Father and the Son) of the Holy Spirit ever since Tertullian, but it was Augustine who first formulated it explicitly. Through his influence it soon became universally accepted in the west. The interpolation was first made in Spain, at or soon after the third Council of Toledo (589), and it rapidly spread over Europe. While accepting the doctrine, the popes long rejected the *filioque* from the creed. It was probably Benedict VIII who admitted it, on the occasion when he also agreed to have the creed sung at Mass (*c.* 1020), and it is retained by the Western churches (Roman Catholic, Anglican and Protestant). It has always been rejected, however, by the Eastern churches and deeply resented both as, in their view, contrary to the truth and also as an unauthorized addition to a venerable document.

**Athanasian Creed.**—This creed, often called the *Quicumque vult* from its opening words, is an exposition of orthodox teaching on the Trinity and the incarnation in some 40 verses. It begins and ends with stern warnings that unswerving adherence to the catholic faith is indispensable to salvation. The first and longer section expounds the doctrine of one God in Trinity and Trinity in unity, affirming both that the threeness of the persons in no way divides the divine substance and that the substantial unity does not lessen the reality of the personal distinctions. It also asserts the double procession of the Spirit. The second section teaches that Jesus Christ, while indissolubly one in person, is simultaneously fully divine and fully human, his humanity comprising a rational soul as well as a body. The unity of these two disparate elements, divinity and humanity, in his single person is as complete as the unity of body and soul in a human individual. The creed is entirely western, being unknown in the east until the 12th century at earliest. It is regarded as authoritative in the Roman Catholic, Anglican and leading Protestant communions, and has a limited use in the offices of the two first named.

Since the 17th century there has been general agreement that the *Quicumque vult* is not by Athanasius. It is a Latin document, all existing Greek texts being late and palpably translations; no early evidence links it with Athanasius, and it presupposes doctrinal developments later than his time. Many hypotheses have been advanced for its true date and provenance. Most scholars are satisfied that it must be posterior to Augustine, since much of its language echoes his, while its Trinitarian teaching seems dependent on his *De trinitate*. In 1909, however, H. Brewer argued for Ambrose as its author, pleading that Augustine may well have borrowed from it, and his thesis won widespread acceptance. It has to meet the objections, however, that the creed's Trinitarian teaching is more mature and sophisticated than Ambrose's, that the Christological section almost certainly envisages Nestorianism, which arose after Ambrose's day, and that Ambrose never explicitly taught the double procession and never used the unity of body and soul in man as an analogy of the unity of divinity and manhood in Jesus Christ.

A growing body of opinion looks to south France and the middle or second half of the 5th century for the origin of the Athanasian Creed. The earliest witness to its existence is Caesarius of Arles (*d.* 542), who prefixed it to a collection of his homilies. Its influence in the 6th and 7th centuries seems to have been largely in Spain and southern France, which were closely linked ecclesiastically and liturgically. The hypothesis received valuable support when the lost *Excerpta* of Vincent of Lérins (*d.* 440) came to light in 1940. This is a collection, strongly anti-Nestorian in tone, of extracts from Augustine's writings intended to expound the true doctrine of the Trinity and the incarnation. In it much of the language of the creed, particularly of the Christological section, is verbally anticipated. The likeliest conclusion is not that Vincent was himself its author but that it was composed be-

tween 450 and 500 by some admirer of his, probably also belonging to the school of Lérins, who drew freely on his writings.

**CREEK**, an important American Indian tribe originally living in Georgia and Alabama. The language of the Creek proper is Muskogean, of the Muskogean family of the Gulf linguistic stock (see MUSKOGEAN INDIANS). When they became well known to Europeans in the 18th century, the Creeks were the dominant people in the Creek confederacy, which also included speakers of other Muskogean languages (Hitchiti, Alabama-Koasati) and of non-Muskogean languages (Yuchi, some Natchez and Shawnee). At that time the confederacy consisted of about 50 towns with a total population of perhaps 20,000.

The most important unit of Creek society was the town, consisting of scattered family homesteads associated with a square-ground where they met for important occasions, especially the annual busk or green-corn ceremony. The matrilineal clans of each town were grouped into two parties (moiety), which were important for town government. All the towns of the confederacy were themselves grouped into the white (peace) and red (war) divisions, confederate political organization being modeled on that of the town. Ball games between towns of opposite divisions were conceived of as a substitute for intraconfederacy warfare, and a town defeated in four successive matches transferred to the victors' division.

Creek economy was based on maize-bean-squash agriculture. Hunting was also important, especially during the winter. With increasing European contacts in the 18th century, the Creek confederacy came to occupy a crucial position between the English (and later U.S.), French and Spanish settlements, and vast quantities of diplomatic gifts had an important effect on the economy, as did increasing trade with Europeans (especially for tanned deerskins). Several important political leaders—notably Alexander McGillivray (*q.v.*)—developed during this period, confederacy organization was modified and strengthened, and many European customs such as agricultural practices, Negro slaveholding, house types, loom weaving, etc., were adopted.

As United States power and expansionist policies developed, the Creeks lost their independence, being defeated in the Creek war of 1813-14, and were finally deported to Indian Territory (present Oklahoma) in the 1830s. There they maintained a semi-autonomous Creek nation, with a republican form of government until 1907 (see FIVE CIVILIZED TRIBES).

In 1950 about 20,000 Creeks were living in Oklahoma, many of them entering fully into the life of the state and remaining Creek only by formal affiliation. Others were more conservative, preserving the use of the Creek language, traces of the ancient town organization, and some aspects of Creek religion such as the busk. A remnant remained in southwestern Alabama, where their descendants numbered about 500 in 1950, having lost the Creek language and almost all traces of Creek culture. The Seminole (*q.v.*) are an offshoot from the Creek confederacy of the 18th and early 19th centuries.

**CREEL, GEORGE EDWARD** (1876–1953), U.S. journalist and author who directed publicity for his government during World War I, was born Dec. 1, 1876, in Lafayette county, Mo. He began as a newspaper reporter, became the publisher of a weekly magazine and served as editor of Denver's *Rocky Mountain News*. He was an active supporter of Woodrow Wilson, and when the president in 1917 established a wartime committee on public information Creel was appointed civilian chairman. His services were further utilized as Wilson's personal representative to a number of important conferences. Although he served in several other public positions, his time after 1919 was chiefly devoted to writing books and magazine articles. Creel died in San Francisco, Calif., Oct. 2, 1953. (H. J. Sg.)

**CREEPER**, a small, active, brownish, stiff-tailed bird that climbs the trunks and branches of trees. Creepers constitute the family Certhiidae. They are found in forests throughout the cooler parts of the Northern Hemisphere. The most wide-ranging of the family is the brown creeper or tree creeper (*Certhia familiaris*), a slender, five-inch-long bird. Inconspicuous in plumage—it is dark brown above, with buff spots and stripes, shading to chestnut toward the tail and grayish below becoming white at the throat. The bill is slender, long, and decurved, well fitted for probing crevices for food—insects and their eggs. The tree creeper ascends a tree by using its spiny tipped tail; it descends by flying backward from the trunk and dropping to the ground, breaking its fall by flapping its wings. It never descends a tree headfirst, in the manner of a nuthatch. The nest, a cup made of twigs, bark, and moss, is wedged behind a loose bit of bark; it may contain five to eight translucent white eggs speckled with rust. The eggs hatch in about 15 days and the young are nestlings for about three weeks.

On the European continent a second species, the short-toed tree creeper (*C. brachydactyla*), is found. This is similar to *C. familiaris* in appearance but has a different song and lives in gardens and parks rather than in woodland.

Allied to the tree creeper, but without its stiff tail feathers, is the genus *Tichodroma*, the single member of which is the beautiful wall creeper (*T. muraria*) of the Alps and some other mountainous parts of Europe and Asia. (It is thought by some to be an aberrant nuthatch.) The wall creeper is occasionally seen fluttering up the face of a rock, conspicuous because of the scarlet-crimson of its wing coverts and its white spotted primaries. Its bright hue is hardly visible when the bird is at rest, at which time it presents a dingy appearance of gray and black. It has a wide range, extending from Spain to China. Several creeperlike birds native to Australia are problematical members of the Certhiidae; their affinities may lie with the nuthatches.

**CREEVEY, THOMAS** (1768–1838), English M.P. and placeman, whose friendship with the Whig leaders and consequent inside knowledge of contemporary politics and society enabled him fully to indulge his talent for gossip. He was born in Liverpool in March 1768, allegedly the son of William Creevey, a local merchant, but he is believed by some to have been the illegitimate son of Charles William, 1st earl of Sefton. He went to Queen's college, Cambridge, and graduated as seventh wrangler (1789). He became a student at the Inner Temple, transferred to Gray's Inn (1791) and was called to the bar (1794). He entered parliament, through the duke of Norfolk's nomination, as member for Thetford (1802), and married Mrs. Eleanor Ord, a widow with six children and a comfortable income. A close friend of Charles (afterward earl) Grey and a follower of Charles James Fox, Creevey was made secretary to the board of control in the brief ministry of "all the talents" (1806). He was defeated at Thetford in 1818 and sat for Appleby from 1820 to 1826; he was appointed treasurer of the ordnance when his party next came into power (1830) and Lord Melbourne made him treasurer of Greenwich hospital (1834). He died suddenly on Feb. 5, 1838, in his lodgings in Jermyn street, London.

Creevey had a shrewd political sense and in opposition in the house of commons he was highly effective. His parliamentary gifts were the subject of an admiring portrait by Thomas Barnes, editor of the *Times* from 1817 to 1841 (*Parliamentary Portraits* published anonymously, 1815). He also had an unrivaled capacity

for giving pleasure in social life. Lord Sefton's daughter said of him "he has added to all the pleasures and diminished all the sorrows of my life," and many contemporaries would have echoed her words. The *Creevey Papers* include many of his letters which, as lively and as cheerful as his personality and characterized by an almost Pepsian outspokenness, give a valuable picture of the political and social life of the late Georgian era. His correspondence was treasured by his wife's family.

See Sir H. Maxwell (ed.), *The Creevey Papers* (1903); J. Gore, *Creevey's Life and Times* (1934). (R. T. B. F.)

**KREFELD**; see KREFELD.

**CREIGHTON, MANDELL** (1843–1901), English historian, and bishop successively of Peterborough and London, whose scholarship and administrative ability ensured him a lasting reputation in both capacities, was born at Carlisle on July 5, 1843. He was educated at Durham and Merton college, Oxford, of which he became a fellow in 1866, and later a tutor, and was largely responsible for starting the intercollegiate system of lectures in history. In 1872 he married Louise von Glehn, herself later the author of several historical textbooks. In the following year he was ordained to the priesthood and in 1875 became vicar of Embleton, Northumberland. He proved an excellent pastor and administrator, and assisted in the foundation of the new diocese of Newcastle upon Tyne, of which he was made honorary canon in 1883.

Meanwhile he maintained his academic connection by examining in the history finals and by serving as select preacher at Oxford. He also began to write history. In 1875 appeared his *History of Rome*, and in 1876 *The Age of Elizabeth and Life of Simon de Montfort*. At the same time he undertook the editorship of two series, *Epochs of English History* and *Historical Biographies*, writing for the former a short inaugural volume, *The Shilling History of England*. He also began work on his magnum opus, *History of the Papacy*, the first two volumes of which appeared in 1882. In 1884 he was appointed first Dixie professor of ecclesiastical history at Cambridge. He infused new life into historical studies there by showing himself to be both a popular lecturer and a learned conductor of seminars. He was appointed residentiary canon of Worcester in 1885 and became the first editor of the *English Historical Review* in 1886. He also continued his own writing, producing the third and fourth volumes of the *History of the Papacy* (1887), *Cardinal Wolsey* (1888) and *Carlisle* (1889). In 1877 he began editing a new series of textbooks, *Epochs of Church History*.

In 1890 he was nominated to a canonry at Windsor, but before he could be installed was called to the bishopric of Peterborough (1891). His six years there showed afresh his powers of administration and negotiation. In education, while supporting the principles of the 1870 act, he furthered the cause of the denominational and voluntary schools. He took an active interest in social and industrial concerns, and helped to secure the compromise that ended the strike (1895) in the Leicester boot factories. These new responsibilities necessarily curtailed his historical studies, but he became the first chairman of the Church Historical society in 1894, and in 1896 published *Queen Elizabeth* and delivered the Romanes lecture on "The English National Character."

In 1897 he was translated to the exacting see of London. There his determined Anglicanism, combining attachment to the liturgical traditions of the church with a scholar's readiness to welcome new light from every quarter, enabled him to exercise a steady influence in the ritualist controversies of the day. He supported archbishop Frederick Temple's able summary of the situation in the Lincoln judgment of 1899 and did much to draw the disputants together in his round table conference on the doctrine of Holy Communion in 1900. Throughout he tried to establish that the distinctive characteristic of the Church of England was "the appeal to sound learning." Worn out by his labours he died on Jan. 14, 1901.

See *Life and Letters of Mandell Creighton* by his wife, 2 vol. (1904) and articles in *Dictionary of English Church History*, 2nd ed. (1950) and in *Dictionary of National Biography*, First Supp. (1901) (J. W. C. W.)

**CRELLE, AUGUST LEOPOLD** (1780–1855), German mathematician and engineer, who sponsored the work of many young scientists of his day, was born at Eichwerder, Wriezen, on March 11, 1780. Crelle was a man of many interests and great organizing ability, and worked for the advancement of the exact sciences. By profession he was a civil engineer in the service of the Prussian government, and he built the first railroad in Germany.

Crelle was more interested in educational matters, however, and in 1828 he left the technical institute in which he was employed to take up service with the ministry of ecclesiastical affairs and public education. He published a considerable number of textbooks, and his multiplication tables have been used widely and reprinted many times, but his great service to mathematics was the founding of the *Journal für die reine und angewandte Mathematik*, now known as *Crelle's Journal*. Niels Abel and Jakob Steiner encouraged Crelle in this venture, and were the chief contributors to the first numbers; Karl Jacobi was another early contributor.

Without Crelle's generous encouragement, some of Abel's greatest work might never have been completed and published. Crelle also founded the *Journal für Baukunst*. He died on Oct. 6, 1855, at Berlin.

**CREMATION.** Cremation is the reduction of human remains to ash. There is ample evidence that cremation was widely practised in the ancient world. The Romans copied it from the Etruscans and the Greeks, and cremation was the fashionable mode of disposal throughout the Roman empire among the aristocratic classes. In Europe cremation ceased to be common with the growth of the Christian doctrine that attached considerable importance to the resurrection of the physical body. But the practice remained common throughout the eastern world: thus the Indians and the Japanese have always been cremationists, as have the Burmese. The Chinese, however, have never adopted cremation since it is the desire of every Chinese to be buried in the soil of his country, no matter where he may die.

The modern development of cremation dates from 1874, when the queen's surgeon, Sir Henry Thompson, published a book entitled *Cremation: the Treatment of the Body After Death*. In this book he said that the proposal to adopt cremation in recent times originally proceeded from Italy. Papers on the subject had appeared in 1866, and two Italian scientists had experimented over the intervening period. It was in 1873 that Thompson had seen a model of one of these experimental furnaces at the Great exhibition in Vienna and, with memories of the appalling conditions of cemeteries in Britain, was attracted to the idea of the sanitary disposal of the dead by this Italian method. He consequently took steps to organize what he called the Cremation Society of England; its leading supporters were outstanding writers, artists and scientists of the period: Sir John Tenniel and Anthony Trollope and Sir John Millais were closely associated with Thompson and were signatories to the document that brought the Cremation society into existence. The purpose of this society, according to the statement drawn up on Jan. 13, 1874, was to propagate the idea of cremation since the promoters "disapproved of the present system of burying the dead and wished to substitute some method which would rapidly resolve the body into its component elements by a process which could not offend the living and would render the remains perfectly innocuous."

Although Thompson's book and his subsequent writings roused great interest, the new society met with considerable opposition and prejudice and four years elapsed before the group was able to obtain a suitable site at Woking, Surrey, for establishing a crematorium. Even then it was impossible to proceed because of opposition of the church and the home secretary. It was not until 1883 that the attempt in south Wales by Dr. William Price to cremate the body of his infant child resulted in a legal action, producing in 1884 the judgment that cremation was a legal process provided it did not cause a nuisance. Fortified by this judgment the society proceeded to advertise that cremation was available at its Woking crematorium, but it was many years before cremations were offered regularly. In the early days the cremations

were carried out according to principles laid down by the council of the Cremation society and, despite many efforts to introduce legislation in the house of commons to regulate the process, it was not until 1902 that the first Cremation act was passed and regulations were drawn up under that act. In the meantime, six other crematoria had been established in various parts of the country. Nevertheless progress was slow until the close of World War II, when local authorities, faced with the difficult problem of finding the necessary land for all the social needs of their citizens, concluded that it was no longer possible to maintain the burial system, which was wasteful of land, and that every effort should be made to encourage the adoption of cremation. The result is seen in the great growth not only in the number of crematoria and in the number of cremations carried out but also in the percentage of cremations in relation to total deaths. Thus, by the second half of the 20th century there were in Great Britain about 200,000 cremations annually, representing about one-third of the total deaths, and there were more than 160 crematoria in operation. Considerable advance was made in every aspect of the subject after World War II. Much thought was given to the architectural aspects involved and the development of the "gardens of remembrance" attached to each crematorium where the ashes of the dead may be buried or scattered. At the same time the technical aspect was not neglected, so that the process by which the dead body is reduced to ash is carried out in a speedy and seemly manner considerably beyond the original conception of Thompson and his friends.

This increasing acceptance of the idea of cremation is observable in many parts of the world. In the Scandinavian countries and in all the countries of Europe where there are cremation societies, crematoria are established in most of the densely populated areas and there is an ever-increasing number of cremations. Progress was even more marked in Australia and New Zealand where, in each case, the cremations exceed 30% of the total deaths.

The law differs widely, however, in various countries. In Britain the process is controlled by the Cremation acts of 1902 and 1952 and by the regulations of the home secretary drawn up under these two acts, which require that the medical practitioner in attendance at death shall complete a form in which he certifies the cause of death and that a second and impartial medical practitioner shall confirm this finding. Although the law is not so rigid in most other countries, the general principle is to ensure that cremation shall not be a means of concealing crime and that proper safeguards shall be established in the public interest.

In the United States the cremation movement did not progress in quite the same measure as in Europe. Its beginning as an established practice can be traced back to 1876, when F. J. Le Moine of Washington, Pa., built a rather rudimentary crematorium that consisted almost wholly of a furnace, without embellishments, and carried out a cremation there. He himself was also cremated there a short time later. The practice of cremation nevertheless made progress. According to the figures produced by the Cremation Association of America there were more than 230 crematoria in operation throughout the United States by the second half of the 20th century and during 1954–59 approximately 300,000 cremations were carried out. After 1937, the national cremation societies throughout the world combined for consultative purposes in the International Cremation federation, with headquarters in London; the federation holds triennial congresses and seeks to promote cremation as a universal practice.

**CRÉMAZIE, (JOSEPH) OCTAVE** (1827–1879). Canadian poet who may justly be called the father of French-Canadian poetry, was born at Quebec April 16, 1827, and was educated at

the Seminary of Quebec. An extraordinarily learned man, he started in 1848 a bookshop which became the centre of a literary circle including among others F. Gameau and Louis Fréchette (*qq.v.*) and Étienne Parent. In 1860 Crémazie and his friends founded the first literary school of Quebec and in 1861 began issuing a monthly magazine, *Les Soirées Canadiennes*, with the object of perpetuating the folklore of French Canada before it was forgotten. Crémazie also published poems in the *Journal de Québec* from about 1854 onward. He became involved in business difficulties and to escape their consequences departed in 1862 for France, where he spent the rest of his life in great poverty under the assumed name of Jules Fontaine. During that time he wrote the gloomy poem "Promenade des trois morts," which remained unfinished, and a journal *Siege de Paris*, describing the siege of 1870, which he witnessed. His poetry was characterized by a patriotic love of Canada and Canadian nature, shown especially in the "Chant du vieux soldat canadien." His "Drapeau de Carillon" (1858) almost became a national song of Canada. Crémazie died at Le Havre Jan. 16, 1879. In 1906 Philippe Hébert erected a monument in St. Louis square, Montreal, to his memory. His *Oeuvres Complètes* were collected by his friends in 1883.

See P. G. Roy, *Autour de Crémazie* (1945); S. Marion, *Octave Crémazie, Précurseur de Romantisme Canadien-Français* (1946). (C. Cr.)

**CRÈME DE MENTHE.** A peppermint liqueur, water-white in its natural state but usually of a beautiful dark-green colour when sold, since pure vegetable colouring is then added. Its strength is normally 29% alcohol by volume. Mint is a natural digestive and the essence of a species of garden mint is obtained by distillation; when it is completely free from fusel oils, or vegetable impurities, it is used to flavour a natural spirit. For the best crème de menthe, cognac is used. (C. C. H. F.)

**CREMER, SIR WILLIAM RANDAL** (1838–1908), English trade unionist and pacifist who won the Nobel Peace Prize for his advocacy of international arbitration, was born at Fareham, Wiltshire, on March 18, 1838. In 1860 he was one of the founders of the Amalgamated Society of Carpenters and Joiners. Cremer was secretary of the British section of the First International (*see* INTERNATIONAL, THE) but resigned because of dissensions with Robert Applegarth. In 1870–71 he formed a workingmen's committee for the advocacy of neutrality in the Franco-German War. This developed into the Workmen's Peace Association, of which Cremer was secretary until his death in London on July 22, 1908. In 1868 and 1874 he stood unsuccessfully for Parliament as a workingmen's candidate, but he was elected as a "Lib.-Lab." in 1885 and was a member until 1895 and from 1900 to 1908. At the 1906 election neither the Parliamentary Committee of the Trades Union Congress nor the Labour Representation Committee would endorse his candidature. In 1903 Cremer won the Nobel Peace Prize. He was knighted in 1907.

See Howard Evans, *Sir Randal Cremer* (1911).

(A. Bri.)

**CRÉMIEUX, (ISAAC) ADOLPHE** (1796–1880), French lawyer and statesman, responsible for the *Décret Crémieux* of Oct. 24, 1870, which enfranchized the Jews in Algeria, was born at Nîmes on April 30, 1796, of Jewish parents. After practising at the bar at Nîmes, he became an advocate at the supreme court of appeal in Paris, where in Dec. 1830 he defended Martial de Guernon-Ranville, one of Charles X's former ministers. Elected deputy for Chinon in 1842, he played a prominent part in the revolution of 1848, becoming minister of justice in the provisional government. He at first supported the candidature of Prince Louis Napoleon for the presidency, while voting with the extreme left, but later withdrew his support and was imprisoned after the *coup d'état* of Dec. 2, 1851. On his release he returned to the bar until 1869, when he was elected a deputy for Paris. Minister of justice in the government of national defense (1870–71), he represented Algiers in the national assembly from 1871 till 1875, when he was elected a senator for life. He died in Paris on Feb. 10, 1880.

See S. Posener, *Adolphe Crémieux*, 2 vol. (1933–34).

**CREMONA, LUIGI** (1830–1903), Italian mathematician and pedagogue, was born at Pavia. He fought as a volunteer in the abortive north Italian uprising of 1848–49, and after studying

under Francesco Brioschi at the University of Pavia became elementary mathematical master at the gymnasium and lyceum of Cremona, and afterward at Milan.

In 1860 he became professor of higher geometry at Bologna, and in 1866 professor of higher geometry and graphical statics at the higher technical college of Milan. In 1873 Cremona became professor of higher mathematics at Rome, where he organized the college of engineering. His reputation was by that time European. In 1879 he became a corresponding member of the British Royal society and a senator of the kingdom of Italy. His life was devoted to the reform of higher mathematical teaching in Italy.

Cremona was a prolific contributor to mathematical journals of Italy and Europe, and some of his books were translated into English; e.g., his manual on *Graphical Statics* and his *Elements of Projective Geometry* (trans. by C. Leudesdorf). His reputation mainly rests on his *Introduzione ad una teoria geometrica delle curve piane*, which proclaims him a follower of the Steinerian or synthetical school of geometers.

**CREMONA**, a city in Lombardy, Italy, on the north bank of the Po river and capital of Cremona province, lies in the fertile Lombard plain 85½ km. (53 mi.) S.E. of Milan by road and 98 km. (61 mi.) by rail. Pop. (1961) 76,173 (commune).

The main centre of Cremona is the cathedral square. The cathedral (consecrated 1190) is a finely proportioned Romanesque basilica notable for frescoes by Cremonese and other north Italian painters (Boccaccio Boccacino; Antonio and Bernardino Campi; Altobello da-Melone; Gian Francesco Bembo; Girólamo Romanino; Giovanni Pordenone). It is connected by a double arcade, the Loggia della Bertazzola, by Lorenzo Trotti (1493–1505), with the Torrazzo (1284), reputedly the highest bell tower in Italy (397 ft.). Nearby the octagonal baptistery dates from 1167. Other buildings of the middle ages are the Loggia dei Militi (1292), the churches of S. Michele, S. Vincenzo, S. Lorenzo and S. Bassano, and the Gothic city hall (1206–45). Renaissance buildings include the Raimondi, Affaitati, Vidoni, Fodri and Stanga palaces, adorned with terracotta moldings characteristic of the Cremonese style. The church of S. Sigismondo in the east of the town is notable for frescoes by Camillo Boccacino and the Campi family; that of San Pietro al Po in the south has paintings by Bernardino Gatti and A. Campi; that of Sant' Agostino has frescoes by Bonifacio Bembo; that of Sta. Margherita was built and painted by Giulio Campi (*q.v.*). Neo-classicism is represented by the façade of the church of Sant' Agata (1848) and by the Mina, Barbò and Palavicino palaces.

Cremona is an important market for cattle and dairy and other produce; an International Dairy Cattle fair is held. Manufactures include food products, agricultural machinery, bricks and pianos. Nougat has long been a speciality of the town's confectioners but the supreme Cremonese products were the violins made in the 16th–18th centuries by the Amati family and their pupils Guarneri and Antonio Stradivari (*qq.v.*). The School of Violin and Viola Makers has a museum of antique stringed instruments, including some by the Cremonese masters, in the Palazzo dell' Arte. The university school of musical paleography is unique in Italy.

**History.**—Cremona was founded by the Romans on the site of an earlier Gallic village of the Cenomani in about 219 B.C. Virgil, who was born at Andes near Mantua, was sent to school at Cremona; hence his *Mantua, vae! miserae nimium vicina Cremonae* ("Mantua, alas, too near the unhappy Cremona"). This was quoted by Jonathan Swift on seeing a violin whisked off the table by a lady's mantle. In the dark ages the town was repeatedly sacked by the Goths and Huns before being rebuilt by the Lombards in the 7th century. In 1098 it became an independent commune covering a wide area; it was threatened by Milan and therefore sided with Frederick Barbarossa, but finally joined the Lombard league in 1167. It came within the orbit of the Visconti family (*q.v.*) of Milan in 1334, and within that of the Sforzas (*q.v.*) when Bianca Maria Visconti married Francesco Sforza (1441). After repeated attacks by Venice, Cremona was taken into the Venetian republic 1499–1509, coming under Spanish domination soon afterward and under that of Austria in 1707. Thereafter its history was that of Lombardy.

**Cremona province**, bounded on the west approximately by the Adda river, south by the Po and on the northeast and east approximately by the Oglio river, has a population (1961) of 346,171. Area 1,756 sq.km. (678 sq.mi.). The province, which has a network of irrigation canals, is almost wholly arable land and pasture, less than 5% being forest and woodland. Dairy farming and stock raising are important and the chief crops are rice, wheat, corn (maize) and flax; some raw silk is produced. The chief towns are Cremona; Crema and Soresina between Cremona and Milan; Soncino in the northeast; and Casalmaggiore on the Po river in the southeast. Cremona is an episcopal see in the archdiocese of Milan. (A. Pu.)

**CREODONT**, any of the extinct omnivorous and flesh-eating mammals comprising a group that is usually considered a sub-order of the Carnivora. The creodonts were the principal flesh-eating animals of the northern continents during the Paleocene and Eocene (extending from about 40,000,000 to 70,000,000 years ago). Although they included a number of families of diverse or partly parallel specialization, they were all distinguished by certain primitive characters: a small brain; separate scaphoid and lunar bones of the carpus; and lack of ossification of the tympanic bulla. They lacked the dental specialization of modern land carnivores: instead of having the carnassials, the shearing teeth of typical carnivores, creodonts had other teeth enlarged and specialized. They differ from Insectivora and resemble the modern Carnivora in the enlargement of the canines into powerful tearing teeth, in the heavier muzzle and jaws with strong zygomatic arches, and in a number of other skeletal characters.

The oldest family referred to the Creodonta is the Arctocyonidae of Paleocene and Early Eocene times. These evidently omnivorous forms had primitive tritubercular teeth and subequal molars. The arctocyonids show many resemblances to the earliest hoofed mammals (*Protogonodon* to the phenacodontid condylarths; *Deltatherium* to the Pantodonta, etc.). These resemblances have been regarded as supporting evidence for the view that carnivores and hoofed mammals had a common ancestry. The possibility exists, however, that the Arctocyonidae, or at least many of the forms currently placed in the family, should be regarded as belonging to the great hoofed mammal group, the Ungulata.

The latest Paleocene and Eocene Oxyaenidae (sometimes considered a subfamily, Oxyaeninae, of the Arctocyonidae) included a variety of truly predaceous types: *Oxyaena* resembled a wolverine; *Patriofelis* reached the size of a bear with massive hyena-like teeth; and *Palaeonictis* had more feline characters.

The related Hyaenodontidae included many and various types in North America, Europe, Asia and Africa. In the earliest forms, *Sinopa*, *Proviverra* and *Tritemnodon*, of the Early and Middle Eocene, the teeth were tuberculosectorial, the molars not very different in size, and the skull was long and slender. The proportions of body and limbs were like those of the modern viverrids (civet family) except for the very long and heavy tail. *Limnocyon* was analogous in teeth, proportions and probable habits, to modern weasels and martens. In *Pterodon* and *Hyaenodon* of the Late Eocene and Oligocene, the teeth were more completely sectorial and the body was larger; the proportions of skull and limbs were more like those of wolves. The subfamily Machaeroidinae forms an interesting branch of the family. The known genera, *Machaeroides* and *Apataelurus*, of the Eocene of North America, were remarkably similar to the later sabre-toothed tigers. Hyaenodontids were widespread in the Late Eocene and Oligocene and late survivors occurred in the Miocene of Africa and the Pliocene of India.

The most peculiarly specialized family of the creodonts, the Mesonychidae, were distinguished by the absence of any shearing action of the teeth; the cusps of the teeth were high, round and

blunt-tipped. The muzzle and jaws were elongate, the limbs and feet in some species slender and cursorial as in the wolf. Some species attained the size and massive proportions of the larger bears; the toes were tipped with flattened hoofs instead of claws. These creodonts are found in the Eocene rocks of western North America, western Europe and central Asia. Several of them equaled or exceeded the largest living Carnivora in size of skull. In the Late Eocene rocks of Mongolia is found the gigantic *Andrewsarchus* with a skull three feet long; this is the largest known carnivorous mammal, even allowing for the probability that the skull was relatively large in proportion to the skeleton.

It is perhaps open to question whether the creodonts are really referable to the order Carnivora. The earliest true carnivores, which date from Middle Paleocene time, were by then already fully recognizable as carnivores; no connection has yet been established between them and any of the creodont families.

See also CARNIVORE.

Soc.*, n.s., vol. 30 (1937); A. S. Romer, *Vertebrate Paleontology*, 2nd ed. (1945); W. B. Scott, *A History of Land Mammals in the Western Hemisphere*, 2nd ed. (1957). (B. Pu.)

**CREOLE** (French *créole*; Spanish *criollo*), a term used originally (16th century) to denote persons born in the West Indies of Spanish parents, as distinguished from immigrants direct from Spain, Negroes and Indians. It has come to be used by and with reference to descendants of non-Indian peoples born and settled in the West Indies and on the American continents in some areas of Spanish, Portuguese and French colonization. In the United States the term is used chiefly to designate the French-speaking descendants of the early French and Spanish settlers in Louisiana (see LOUISIANA: History; NEW ORLEANS: Population Characteristics). The patois dialects founded on French and Spanish are referred to as Creole languages (see PIDGIN).

The concept Creole has undergone many modifications during the four centuries of cultural and social development and racial mixture in the new world. It has both biological and cultural connotations with respect to which there is considerable local (national, regional, ethnic, class) variation in significance. In a very general way, Creole may be used to identify a non-European and non-Indian way of life and set of values associated (in Latin America) in a fairly complex manner with different segments of the mestizo (culturally and racially mixed) population. The Creole way of life is symbolized by distinctive work patterns, leisure activities, modes of dress, habits of speech, food preferences and the like. This symbolism defies facile generalization, however, from one Latin American country to the next and even varies with respect to special segments of the population within a single nation. An idea of the complexity of association may be had by selecting one country, such as Peru, as a concrete example.

In Peru the word *criollo* is used both as a noun and an adjective, with sharply different meanings. As a noun, the word is used to classify persons of predominantly Spanish descent who have family roots in the colonial period. Most of these Creoles are members of "high society" (*alta sociedad*), some stemming from old-line families (*familias de abolengo*) and others from the land-hungry element who fought successfully for Peru's independence from Spain and who thereby acquired wealth and social position. These upper-class Creoles constitute a very small segment of the population. They are members of the oldest and wealthiest families in the provincial capitals, identified with the preservation of an elegant colonial tradition, or members of wealthy European and Lima who, however, tend to identify with modern European and North American cultural norms. Bordering on the adjectival use of the term is the manner in which Creole is used to distinguish the coastal people (*costeños*) from highland Indians (*serranos*). This usage emphasizes two different ways of life and geographical provenience, regardless of the class membership or family heritage of the *costeño*.

As an adjective, *criollo* is not a class-bound concept, although it has most significant associations with the lower classes of the Peruvian coast—social and economic categories comprised of

BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

SKULL OF HYAENODON, A CREODONT OF EARLY TERTIARY AGE, WHICH IN SIZE AND STRUCTURE WAS SOMEWHAT SIMILAR TO THE WOLF

mestizos and Negroes. Important expressions of the Creole way of life are the ability to turn a situation to one's advantage; speak wittily and persuasively on a wide range of subjects; be masculine (*macho*) in the sense of a successful and promiscuous lover; and relish well-seasoned (*picante*) foods associated mostly with plebeian taste. Hard work, often field labour, is part of the Creole way of life among the lower classes; but work is avoided when possible and leisure is handsomely exploited in fiestas, where the *marinera* and the *vals criollo* are danced and copious amounts of *pisco* are drunk. Fiesta life has its roots in the hacienda system, and occasions members of *alta sociedad* (hacienda owners and their friends) to mingle with their workers and local townsmen on saints' days, etc., when they return to play the traditional role of *patrón* and, participating in the revelry, may become *muy criollo* (very creole). In a larger sense, creolism (*criollismo*) signifies living life with a special gusto involving a national orientation, pride in country and a vigorous identification with Peru's present and future. *Criollismo* is an adaptive concept within the limitations of the Creole "spirit." Foreign ideas are reworked into the Creole pattern of life, acquiring new significance. This malleability indicates the process, in all societies having Creole segments, whereby numerous special adaptations have been made in the Creole tradition.

Simmons, "The Criollo Outlook in the Mestizo Culture of Coastal Peru," *American Anthropologist*, vol. 57, no. 1, pp. 107–117 (1955); J. L. F. Broussard, *Louisiana Creole Dialect* (1942); H. L. Ballowe, *Creole Folk Tales* (1942). (L. C. FA.)

**CREON**, the name of two figures in Greek legend. (1) Creon, son of Lycaethus, was king of Corinth and father of Glauce or Creüsa, the second wife of Jason, for whom Jason abandoned Medea. (2) Creon, the brother of Jocasta, was successor to Oedipus as king of Thebes (see *ANTIGONE*).

**CREOSOTE**. The term creosote is applied loosely to two entirely different substances, coal-tar creosote and wood-tar creosote. In commerce creosote refers to coal-tar creosote, a complex mixture of organic compounds, largely hydrocarbons, obtained by the distillation of coal tar (*q.v.*). In pharmaceutical circles creosote invariably refers to wood-tar creosote, a mixture of phenolic compounds extracted from a distillate of wood tar.

**Coal-Tar Creosote**, an oily distillate of coal tar, is a complex mixture of organic compounds. Most of the coal-tar creosote produced is used for the prevention of the deterioration of wood by plants, insects and marine animals. The decay of wood is caused by minute plants, called fungi; these parasitic plants attach themselves to the wood, use it for food and thereby destroy it. Of the large number of insects which destroy wood the termites (*q.v.*) are responsible for the largest part of the wood destruction caused by this biological group. The mollusks (shipworms) and the crustaceans are the two groups of wood-boring marine animals which damage wood submerged in the salt waters of the tropical and temperate regions; they are more abundant in the warmer waters but even in the colder regions are a serious menace; usually wood submerged in fresh water is not attacked by the borers.

Coal-tar creosote was an important fuel in the British Isles during World War II. In a substantial manner it replaced the petroleum fuels which had to be imported. Coal-tar creosote was itself used as a fuel and it was blended with coal-tar pitch to make other liquid fuels. Some coal-tar creosote is used in the manufacture of lampblack or carbon black (*q.v.*), a carbon of a particular and peculiar kind. Lampblack is made by burning creosote oil with incomplete combustion. The volume, speed, temperature and humidity of the air are adjusted for the desired grade of lampblack.

**Wood-Treatment Processes.**—To prevent the deterioration of wood by organisms, the wood is impregnated with coal-tar creosote. The most satisfactory way to inject the creosote into the wood is by means of pressure. The pressure treatment of wood is by either of two processes: the full-cell process, in which the cells in the treated portion of the wood remain either partially or completely filled with creosote; or the empty-cell process, in which the cell walls in the treated portion of the wood are coated with creosote, the cell itself being empty or only partially filled. The wood is

loaded onto steel cars, the cars are run into a steel pressure cylinder, usually 6 ft. or more in diameter and 100 ft. to 150 ft. in length, and the cylinder is closed.

The next step in the treatment depends upon which of the two pressure processes is used. In the full-cell (Bethell) process, the cylinder is evacuated and without first breaking the vacuum it is filled with creosote oil, previously heated to about 200° F. and maintained at this temperature during the treating period. The pressure in the cylinder is then raised to about 190 lb. per square inch and is maintained at this pressure until the wood has absorbed the desired amount of creosote. The creosote is then pumped out of the cylinder, the cylinder is again evacuated and the wood is removed from the cylinder.

In the empty-cell (Rueping) process, instead of evacuating the cylinder before filling it with creosote oil, compressed air is introduced and the air pressure is maintained in the cylinder while it is being filled with the creosote. After the cylinder is filled with creosote the operations are the same as in the full-cell process.

The amount of creosote oil retained by the wood is usually expressed in terms of the number of pounds per cubic foot of wood. The amount desired to be retained depends upon the use to which the wood will be put. Building lumber is usually given an 8-lb. treatment, telegraph poles an 8-lb. to 12-lb. treatment, piling a 16-lb. to 24-lb. treatment, railroad ties a 6-lb. to 10-lb. treatment, creosoted block flooring about a 6-lb. treatment. Records show that pressure-creosoted wood may be expected to give a service life of 50 years or more. The post-office department in England has creosoted poles still in service 70 years after erection.

In addition to treatment by the pressure process, wood is impregnated with coal-tar creosote by a hot- and cold-bath open-tank process. In this process the wood is heated for one or more hours in the creosote oil at a temperature of from 180° F. to 220° F., whereby the moisture and air in the wood expand and are partially driven out. Then the wood is quickly transferred to a tank of creosote having a temperature of about 100° F. It is left in this tank for one hour or more; the plunging of the warm wood into the cool creosote oil causes the air and moisture in the wood to contract and thereby suck in the creosote oil. The hot- and cold-bath process is used for the butt treatment of posts and poles.

The dipping process is another way of injecting creosote into wood. In this process the wood is submerged in creosote oil and heated at from 200° F. to 220° F. for about 15 minutes or more. This allows the creosote oil to fill all the checks and defects in the wood, but the penetration of the oil into the wood is only slight.

Sometimes wood is merely given a brush treatment or painting with the creosote.

Coal-tar creosotes vary considerably in their composition and therefore in their preservative value. Considerable attention has been given to the relative preservative qualities of low-residue creosote oils (*i.e.*, those oils which have only a small amount of the fraction distilling above 355° C.) and of high-residue creosote oils (the oils have a large amount of the fraction distilling above 355° C.). The facts indicate that a well-balanced coal-tar creosote oil consisting of both low-boiling and high-boiling distillates is the superior wood preservative.

**Chemistry.**—Coal-tar creosote consists largely of aromatic hydrocarbons (naphthalene, methylnaphthalenes, fluorene, anthracene, pyrene, etc.) but also contains some tar acids (phenols, cresols, xylenols, naphthols, etc.) and some tar bases (pyridines, quinolines, acridines, etc.). Because of its complex and variable chemical composition, it is necessary to rely on its physical properties to characterize coal-tar creosote.

The specific gravity of coal-tar creosote at 38° C. compared with water at 15.5° C. is not less than 1.03; the specific gravity of the fraction of creosote distilling between 235° C. and 315° C. is usually not lower than 1.025 at 38° C. to 15.5° C.; the fraction distilling between 315° C. and 355° C. usually has a specific gravity not lower than 1.085 at 38° C. to 15.5° C. Ordinarily, coal-tar creosote does not have more than 5% of a fraction distilling up to 210° C. and not more than 25% of a fraction distilling up to 235° C.; the amount distilling above 355° C. varies from about 10% to about 40%.

**Wood-Tar Creosote** is a specially refined part of the alkalisoluble constituents of a fraction of distillate oil obtained from hardwood tar, usually beechwood tar. (See TARS, LOW-TEMPERATURE.) It is an oily liquid which distills over the approximate range 203° C. to 220° C. It is composed largely of a mixture of monohydric phenols (phenol, cresols, xylenols) and the methyl ethers of dihydric phenols (guaiacol).

Beechwood creosote was once used extensively for pharmaceutical purposes. Medicinally, it has been used only to a limited extent, mainly in the treatment of respiratory infections such as bronchitis. (F. E. C.)

**CREOSOTE BUSH** (*Larrea tridentata*), a North American shrub of the caltrop family (Zygophyllaceae), called also greasewood, native to and characteristic of the sparse scrubby vegetation of desert plains in the southwestern United States and adjacent Mexico. It is an evergreen, strong-smelling, tangle-branched shrub, 2–5 ft. high, with brittle stems and very leafy branches. The small, olive-green, resinous leaves emit a tarry odour. The bright yellow flowers, a half-inch across, appearing in early spring, are followed by small, white, densely woolly globose seed capsules.

At low altitudes and sometimes up to 3,000 ft. the creosote bush forms, in the Mohave, Colorado, Gila and similar deserts, a characteristic zone of vegetation called the *Larrea* belt. The plant is cultivated as an ornamental in desert gardens.

**CREPE**, a family of fabrics of various constructions and weights but all possessing a crinkled or granular surface. The surface effects are achieved through weaving variations, chemical treatment or embossing. The weaving method usually employed is to weave the fabric with crepe yarn, a hard-twist yarn produced either with a higher number of twists per inch than ordinary yarn or with alternate "S" and "Z" twists. In the "S" twist the twist of the yarn resembles the centre part of the letter "S"; in the "Z" twist the resemblance is to the centre part of the letter "Z." Another weaving variation is to leave out certain risers (interlacings of warp over filler threads) present in plain weave in order to increase the float of yarn from one to three. The fabric is made from all of the major fibres, natural or man-made. Surface textures range from fine, flat crepes to pebbled and mossy effects; some surfaces resemble tree bark.

Popular crepes include Canton, crepe-back satin, crepe de Chine,orgette, marocain, faille, lingerie, mossy, romaine and rough. The family name is derived from the French *crêpe*, meaning crisped, frizzled or wrinkled. The original spelling in English was crape. (G. E. L.)

**CREPE DE CHINE**, a very light and fine plain woven dress fabric produced either with all-silk warp and weft or else with a silk warp and hard-spun worsted weft. A crepe de Chine texture has a slightly crepe character, a feature produced by the use of weft yarns spun with the twist running in reverse directions and known as right-hand and left-hand twist, respectively. During weaving, the picks of weft are inserted in the order of "two-and-two" (i.e., with two picks of weft with a right-hand twist and two picks with a left-hand twist). Hence, during the finishing operation, owing to the abnormal amount of twist in the picks of weft, these tend to untwist and recover their normal condition. They thereby cause the characteristic effect of typical crepe de Chine. Crepe de Chine textures of artificial silk are now common and are often difficult to distinguish from the true silk.

**CREPUSCULAR RAYS** are shafts of light which are seen just after the sun has set and which extend over the western sky radiating from the position of the sun below the horizon. They form only when the sun has set behind an irregularly shaped cloud or mountain which lets the rays of the sun pass through a cloud in bands. The radiating appearance of the bands is caused by perspective, as demonstrated by the fact that when on rare occasions the rays extend across the entire sky, they appear to converge again on the eastern horizon. The name is sometimes applied to shafts of sunlight seen when the sun shines through cumulus clouds, from which phenomenon arises the erroneous popular expression "the sun is drawing water."

The derivation of the word (Latin *crepusculum*, "twilight") indicates that it should be applied only to the after-sunset occur-

rence. See also TWILIGHT.

**CRERAR, JOHN** (1827–1889), U.S. philanthropist who endowed the library named after him in Chicago, Ill., was born in New York city on March 8, 1827. In 1862 he went to Chicago, where he directed a plant that manufactured railway equipment; he became one of the original members of the Pullman Palace Car company when it was incorporated in 1867. He was also a bank and railroad director and served as president of the Chicago and Joliet Railway company. Crerar died a bachelor in Chicago on Oct. 19, 1889.

His bequest for a statue of Abraham Lincoln led to the creation of Augustus Saint-Gaudens' seated figure of Lincoln in Chicago. Crerar did not specifically provide in his will for a library devoted to the sciences and technology, which the John Crerar library became, though he expressly wished to exclude certain novels and works that he felt undermined morals. The library contains special collections in the various sciences and in medicine and the history of medicine.

**CRES** (Ital. *CHERSO*), a Yugoslav island in the Adriatic sea in the Quarnero group, lies off the east coast of Istria. In 1945 Cres and the adjoining island of Losinj (Lussino), previously Italian, passed to Yugoslavia. Pop. (1961) Cres 4,113; Losinj, 5,746.

Cres, 64 km. (40 mi.) long and 11.5 km. (7 mi.) wide, has a total area of 404 sq.km. (156 sq.mi.). It is separated from Losinj by a navigable channel which is believed to be an artificial one made by the Romans. Both islands are structurally a part of the Karst plateau of Istria. The most interesting feature is Lake Vrana with drinking water 63 ft. below sea level. Wine, olive oil and fruits are produced in both islands but Cres is chiefly devoted to sheep raising. (V. DE L.)

**CRESCAS, HASDAI** (c. 1340–1412), Jewish philosopher, who played a prominent part in Jewish communal affairs, was born at Barcelona, Spain, a protégé of the royal house of Aragon. His principal work is the *Or Adonai* ("The Light of the Lord"), which, in opposition to Maimonides and Gersonides, seeks to free religion from intellectualism and stresses the love of God as the only way to eternal bliss.

Again opposing his predecessors, he interprets creation as the eternal and necessary emanation of existence from God. His critique of Aristotelian physics foreshadowed a new conception of the universe and influenced Pico della Mirandola and possibly Giordano Bruno. Spinoza mentions Crescas in a letter and seems to owe something to him.

Unlike his Jewish predecessors, Crescas rejects the doctrine of absolute free will. He distinguishes, however, between predetermination in the sense of fatalism and causal determination and admits that the human will, though free to choose, is determined by the causality of motives. His view goes back to Averroes, to Avicenna and to the Stoics.

Crescas wrote a *Refutation of the Cardinal Principles of the Christians* in Spanish. (A. AN.)

**CRESCENT** (Lat. *crescens*, "growing"), a word used particularly of the moon and applied to the moon's shape in its first quarter. It was a religious symbol from the earliest times and figured, for example, in the worship of Astarte. Later it became the symbol of the Byzantine empire, supposedly because the sudden appearance of the moon saved the city from a surprise attack. It once was thought that the Ottoman Turks adopted the crescent for their own flags after capturing Constantinople in 1453 but in fact they had been using the symbol for at least a century before that, as it appeared on the standards of their infantry under Sultan Orkhan (c. 1326–c. 1360). In that case, however, the crescent may have been of different origin, formed by the base-to-base conjunction of two claw or horn amulets, as on horse brasses. Whatever its origin, the crescent became closely associated with the Ottoman empire (appearing on military and naval standards and on the tops of minarets), its successor states and the world of Islam in general. It may be seen today, as a white crescent with from one to five stars, on the national flags of Turkey, Pakistan, the Federation of Malaya (and its component states), Tunisia, Libya and the Maldives Islands, and in red as

(H. R. B.)

the symbol of the Red Crescent, the Muslim equivalent of the Red Cross organization.

The Fertile Crescent comprises Iraq, the northern and coastal areas of Syria and Lebanon and Israel, forming a crescent-shaped belt of fertile land.

In heraldry the crescent was originally a mark of great honour adopted by many returned crusaders, particularly in France. In England, with the horns vertical, it became an honourable ordinary. With the horns turned to the dexter it was known as "increscent," and to the sinister as "decrecent." In modern heraldry it is used as a difference to indicate second sons of a family and their descendants. In western chivalry there have been two orders of the Crescent, the first founded in 1268 by Charles I of Naples, the second in 1448 by René d'Anjou. Neither of these, nor Selim III's order, was very long-lived.

In architecture a crescent is a street or place built as the arc of a circle. A common street name in England, it was first used of the Royal crescent in Bath in the 18th century. (A. D. A.)

**CRESCENTII** (CRESCENZI), a Roman family which played an important part in the history of Rome and the papacy from the middle of the 10th to the beginning of the 11th century. Its extensive possessions were situated mainly in the Sabina. The Crescentii a *Caballo Marmoreo* and the Crescentii de *Theodora* may both be descended from one Crescentius recorded in 901. It is doubtful whether Pope John XIII belonged to the former. Crescentius (I) de *Theodora* (d. 984?) led a revolt in 974 against Benedict VI who was imprisoned in the Castel S. Angelo and then assassinated; but the antipope Boniface VII did not prevail against the new "imperial" pope, Benedict VII, under whose pontificate (974-983) the Crescentii seem to have suffered a political setback. After the emperor Otto II's death their fortunes revived, and John, probably Crescentius' son, assumed the title of *patricius* of Rome and appears to have controlled the election of the new pope, John XV, in 985. In 996, Crescentius, probably John's brother, led a rising against Gregory V, whose cousin the emperor Otto III reinstated him in 998; after being besieged by Otto in the Castel S. Angelo, Crescentius was executed on April 29, 998. His son John (II) was the last of the family to wield political power in Rome: after Otto's death (1002), he became *patricius* and henceforth practically governed the city; he died in 1012. After that, the Stefaniani branch, descended from Stefania, sister of Crescentius (I) de *Theodora*, declined; the Ottaviani, descended from John (II)'s brother-in-law Octavianus, retained the rectorate of the Sabina until the beginning of the 12th century.

Bossi, "I Crescenzi . . .," *Dissertationi della Pontificia Accademia Romana di Archeologia*, vol. xii (1915) and "I Crescenzi di Sabina Stefaniani e Ottaviani (dal 1012 al 1106)," *Archivio della Società Romana di Storia Patria*, vol. xli (1918); C. Cecchelli, *I Crescenzi, i Savelli, i Cenci* (1942); P. Brezzi, *Roma e l'impero medioevale* (1947). (N. R.)

**CREASILAS** (fl. 5th century B.C.), a Cretan sculptor who worked mostly in Athens. He was a contemporary of Phidias, and the sculptor of an Amazon in the competition at Ephesus about 440 B.C. His Amazon was perhaps the figure, of which copies are extant, represented as drawing back her chiton from a wound under the right breast. Another work of Cresilas of which copies appear to survive is the portrait of the Athenian statesman Pericles. This portrait confirms the statement of ancient critics that Cresilas was an artist who idealized and added nobility to noble men. Copies of a statue of Diomedes are probably also derived from Cresilas.

**BIBLIOGRAPHY.**—Gisela M. A. Richter, *The Sculpture and Sculptors of the Greeks* (1950); G. Lippold, *Handbuch der Archäologie*, iii, 1 (1950); P. Orlandini, "Kresilas," *Atti e Memorie (Lincei)* (1952). (C. C. V.)

**CRESOLS** or METHYL PHENOLS. A mixture of the three isomeric cresols (ortho-, meta- and para-) is obtained from coal tar and also from cracked petroleum naphthas. The formula of the cresols is  $\text{CH}_3\text{C}_6\text{H}_4\text{OH}$ . The o-cresol is separated quite readily and fairly completely from the other two isomers. The boiling points of m-cresol and p-cresol are so close together (see COAL TAR) that it is not practical to separate them by fractional distillation; the separation may be accomplished by chemical means. Cresylic acid, a mixture of the three cresols containing some phenol

and various amounts of xlenols (dimethylphenols), is an important commercial chemical. It is used in the manufacture of phenol-formaldehyde resins, tricresyl phosphate and in disinfectants.

In 1956 a multimillion-pound-per-year plant was erected in the U.S. for the synthesis of p-cresol. The process used involves the oxidation of p-cymene (p-isopropyltoluene) to the corresponding hydroperoxide, and the latter is then hydrolyzed to p-cresol.

(F. E. Cr.)

**CRISPI, DANIELE** (1590/92-1630), Italian mannerist painter, was born at Busto Arsizio, near Milan, in 1590/92. He was a pupil of G. B. Crespi and of G. C. Procaccini, and became an exponent of that form of mannerism which is characterized by extreme elongation of the figures and especially the limbs. He worked exclusively in Lombardy, and there are works by him in many Milanese churches, including the Certosa di Garegnano, near Milan, in which are his scenes from the life of St. Bruno, generally reckoned his masterpiece. Other works are in the Certosa di Pavia, and in the Brera gallery, Ambrosiana and Castello Sforzesco in Milan. He died in Milan, of plague, in 1630. (P. J. My.)

**CRISPI, GIOVANNI BATTISTA** (called IL CERANO) (1575/76-1632), Italian painter, who was influenced by Gaudenzio Ferrari and Camillo Procaccini but whose own style is important in the development of Lombard realism before Caravaggio, was born at Cerano near Novara and died in Milan about Oct. 23, 1632. (In the register of deaths his age is given as 56, so he must have been born about 1575/76 and not, as formerly believed, c. 1557.) He studied in Rome and Venice and returned to Milan under the patronage of Federigo Cardinal Borromeo, who made him head of the painting section of the Accademia Ambrosiana in 1620. His most celebrated works are a series of ten pictures of the life of St. Charles Borromeo in Milan cathedral (1602-10). He was also active as a sculptor and architect. (P. J. My.)

**CRISPI, GIUSEPPE MARIA** (called LO SPAGNUOLO) (1665-1747), Italian genre painter, was born in Bologna on March 16, 1665. He was a pupil of Domenico Canuti but formed his style principally on the example of the Carracci and on the study of the Venetians Barocci and Correggio, seen during his extensive travels. He was, however, unique in his employment of strong chiaroscuro and in his interest in genre subjects; both these interests were to be taken up in the 18th century in Venice by G. B. Piazzetta and Pietro Longhi. His famous series of the "Seven Sacraments" (Dresden gallery) shows both his preoccupations to advantage. Other works by him are in Bologna. His son, Luigi Crespi, wrote his life in his *Vite de' pittori bolognesi* . . . (1769). He died on July 16, 1747, in Bologna. (P. J. My.)

**CRESS**, a common name for many plants of the mustard family (Cruciferae; q.v.) whose sharp-flavoured basal leaves are often used in salads, seasonings and garnishes. Water cress is probably the best known (see WATER CRESS), but other edible cresses include garden cress (*Lepidium sativum*), a peppergrass; upland or winter cresses (*Barbarea verna* and *B. vulgaris*), often weedy herbs; and bitter cress (*Cardamine* species). Among several ornamental plants called cress are rock cress (*Arabis* species; see ARABIS) and Indian cress, the common garden nasturtium (*Tropaeolum majus*; see NASTURTIUM).

**CRESENT, CHARLES** (1685-1768), French furniture maker, sculptor and metalworker, who occupied a prominent position in 18th-century European art and whose works are among the most beautiful pieces of French furniture of the period, was born at Amiens on Dec. 16, 1685. Grandson of the cabinetmaker Charles Cressent and son of the sculptor François Cressent, he practised both professions. It is not known when he went to Paris, but it was probably about 1710. At first he worked for the son of the cabinetmaker André Charles Boulle, came under the influence of the designer G. M. Oppenordt and the painter Antoine Watteau and formed a friendship with the sculptor François Girardon. As early as 1715 he was appointed official cabinetmaker to the duc d'Orléans, regent of France, and later he occupied the same position for his son. In 1719 he became a member of the Académie de Saint-Luc, an eminent situation that brought Cressent important orders. He made furniture for foreign courts

(Portugal, Bavaria) and for the houses of the wealthy in France but does not seem to have worked for Louis XV. For the regent's son he made one of his masterpieces, the famous medal cabinet (in the Bibliothèque Nationale, Paris). Cressent was also an experienced collector. Having developed his taste in the world of art, he formed a fine collection of pictures and *objets d'art*, which, however, he voluntarily dispersed. He died in Paris on Jan. 10, 1768.

Cressent not only designed the models and made the furniture himself, but he also carved magnificent mountings of gilded bronze for them. In this respect his skill was comparable to that of his contemporary, Jacques Caffieri. The cabinetmakers' corporation instituted proceedings against Cressent, who, although a cabinetmaker and in spite of his privileges, had not the right to work bronzes on his premises, and they were seized in his workshop.

The total absence of signatures makes it difficult to date Cressent's production, so recognizable by his personal style. The first works, still very much in the manner of Louis XIV, have affinities with Boulle's work. In the following period (about 1730–50) his artistry is balanced, retaining its elegant strength and avoiding the excess of rococo; from this period can be dated the charming *espagnolettes* (female figures generally fixed to the corners of tables), most characteristic of Cressent's style. Finally, after 1750, his work was inspired by a return to the antique.

The Louvre (Paris) and the Wallace collection (London) are specially rich in furniture by Cressent.

See M. J. Ballot, "Charles Cressent," *Archives de l'art français*, vol. x (1919); F. de Salverte, *Les Ebénistes français du XVIIIe siècle* (1953). (S. Gr.)

**CRESSY, HUGH PAULIN** (in religion SERENUS) (c. 1605–1674), English Benedictine historian, apologist and spiritual writer, was born at Thorpe-Salvin, Yorkshire, and educated at Merton college, Oxford. He became chaplain to Sir Thomas Wentworth (later earl of Strafford) and subsequently to Lucius Cary (later Lord Falkland); he was also dean of Leighlin, Ire., and canon of Windsor. In 1646 he joined the Roman Catholic Church, partly owing to the writings of Father Augustine Baker, and became a monk of St. Gregory's, Douai, in 1649. Returning to England after the Restoration he was appointed chaplain to Queen Catherine of Braganza at Somerset house. He died at East Grinstead on Aug. 10, 1674. His *Exomologesis*, an account of his conversion, appeared in Paris in 1647; he also wrote a large *Church-History of Brittany [i.e., Britain] . . . to the Norman Conquest* (part i, 1668; part ii, discovered in 1856, is still unprinted) and several controversial tracts. His chief significance, however, is as editor of the mystics Walter Hilton (1659) and Julian of Norwich (1670) and, above all, as the skilful compiler, from manuscript material left by Father Baker, of the spiritual classic *Sancta Sophia* (1657). He thus presented to his generation and to posterity the traditional ascetical and mystical teaching of medieval England, developed and completed by the saints and mystics of the Counter-Reformation.

See J. Gillow, *Bibliographical Dictionary of English Catholics*, vol. 1, pp. 592–596 (1885). There is a sympathetic portrait of Cressy in J. H. Shorthouse's novel *John Inglesant* (1902). (M. D. K.)

**CRESTON, PAUL** (1906– ), U.S. composer, whose modernistic style is made accessible and effective through rhythmic vivacity and harmonic euphony, was born in New York city, Oct. 10, 1906, in an Italo-American family; his real name is Joseph Guttovaggio. He studied organ but was self-taught in composition. Among his works are five symphonies (1940, 1944, 1950, 1951, 1955), some of them with programmatic connotations (the third symphony is subtitled *Three Mysteries*); *Two Choric Dances* for orchestra (1938); *Threnody* for orchestra (1938); saxophone concerto (1941); piano concerto (1949); *Walt Whitman*, symphonic poem (1951); *Invocation and Dance* for orchestra (1953); chamber music for various combinations; sacred vocal pieces, and piano music. Creston was also active as a lecturer and conductor. In 1956 he was elected president of the National Association for American Composers and Conductors. (N. Sv.)

**CRESWELL CRAGS**, a ravine about 500 yd. long cutting through a localized ridge of Permian limestone near Creswell in

northeastern Derbyshire, Eng. Its precise geological history is not known, and the rivulet it carries would have been quite incapable of erosion on the scale seen. Two parallel walls of cliffs on either bank rise to about 50 ft in height in places. Both escarpments are dissected by gullies and pierced at several points by considerable caves. The latter contained important deposits of the Upper Pleistocene Age, whose excavation has yielded one of the most important series of extinct vertebrate faunal remains accompanied by the implements of Paleolithic hunters known in Britain.

The earliest, recorded scientific excavations of these deposits took place in 1875 and were continued for a number of years by Sir William Boyd Dawkins. Further excavations were undertaken by A. L. Armstrong in 1924 and subsequently, and his work was followed in 1959 and 1960 by detailed investigations undertaken by R. V. S. Wright and C. B. M. McBurney.

The principal sites examined were Robin Hood's cave, Pin Hole, Mother Grundy's Parlour and Church Hole. The best-attested human occupation in all of these belongs to the so-called Creswellian culture, now widely regarded as a provincial variant of the later Magdalenian culture of southwestern France and assigned to the final episodes of the last or Würm glaciation. On the evidence of radiocarbon analyses, this last glaciation is believed to have fallen between the 13th and 9th millennia B.C.

Traces of earlier Paleolithic stages include Mousterian artifacts from Pin Hole, Robin Hood's cave and less certainly from the other two.

Well-characterized implements of the British variant of the Proto-Solutrean are also available from Church Hole. The accompanying mammalian fauna includes reindeer, woolly rhinoceros, mammoth and wild horse.

An earlier faunal assemblage, presumably of the Last Interglacial or Riss-Wurm Age, from Mother Grundy's Parlour includes *Hippopotamus major* and *Rhinoceros leptorhinus*, both indicative of temperate conditions. A quartz industry claimed to be associated with this assemblage has not been confirmed.

(C. B. M. McB.)

**CRETACEOUS SYSTEM**, in geology, a vertical sequence of rocks deposited toward the end of the Mesozoic era, or time of intermediate forms of life following the Jurassic period and immediately preceding the Cenozoic era—the era of recent or modern life. Many rocks of Cretaceous age are of notable economic importance and are used for a variety of purposes: building stones, ceramic products, glass sand and cement. The most important products, however, are oil and gas and coal and water. Oil deposits are widespread in North America, South America and northern Africa. Thick coal deposits in North America cover an immense area (100,000 sq. mi.) and are also found in Germany, Japan and New Zealand. It is mostly of bituminous and lignitic

quality. Porous Cretaceous sandstones are locally important sources of artesian water.

The Cretaceous was a period of dramatic change in the distribution of land and sea on the earth and in the plants and animals that inhabited it; it was the time of the much discussed extinction of the dinosaurs and other groups of animals; and toward the end of the Cretaceous the flowering plants became the dominant vegetation cover of the land areas of the world. The Cretaceous period lasted approximately 75,000,000 years, beginning about 130,000,000 to 140,000,000 years ago; it was characterized by notable mountain-building activity and by vast inundations of continental areas by the sea. Volcanic activity was lively at times along the major submarine depressions, the geosynclines that ringed the Pacific ocean and extended in approximate east-west direction across northern South America, the Mediterranean area and from there diagonally toward Australia to form an ancient sea called the Tethys. The climate of the Cretaceous is generally considered to have been warm to temperate even in the higher latitudes.

**The Cretaceous Rocks.**—The name Cretaceous (as *Crétacé*, from Lat. *creta*, "chalk") in its present application was suggested by Omalius d'Halloy in 1822. It refers to a characteristic rock deposited during late Cretaceous time over much of northwestern Europe where, exposed along the English channel, it forms a familiar landmark (the white cliffs of Dover). Chalk, however, is not the predominant type of rock formed during this period. On the land thick deposits of sandstone, shale, coal and conglomerate were accumulated; in the seas (besides chalk) mudstone, limestone and some thick beds of material of volcanic origin were formed. The vertical sequence of these rocks is usually divided into two portions, the Lower and the Upper Cretaceous sequences. In order to compare the relative ages of rock sequences the world over, a standard of named stages representing succeeding time intervals was established for the European sequence, beginning with the Neocomian (the oldest) and ending with the Danian. The chart shows in much simplified form the relative age of Cretaceous rock deposits in various parts of the world. Age correlation of Cretaceous beds in geographically separated parts of the world is based, in the case of marine sediments, largely on widely distributed species of ammonites which are among the more reliable guide or index fossils of the period. In the continental deposits plant assemblages and dinosaurs have been used to identify and correlate the beds of rocks. (See FOSSIL.)

### PHYSICAL HISTORY

**Mountain-Building Activity.**—Sedimentary rocks are the product of destruction by erosion of highlands and mountain ranges. During the Cretaceous period many ancient mountain systems and old uplands as well as mountain ranges formed during the latter part of the Jurassic were severely dissected or virtually leveled; fresh movements of the earth's crust occurred in many parts of the world and at different times during the period, and many of the mountain ranges thus formed were likewise reduced to peneplains. This explains the vast quantity of Cretaceous deposits. Local mountain-building activity occurred at the very beginning of the Cretaceous period in extreme western North America, in Europe and in the far east (Japan), and again at the end of the Lower Cretaceous. In North America the end of the Cretaceous coincides with very profound crustal movements (Laramide revolution) that gave rise to the Rocky mountains.

**Distribution of Land and Sea.**—The distribution of water and land in the early part of the Cretaceous period was notably different from what it is today (see figs. 1 and 2). The North American continent was partially covered by advancing seas both in the north and in the south. The Caribbean area was an island. Large parts of western Europe and the Mediterranean area east to the Caspian sea were covered by the Tethys and the ancient North sea. An eastern extension of the Tethys geosyncline separated peninsular India from the Asiatic continent.

A long arm of the Arctic ocean penetrated deeply into the Russian plain. Toward late Cretaceous time the transgression of the seas over former land areas reached its maximum extent. North America became completely bisected by an immense, shallow sea

DRAWN FOR "ENCYCLOPEDIA BRITANNICA" BY MAIDI WIEDE

FIG. 1.—DISTRIBUTION OF LAND AND SEA DURING LOWER (EARLY) CRETACEOUS TIME

that spanned the continent lengthwise from the Gulf of Mexico to the Arctic ocean. The continent of Africa likewise became divided into two land masses with a very shallow, lagoonal sea arm connecting the Tethys with the South Atlantic. Almost all of western Europe, except for a few islands and the Scandinavian shield, as well as large areas of the Asiatic continent lay covered by the expanding Tethys. While the picture of land and water distribution during the Cretaceous is generally one of gradually increasing surface area of the seas, the opposite trend, regressive movements with emergence of land areas, occurred locally in a number of places and at various times. A striking example of this is seen in the long sea arm that extended from the Arctic ocean across the Russian plain toward the Caspian sea. It was formed in the late Jurassic period and existed until just prior to Aptian time in the Cretaceous, when it was replaced by an arm of the Tethys entering the Russian plain from the south. The fossil faunas enclosed in the sediments of these sea arms are thus of strikingly different nature, one belonging to the cool arctic province, the other to the subtropical Tethys.

**Volcanic Activity.**—It has long been recognized that volcanic activity accompanies major crustal disturbances of the earth, and that volcanoes usually are arranged in lines that follow the edges of structurally active geosynclinal troughs. In Cretaceous time (as was true in earlier periods) such major geosynclines ringed the Pacific ocean and were an outstanding feature of the Tethys sea. Volcanic activity occurred all through the Cretaceous period along these synclinal basins, but not everywhere at the same time or with the same intensity.

In the early phase of the period, volcanic activity centred primarily around the Pacific where by Danian or late Cretaceous time it became very active along the eastern fringe of the Asiatic continent. Activity along the geosynclines of the Tethys occurred with varying intensity during the late Cretaceous; it was particularly notable along the southern edge of the Asiatic continent (Indochina, peninsular India, Black sea area) and around the Car-

ibbean land mass. It must be noted that the edges of the shallow epicontinental seas are devoid of volcanic activity because these basins did not form by crustal buckling and sinking as did the active geosynclines.

**Climates.**—The climate of the Cretaceous is considered to have been temperate to warm with a mean annual temperature (at 40° to 90° N. latitude) above 50° F. (E. Dorf, 1957). There is no evidence to suggest the presence of polar icecaps, and vegetation of temperate- or even subtropical-zone character is recorded from high latitudes (Greenland, Alaska). However, at the beginning of the period the climate was somewhat cooler and it rapidly deteriorated at the very end, although by comparison with the present-day climate it must still have been rather mild. The fact that vast land masses and mountain ranges were leveled by erosion and the presence, locally, of a dense, lush cover of vegetation that produced extensive coal deposits indicate that there was a great deal of rainfall; hence the climate was probably not only warm, but moist as well. While it is possible to characterize the climate of a given period in general terms applicable to the world as a whole, it must be kept in mind that the climate of any given locality is determined to a notable extent by local factors such as mountain ranges, marine currents and wind patterns. For example, the climate of extreme western Europe up until mid-Neocomian time was no doubt influenced in the north by the relatively cool North sea that washed the shores of Scandinavia and the British Isles southward to eastern England. Parts of France, on the other hand, lay in contact with a shallow arm of the warm Tethys. The narrow strip of land between the two seas vanished by Aptian time and the waters became mixed; it seems very probable that the effect of this process was a tendency toward climatic moderation both north and south of the original barrier.

## LIFE OF THE PERIOD

As in the preceding period, the Jurassic, it is possible in the Cretaceous to distinguish two major faunal belts around the world: an equatorial belt and a boreal or northern belt. To these may be added an austral (australian or southern) province. The organisms that lived in these regions are of distinctive character much as are the organisms within the faunal or life provinces of today (see *GEOLOGY: Paleontology*). To a notable extent, paleogeographic maps, such as those illustrated, are based on the nature of the faunal assemblages preserved in rock sequences; for exam-

ple, it is faunal evidence that permits the conclusion that the epicontinental sea covering much of the Russian plain was connected with the Arctic ocean in the early Cretaceous, but with the Tethys by Aptian time.

The history of the organisms during this period contributes a fascinating chapter to the over-all history of life on the earth. Certain organisms became plentiful and varied whereas others evidently reached an evolutionary climax and became extinct.

**Vegetation.**—At the beginning of the Cretaceous period the predominant vegetation cover of the land consisted of primitive vascular plants or gymnosperms (*q.v.*): scouring rushes, abundant conifers, ferns, cycads and their relatives and ginkgoes. The true flowering plants (angiosperms) were on the scene but they constituted a minor element in the floras of this time, at least in the fossil record. Since the periodic shedding of the foliage coupled with a resting phase and the evolution of durable seeds in the angiosperms are very probably adaptations to seasonal and fairly rigorous climatic conditions, it has been suggested that they might have inhabited the highlands (where the chances of their preservation as fossils would have been extremely limited). Toward the middle of the period, however, fossil angiosperms are known in increasing numbers and in the late Cretaceous they replaced the gymnosperms as the dominant vegetation cover on all continents. In fact the flora assumed, by this time, a distinctly modern character with such familiar trees as beech, sassafras, fig, magnolia, poplar, oak, maple, walnut and many other well-known trees and shrubs, grasses and vegetables. Thus viewed from the fossil record it would seem that the flowering plants underwent rapid evolutionary radiation during the Cretaceous period. This may be so, but it is at least possible that the fossil record merely documents the fact that the angiosperms, already present in great variety, expanded their range into the lowlands (where their chances for preservation in rapidly accumulating sediments were better) in the course of Cretaceous time and replaced to a large measure the earlier gymnosperm vegetation cover.

**Animal Life.**—Among the microorganisms the Foraminifera, one-celled animals with minute calcareous skeletons, occur in vast abundance and variety. In late Cretaceous time the skeletons of these tiny creatures, settling to the sea bottom after death of the animals, formed thick deposits of chalk, especially in western Europe. In recent years these animals have been studied in great detail because of their usefulness, especially to the oil industry, in

the correlation of rock samples from well cuttings (*see* FORAMINIFERA). Sponges and corals were locally abundant in parts of the Tethys sea and elsewhere, but they and the brachiopods never played a major role in the faunas of this period. Of the echinoderms it was the sea urchins that populated the Tethys waters in rather large numbers, and some species were sufficiently widespread to serve now as guide fossils. The sea lilies (crinoids), on the other hand, were rare. The most abundant and varied invertebrate animals of this period were the mollusks. To the historical geologist they are of great interest because many species evolved rapidly and thus persisted for only a brief time while achieving wide geographic distribution—two requirements that make an organism a useful guide fossil. Among the lamellibranches (clams and relatives) the most characteristic types were the rudistids, massive sessile shells that formed reeflike masses and were typical members of the warm-water faunas especially abundant in the Mediterranean section of the Tethys. Oyster beds, likewise, were of notable importance. The marine gastropods (snails), whose anatomy is unknown except for the shapes of their shells, were locally common and many of them had characteristic shapes and ornamentations. While the clams and snails survived the end of the Cretaceous period, most of the cephalopods (relatives of the squids and *Nautilus*) did not. Nor did the belemnites (squidlike animals with long clublike backward projections from their internal skeletons) and the unusually varied group of the ammonites, distant relatives of the living *Nautilus*. Both these groups were very conspicuous elements of the Mesozoic faunas and both died out at the end of the Cretaceous.

Among the vertebrates the fishes present a picture similar to that of the plants in the sense that the earlier ganoid (*q.v.*) or garlike fishes were largely replaced by the modern bony fishes, the teleosts. What little is known of the amphibians suggests that modern types were already present in the early phase of the period.

For the reptiles, in contrast, the Cretaceous brings to a close their rule on the earth. The dinosaurs, the most conspicuous land animals, gradually died away until only the ceratopsians (horned dinosaurs) were left and they, too, did not survive the end of the period (*see* DINOSAUR). In the sea the ichthyosaurs (fish reptiles), the plesiosaurs and the marine lizards, the mosasaurs, all highly successful predators of the oceans, vanished, as did the flying reptiles (pterosaurs). Only the turtles, lizards and snakes, the crocodiles and the rhynchocephalians survived to the present. Little is known of the birds of the period and the mammals, although present since the end of the Triassic, were small and rather inconspicuous creatures.

Numerous possible causes have been suggested to account for this dramatic faunal upheaval during late Cretaceous time, but no single factor could have been responsible. It would seem clear however, that the world-wide structural disturbances resulting in intense orogenic or mountain-building and volcanic activity toward the close of the period resulted in profound environmental alterations that required physical adaptability greater than that of the highly specialized reptiles and ammonites.

**CRETE** (Gr. ΚΡΗΤΗ; KRETE), the largest island of Greece and, after Sicily, Sardinia, Cyprus and Corsica, the largest island in the Mediterranean, is situated between 34° 55' and 35° 41' N. latitude and between 23° 30' and 26° 19' E. longitude. Its northern extremity, Cape Sidero (Akra Sidheros), is distant about 110 mi. from Cape Krio (Akra Krios) in Asia Minor, the interval

being partly filled by the islands of Karpathos and Rhodes; its northwestern extremity, Cape Vouxa (Akra Vouxa, also called Grabusa), is about 60 mi. from Akra Malea in the Morea (Peloponnese). Crete thus forms the natural southern boundary of the Aegean. The island's area is 3,189 sq. mi. Its population in 1961 was 483,075. The region of Crete has an area of 3,217 sq. mi. and had a population of 483,258 in 1961.

## I. PHYSICAL GEOGRAPHY

**1. Geology and Structure.**—The island of Crete is a remnant of a range of mountains which formerly linked the chains of the Peloponnese with those of southwestern Turkey. This range was thrown up, like those of the Greek mainland, during the earth movements of Tertiary times and took the shape of a wide arc, of which the east-west trending range of Crete is the most southerly section. Subsequently this mountain range was broken by rifts and dislocations and much of it foundered beneath the sea. In what is now Crete, these fractures left the four main mountain masses standing above three fallen sections which, after being covered by the sea in late Tertiary times, are now isthmuses composed of Pliocene sediments. During the process of rifting, the residual mountain masses of Crete were upheaved and tilted toward the north and northeast, with the result that while on the south they fall abruptly into the sea along a straight coast line, they descend more gradually to the north in a series of natural steps, to meet a more indented and gently shelving shore.

The very porous limestone rocks of Crete rest on the impervious basement beds of the island and springs of water are commonly found at their junction. The basement rocks are chiefly found in the extremities of the island, especially in the western districts around the Gulf of Kisamos (Kolpos Kisamou) and Palaiohora (Selino Kastelli). There the topography is much more gentle and rounded and surface streams are far more common than in the limestone regions with their precipitous slopes and underground drainage. These metamorphic rocks of western Crete, which are largely Triassic in origin, form a series about 9,000 to 10,000 ft. in thickness and include gypsum, dolomite, conglomerates, phyllites and a basic series of eruptive rocks (gabbros, peridotites and serpentines).

Resting on these basal formations are sedimentary rocks several thousand feet thick of Jurassic, Cretaceous and Eocene age, consisting largely of unstratified gray and black limestones but including some sandstones and conglomerates. At the western foot of the Psiloriti (Idhi; ancient Ida) massif calcareous beds with corals and brachiopods (*Rhynchonella inconstans*, etc.) have been

found, the fossils indicating the horizon of the Kimeridge clay. Lower Cretaceous limestones and schists, with radiolarian cherts, are extensively developed; and in many parts of the island Upper Cretaceous limestones with *Rudista* and Eocene beds with nummulites have been found. The arrangement of these series is complicated by a great thrust plane which has brought the Jurassic and Lower Cretaceous beds upon the Upper Cretaceous and Eocene beds. The Miocene marine beds (with *Clypeaster*) lie almost undisturbed upon the coasts and the low-lying ground, especially in the isthmuses of Ierapetra and Rethimnon. They are largely composed of conglomerates, though they include also some marls, chalks and sandstones, which have weathered into a low rolling landscape. With the Jurassic beds is associated an extensive series of eruptive rocks (gabbro, peridotite, serpentine, diorite, granite, etc.) which outcrop at the eastern end of the Asidheroto range and to the south of the Lasithi (Dhikti) mountains. They are chiefly of Jurassic age, but the eruptions may have continued into the Lower Cretaceous. The small plains of alluvial Upper Tertiary and Quaternary deposits, in particular those of Mesara and Canea (Khania), include some of the most fertile districts of Crete.

**2. Physiography.**—The island is of elongated form; its length from east to west is 152 mi., its breadth from north to south varies from 35 to 7½ mi. The northern coast line is much indented. On the west the Gulf of Kisamos is formed by two narrow mountainous promontories, the western terminating in Cape Voux (ancient Corycus), the eastern in Cape Spatha; beyond the Bay of Canea (Kolpos Khanion) to the east, the rocky peninsula of Akrotiri shelters the magnificent natural harbour of Suda (Kolpos Soudhas, 8½ sq.mi.), the only completely protected anchorage for large vessels which the island affords. Farther east are the bays of Candia (Kolpos Irakliou) and Mallia (Kolpos Mallion), the deep Mirabella gulf (Kolpos Merabellou) and the Bay of Sitia (Limn Sitias). The south coast is less broken and possesses no natural harbours, the mountains in many parts rising almost like a wall from the sea.

The greater part of the island is occupied by ranges of mountains which form four principal groups. In the western portion rises the massive range of the Levka Ori (White mountains), directly overhanging the southern coast with spurs projecting toward the west and northwest (highest summit, Pachnes, 8,045 ft.). In the centre is the smaller, almost detached mass of Psiloriti culminating in the Stavros (8,058 ft.), the highest summit on the island. To the east are the Lasithi mountains with Afendis Khristos

(7,024 ft.) and farther east the mountains of Sitia with Thrifti Oros (4,757 ft.). The Asterusia (4,039 ft.) mountains separate the central plain of Mesara (Pedhias Mesaras) from the southern coast. The isolated peak of Iouktas (2,661 ft.), nearly due south of Iraklion (Candia), was regarded with veneration in antiquity as the burial place of Zeus. The principal groups of mountains are for the greater part of the year covered with snow, which remains in the deeper clefts throughout the summer; the intervals between them are filled by connecting chains which sometimes reach the height of 3,000 ft. The largest plain is that of Monofatsion and Mesara, a fertile tract extending between Mt. Psiloriti and the Asterusia range, about 15½ mi. in length and 8½ mi. in breadth. The smaller plain, or rather slope, adjoining Canea and the valley of Alikianou, through which the Platanias (ancient Iardanos) flows, is of great beauty and fertility. A peculiar feature is the level upland basins which furnish abundant pasturage during the summer months; the more notable are the Omalos in the Levka Ori (about 3,445 ft.) drained by subterranean outlets, Nida in Psiloriti (about 4,396 ft.) and the Lasithi plain (about 2,657 ft.), a more extensive area, on which are several villages. Also characteristic are the deep narrow ravines bordered by precipitous cliffs which traverse the mountainous districts; into some of these the daylight scarcely penetrates. Numerous large caves exist in the mountains; among them are the famous cave of Ida in Psiloriti the caves of Melidhonion in Milopotamos and Sarchu in Malevizon, which sheltered hundreds of refugees after the insurrection of 1866, and the cave of Dicte in Lasithi, which disputes with Ida the honour of being the birthplace of Zeus. The so-called Labyrinth, near the ruins of Gortyna, was a subterranean quarry from which the city was built. The principal rivers are the Ieros and the Anapodharis, which drain the plain of Mesara and enter the southern sea west and east respectively of the Asterusia range; the Platanias, which flows northward from the Levka Ori into the Bay of Canea; and the Milopotamos (ancient Oaxes) flowing northward from Psiloriti to the sea east of Rethimnon.

**3. Climate.**—In summer Crete lies in the path of the very regular etesian winds, which blow steadily from the north. The air is dry and hot, especially in the interior plains like that of Mesara, which do not experience the daily sea breeze.

In winter, by contrast, the winds are more tempestuous and variable. If the eastward-moving cyclones pass to the north of the island, they give rise to southerly winds, while if they pass to the south, they draw in winds from the Aegean. In either case

CANEA (GREEK, KHANIA), CAPITAL OF CRETE

TOMI SCHNEIDERS

RETHYMNON WITH THE PSILORITI (IDRI: ANCIENT IDA) MASSIF IN THE BACKGROUND

they cause rain or snow, and Crete receives almost all its precipitation in the torrential showers of the winter months, particularly between November and January. Iraklion has an average annual rainfall of 20 in., 5 in. more than Athens. Snow lies through the winter at altitudes above about 1,600 ft., but in general winter in Crete is much milder than at comparative altitudes on the mainland because of the tempering influence of the winds from the sea, and the average January temperature at Iraklion (54° F.) is 5° higher than that at Athens. The south coast in particular suffers from frequent gales in the winter season; the north wind descending from the mountains causes severe squalls which are a danger to navigation, while the southerly winds also often meet the exposed coast at gale force. If these last winds continue into late spring, they bring very hot and dry air from north Africa, which may damage the ripening crops.

The mountains are not only colder and wetter than the plains, but they also receive much more rain in summer, mainly from thunderstorms.

**4. Vegetation and Animal Life.**—The flora of Crete, as might be expected in view of its geological history, is similar to those of the Peloponnese and Asia Minor. It includes also a few Cyrenaican plants. The forests of Crete have almost completely disappeared as a result of reckless felling, overgrazing and soil erosion. The woods of wild cypress (*Cupressus sempervirens* var. *horizontalis*) of western Crete now only survive on the slopes of the Levka Ori, while the Aleppo pine forests, once common in the eastern districts, are represented by a few scattered copses, for example on the southern slopes of the Lasithi mountains. The largest remaining stand of holm oak (*Quercus ilex*) is on the eastern slopes of the Lasithi range, and on the lower hills by the southern coast the Spanish chestnut (*Castanea sativa*) is occasionally found.

Brushwood of carob or locust tree (*Ceratonia siliqua*), strawberry tree (*Arbutus unedo*), wild olive and juniper and, along the streams, of plane and willows is less common in Crete than the low shrubby communities of prickly plants like the burnet (*Potentilla spinosa*), broom (*Genista acanthoclada*) and rockrose (*Cistus villosus* var. *creticus*) which exudes labdanum (used in

perfume manufacture). Grassland is scarce, but there are numerous herbaceous plants such as pinks and milkworts, and such bulbous species as the asphodel.

Bones of the elephant and pigmy hippopotamus were found in geologically recent cave deposits, and the deer only became extinct in historic times. In the 1960s there were fewer than 20 species of mammal on the island, 9 of which were endemic. Of these species the largest is the *agrimi* or wild goat (*Capra aegagrus*) which is found in the Levka Ori and the Psiloriti mountains. There is also a Cretan variety of dog, a large variety of weasel and a light-coloured hare. The wildcat is found, along with the marten, badger and mouflon or wild sheep. There are no indigenous poisonous snakes or wolves on the island. (Wm. C. B.)

## II. ARCHAEOLOGY

The archaeological importance of Crete lies chiefly in its prehistoric remains, which have revealed the development in the island during the Aegean Bronze Age of a culture comparable in artistic and material achievement with the contemporary civiliza-

tions of Mesopotamia and Egypt. This Cretan culture extended in its maturity to the whole of Greece and exercised considerable influence in more distant regions of Europe. (See *AEGEAN CIVILIZATION*.) Ancient literary references to Crete as the source of many elements in Hellenic culture and religion had led several scholars to expect there the origins of the Mycenaean art which Heinrich Schliemann (*q.v.*) and others had discovered in mainland Greece in the second half of the 19th century, but the disturbed political condition of the island at that time was an obstacle to methodical excavation.

**1. Excavations.**—Schliemann visited Crete in 1886 and was attracted to Knossos where casual explorations had revealed the existence of large prehistoric buildings. But he was prevented from indulging his enthusiasm in the excavation of that complex site by administrative and personal objections. An Italian expedition supported by the Archaeological Institute of America had explored and excavated in southern districts of the island since 1884, but with no special interest in any particular period of antiquity.

The first investigator who worked in Crete with the purpose of defining its place in Aegean civilization was A. J. (later Sir Arthur) Evans (*q.v.*) of Oxford university. He made his first visit in 1894, in search of a class of seal stones engraved with pictographic characters which he had identified as Cretan, and in the same year he acquired ownership of part of the site of Knossos. But it was not until 1899, when the provisional Greek government was established, that he was able to complete the purchase and begin his excavation. In the same year in the southern plain (Mesara) the Italian expedition began the excavation of the palace of Phaistos. A smaller palace at Ayia Triada between Phaistos and the southern sea was also discovered and explored. The American Exploration society, affiliated with the University of Pennsylvania, sent an expedition in 1901, under Harriet Boyd of Smith college, which excavated town sites at Gournia and Vasiliki. The work was continued after 1905 by Richard Seager. With the support of U.S. universities and museums and of the American School of Classical Studies at Athens Seager excavated towns and tombs on

the islands of Mochlos (Mokhlos) and Psira in the Gulf of Mirabella and tombs at Pakhia Ammos on the isthmus of Ierapetra. Other important cemeteries on the two limestone hills of Sphoungaras and Vrokastro in the same district were explored by the American School. The British School of Archaeology at Athens excavated houses and tombs at Knossos, cave sanctuaries at Psikhro in Lasithi (ancient Dicte) and Kamares on Mt. Ida (Psilorit) and towns at Palaiokeastron and Zakros on the east coast. The French School at Athens excavated the third large palace known in Crete, at Mallia on the north coast east of Knossos. A small palace or large house west of Ida at Monastiraki was excavated by Germans during their military occupation of Crete in 1942.

The field work of the Greek authorities has been active and important, but the government has liberally permitted foreign workers to undertake the more extensive excavations, using its own resources mainly to deal with the numerous accidental finds of tombs or buildings and the rapid accumulation of material in the Cretan museum at Iraklion (Candia). The nucleus of that unique collection had been formed by the local archaeological society, the *Sylogos*, in the days of Turkish rule. The first Cretan ephor of antiquities and director of the museum that was built in 1908 was J. Khatsidakis, who had been president of the *Sylogos*. He excavated a large house at Tylissos, west of Knossos, and began the exploration of Mallia. His successor, S. Xanthoudides, excavated houses at Khamaizi and Nirou Khani and an important series of early tombs in the Mesara.

**2. Sites.**—The prehistoric sites explored are those of towns, royal palaces, large houses, sanctuaries and tombs. Towns are best represented at Gournia, Palaiokeastron, Psira, Mochlos and Vasiliki. The great palaces at Knossos, Phaistos and Mallia were centres of civic life, but continuous habitation in historical times has largely destroyed the prehistoric cities. The large buildings now isolated at Ayia Triada, Tilissos, Monastiraki and elsewhere may have been administrative centres of small communities, like that of Gournia, or religious establishments: not temples but priestly residences. Several such houses built in close proximity to the palace at Knossos indicate that these elaborate structures need not have been royal. The sanctuaries are either walled enclosures on hilltops, as at Mt. Iouktas near Knossos and Petsofa near Palaiokeastron, or mountain caves, of which the best known are those of Ida and Dicte. Most of these caves have produced evidence of Neolithic habitation; they were next used as communal burial places; and finally as receptacles for votive offerings to divine or chthonian powers. Later burials, communal and single, were made in built or dug tombs of great variety. There is no evidence of

cremation during the Bronze Age in Crete.

**3. Nomenclature and Chronology.**—In order to make the distinction between the original Cretan art and its derivative Mycenaean forms, which contained in their mature and later developments many mainland (Helladic) elements, Evans proposed the name Minoan for the Cretan Bronze Age. He defined three principal epochs, Early, Middle and Late Minoan, distinguished by the successive phases of decoration of pottery viewed as an index of artistic development. Each main epoch was divided into three numbered periods on the principle of the rise, maturity and decline of each ceramic style. The names of the nine periods are usually abbreviated to their initial letters and numbers, E.M. I, etc. Absolute chronology rests upon reciprocal contacts with Egypt, where dates are fairly well established.

The sequence and synchronisms of the prehistoric Cretan periods are as follows:

Crete	Egypt	Years a.c.
Neolithic	Pre- and protodynastic	c. 4000-3000
E.M. I	2nd-3rd dynasties	3000-2800
E.M. II	4th-6th dynasties	2800-2500
E.M. III	7th-11th dynasties	2500-2200
M.M. I	11th-12th dynasties	2200-2000
M.M. II	12th-13th dynasties	2000-1750
M.M. III	14th-17th dynasties	1750-1580
L.M. I	18th (to Tuthmose III) dynasty	1580-1475
L.M. II	18th (to Amenhotep III) dynasty	1475-1400
L.M. III	18th-19th dynasties	1400-1200
Sub-Minoan	20th-22nd dynasties	1200-1000

Closer study of the pottery and its stratification has made possible a further division of the M.M. and L.M. styles into earlier and later phases, M.M. Ia, M.M. Ib, etc., and in L.M. III three phases are recognized, a, b and c. It has also become evident that there were local variations in ceramic decoration and particularly that two styles which are characteristic of the periods M.M. II and L.M. II at Knossos were not produced at other centres. Some confusion arises from the use of the same names for the chronological periods, which must be fixed, and for the ceramic styles, which tend to be variable in time and place. It is desirable to keep the names that were originally applied to the pottery, as Vasiliki ware for the distinctive eastern fabric of E.M. II and III, Kamares ware for the Knossian polychrome style of M.M. I and II, the Palace style for that of L.M. II, and to name the periods only in dating the styles.

**4. Egyptian Contacts.**—Fragments of pre- or protodynastic stone vessels were found in a Late Neolithic stratum at Knossos. The technique of stone vases found in E.M. burials at Mochlos is manifestly derived from Egypt, and many of their shapes are imitations of those of the Old Kingdom. Signets of E.M. III are also imitations of Egyptian work, the models being seals and devices of the First Intermediate period. Scarabs of the 11th and 12th dynasties have been found in M.M. I burials. The inscribed base of a diorite statuette of the early 12th dynasty was found in a M.M. II stratum at Knossos, and M.M. II pottery has been found in Egypt in 12th-dynasty deposits at the Pyramid of El Lahun and Harageh and in a tomb at Abydos (al-'Arabat al-Madfun). An alabaster lid bearing the cartouche of the Hyksos Pharaoh Khyan was found in an early M.M. III context at Knossos. Wall paintings in Egyptian tombs of the early 18th dynasty show Minoan envoys bearing vessels of L.M. I forms.

TONI SCHNEIDERS  
 RUINS OF ST. TITUS AT GORTYNA

in the latest of these (tomb of Rekhmire, minister of Tuthmose III) the envoys wear the kilt which first appears at Knossos in frescoes of L.M. II. A seal of Tiy, queen of Amenhotep III, comes from an L.M. II tomb at Ayia Triada. Aegean pottery found in Egypt after that time seems to be of mainland (Mycenaean) style and fabric; the synchronisms with Crete are therefore indirect, but not less certain. Many shards of the Mycenaean style parallel to that of L.M. IIIa were found at Tell-el-Amarna in the city founded by Ikhnaton (Amenhotep IV) and abandoned after his death. Relations between the Aegean world and Egypt became hostile during the 19th dynasty and no material contacts with Crete are visible before the end of the Bronze Age, when a few beads and seals of the 20th–22nd dynasty types appear in Proto-geometric burials at Vrokastro.

**5. Origins and Development.**—The earliest Neolithic artifacts found in Crete are considerably advanced in character and indicate that their makers were immigrants. Since access to the island was easy from the east and south, and the Stone Age settlements were mainly in the eastern and central regions, it seems likely that the people came from the shores of Africa or Asia Minor or both. The first foreign material that is identifiable is obsidian in flakes and cores from the island of Melos; but the Cyclades seem not to have been inhabited at that time. Contact with Egypt, probably through Libya, is seen in fragments of stone vases found in the latest Neolithic strata at Knossos. The large knoll on which the palace stands is topped with about 24 feet of deposit from Stone Age habitation. The conjectural date of 4000 B.C. for the beginning of the Neolithic Age is based upon an estimate of about 1,000 years for the accumulation of so much refuse; the lower date is supplied by the Egyptian stone vases. Neolithic deposits elsewhere are mostly found in caves and rock shelters, but this does not mean that the Cretans of the Stone Age did not build houses. Stone footings of house walls are associated with a rock shelter at Magasa near Palaioastron, and complexes of rectangular rooms with fixed hearths were found below the Minoan court at Knossos. The Cretan material shares the general character of the Neolithic culture that was prevalent in coastal regions of Syria and Egypt. The earlier pottery is generally dark-faced, often decorated with modeled pellets punctuation or simple linear incision. Its development was technical rather than artistic, as better firing produced clear or mottled surfaces. There is no connection with the contemporary painted wares of mainland Greece. But steatopygous female figures and small animals modeled in stone or clay and implements of polished stone resemble those of all adjacent regions.

Artistic progress began toward the end of E.M. I with painted linear decoration in black glaze on a light clay surface. This period was the beginning of the Copper Age. Bronze was not made before M.M. I. But the use of metal and contact with its sources led to rapid advance in E.M. II and III. Most notable in E.M. II is a series of stone vases found at Mochlos. These reproduce some Egyptian shapes but their brightly coloured materials, veined marbles and mottled breccias are Cretan and obviously initiated the style of polychrome painting that is characteristic of M.M. the ceramic art. Short copper daggers appear in E.M. II and the production of engraved seals and gold jewelry was begun. In E.M. II the surfaces were sometimes covered with ferruginous pigment on which accidents of firing produced irregular variation (Vasiliki ware). In E.M. III the fired decoration was replaced by painted designs of white and red stripes and curves, including spiral coils. The most remarkable products of E.M. III are ivory and steatite signets carved in animal forms and engraved with devices which often imitate Egyptian patterns. Polychrome pottery painted with formal designs in red and white on the black glazed ground reached its highest point of development in M.M. I and II (Kamares style). That was also the time of the first Minoan writing, the hieroglyphic script.

The first elements of the palaces belong to M.M. I. The mound of Knossos was cleared of earlier buildings and its top was leveled for the central court. The new buildings were more or less isolated structures around the court. At the end of M.M. II there seems to have occurred one of the destructive earthquakes to which

Crete is still liable; destruction is visible on all sites and some were not reoccupied. But the damage gave opportunity for extensive reconstruction of the palaces, the final plans of which were mainly determined at the beginning of M.M. III. An apparently new feature was the addition of colonnades to the courts. The elaborate fresco paintings which belong to this period were not a new process but there are no earlier examples of the naturalistic style which was perfected in M.M. III. Its influence on the minor art of ceramic decoration is seen in the replacement of formal polychromy by white on black designs incorporating simple motifs drawn from floral and marine life. Human and animal figures were not admitted to the ceramic repertory but were freely exploited in fresco painting and seal engraving. The hieroglyphic symbols were replaced by a linear script in M.M. III.

At the end of the period there was another destructive earthquake, followed at most sites by rebuilding. This was the moment at which the arts and influence of Crete began to be extended to mainland Greece where they were further and strongly developed as Mycenaean. It is a remarkable and unexplained fact that there was no significant contact between Crete and the mainland before L.M. I, although the two cultures met in the midway island of Melos early in the M.M. period.

Most of the external details and internal decoration of the palaces date from L.M. I. A complete change of technique in ceramic painting seems to have been due to need for clearer expression in representing natural subjects, which were, however, still restricted to plant and marine life. The designs were painted in the black-glazed medium on the light-yellow surface of the clay, which was also lustrous. This was the technique of Mycenaean pottery in the Late Helladic periods of mainland Greece. Much of the pottery of L.M. II at Knossos was decorated in a formal and grandiose manner which is appropriately called the Palace style. Another peculiarity at Knossos in this period was the replacement of the first linear script (A) by an enlarged version (B). Script B has been found on numerous clay tablets, precisely similar to those of Knossos, at Pylos and Mycenae, and the language written with it has been recognized as Greek. (See *Scripts* below.) Knossos must therefore have passed into Hellenic control at least two generations before the destruction of what Evans called the "Last Palace" which occurred at the end of L.M. II (c. 1400). Since all the towns and palaces of Crete were destroyed or damaged by fire at the same time, it is evident that the destruction was caused by enemy action. The enemies could only have been the Mycenaean powers of mainland Greece, which did, in fact, replace the Minoans in Aegean relations with Egypt and Syria in L.M. III.

The general catastrophe did not destroy Minoan prosperity, but seems to have reduced Crete to a subordinate position in the Aegean world. A notable sequel, if not a consequence of the destruction, was the extension of settlement toward the west of the island in L.M. III. The only considerable western establishment that is known before that time is the M.M. house at Monastiraki. The palaces were not rebuilt nor fully reoccupied, but a curious feature was the installation of small and rather primitive religious shrines in most of them toward the end of L.M. III. The only new palatial building of L.M. III date was a large megaron of Mycenaean type imposed upon the Minoan ruins at Ayia Triada. The period of transition from the Bronze to the Iron Age is called Sub-Minoan. It was a time of stress and turmoil in the Aegean world, following the fall of the Hittite empire and the attacks made upon the Syrian and Egyptian coasts by the Peoples of the Sea. It was marked in Crete by retreat from coastal sites to mountain fastnesses and great loss of population. The new settlements were represented at Kavousi and Vrokastro, where buildings were few and poor, and burial excavations show the intrusion of fibulae and large pins indicating new fashions of dress, iron weapons and the funeral rite of cremation. No Aegean material of this period has been found in Egypt, but a few hieroglyphic seals and beads from Vrokastro may be as late as the 22nd dynasty.

**6. Palatial Architecture.**—Palaces and palatial houses are the most remarkable Minoan monuments; their magnificence may have been partly due to the fact that in the absence of temples they were centres of religious cult as well as of royal or civic ad-

TONI SCHNEIDERS

(ABOVE) VATS AND CISTS FOR STORAGE IN THE RUINED PALACE OF KNOSSOS (2000-1400 B.C.) (LEFT) HARBOUR AT IRAKLION (CANDIA) SHOWING FORTRESS BUILT DURING VENETIAN DOMINATION, 1210-1669

ministration. The most important palaces, at Knossos, Phaistos and Mallia, had the same general plan and similar architectural details. Their buildings surrounded large rectangular courts of practically identical shape and size. Their mean measurements were precisely those of the court at Phaistos, 56 by 25 yd. Two sides of the central court of Mallia, at least one at Phaistos and probably at Knossos were bordered with colonnades which seem to have been fenced with timber between the pillars. These provisions and the fixed dimensions suggest that the courts were intended for some common purpose, and it has been plausibly claimed on this and other evidence that they were the arenas of the bull-leaping performances, which certainly had religious significance. There was a monumental shrine in the centre of the west side of the Knossos court, and doubtless similar structures in the others. The irregularities of Cretan sites were ingeniously exploited by the architects and wide flights of steps leading from one level to another were designed as decorative features. The principal entrance to the palace at Phaistos was a flight of 12 steps 45 ft. wide. Similar long steps set at right angles to each other in the so-called theatral areas of the outer courts seemed to have served as stands or seats for spectators at public functions. A regular design in entrances from the courts to upper floors was a stepped porch with a central column.

**Knossos.**—The site at Knossos is a large knoll which slopes down sharply to the Kairatos (Katsaba) river on the east and to the deep bed of a tributary torrent on the south. When space was needed on the eastern slope for extension of the palace in M.M. II, the ground was cut down 25 ft. vertically and the domestic apartments were built in two stories below the central court and approached by a monumental staircase. These buildings were protected by their position from destruction by fire and earthquake and were filled up in the course of time by debris from the higher levels, which held their stone floors and steps in place until the excavators dug them out and replaced the original supporting timbers with steel and concrete. Each flight of stairs was carried by wooden columns standing on the stone balustrade of the flight below. These two stories and the four flights of the grand staircase leading down to them are unique examples of construction and design. Since the inner wall was necessarily windowless, being backed by solid earth, air and light were supplied to the staircase and adjoining rooms through small open courts or light wells. The large rooms opened on these through heavy colonnades, and their inner walls were pierced with wide doorways with jambs placed in the lines of the columns and recessed to conceal the doors when opened. This was a regular and effective feature of

internal planning. Interior columns were made of wood and were set on ornamental stone bases. Shafts have left impressions of their cylindrical or tapered shapes on earth or plaster in which they were subsequently embedded. They were also decorated with concave, convex or spiral flutes, which must have been applied in plaster.

The large series of open courts and terraced roofs presented drainage problems which were ingeniously met at Knossos by the construction of stone-built conduits and clay water pipes, which were also used for sanitation. Since there was no source of water on the palace hill, the flushing system could only have been effective in the rainy season, for a small part of the year, and the advanced ideas of sanitation that have been recognized there must have been backward in performance.

The administrative and ceremonial quarters at Knossos were on the west side of the central court. Most remarkable was the throne room, which still contains the high-backed gypsum chair of the king. Stone benches were built along the walls, which were decorated with a painted frieze of griffins. The room was connected with a sunken lustral area entered by two flights of steps with a columned balustrade like those of the great staircase. The lustral areas existed in all the palaces and in some of the large houses. They were at first thought to be baths, but since they were found to be lined with gypsum, which is not waterproof, and had no provision for drainage, they must have served some other purpose, probably lustration with oil or water in religious rites. The ritual may have been directed to the propitiation of divine powers controlling earthquakes, a cult that is reflected also in pillar crypts, cellars or basement rooms containing main supporting piers over which were the columns of the upper rooms. Some of the piers were marked with the sign of the double axe and some of the crypts contained sacred furniture. The administrative quarters of all the palaces were marked by series of long narrow basements which were evidently built and used as magazines for stores and treasure. There were 22 of these in the west wing at Knossos. Some still contain large earthenware jars for corn or wine or oil, and cists sunk in the stone floors and sometimes lined with lead retained fragments of gold objects that had been secured in them. The walls of the long corridor which led to this part of the palace from the southwest entrance were painted in the last period of Minoan grandeur (L.M. II, to which the throne room also belonged) with a processional frieze of many life-size figures. The well-known "Cupbearer," one of the first things found at Knossos, was one of these.

The approach to the palace from the south was carried up the

steep slope of the torrent bed in a long stairway with a roof supported on columns. The road of which this was the northern end led across the island to Phaistos and a port on the southern sea at Komo, through which traffic passed with Libya and Egypt. At the Knossian end was an elaborately built inn or resthouse (the "Caravanserai"), which was amply supplied with water for men and beasts and decorated with fresco paintings. The road was carried along the edge of the ravine on a massive viaduct of which the stepped piers remain. Several other buildings must have been dependencies of the palace. The largest, the Little Palace, and the Royal Villa on the bank of the Kairatos seem to have served religious uses; others were merely residences, but were built in palatial style. (See also PRE-HELLENIC ARCHITECTURE: *Minoan Crete*.)

**7. Minoan Towns.**—The best example of these is at Gournia. It lies on a small hill in a valley near the sea, but was not a seaport and may not have been so near the sea in ancient times. Several other towns in eastern Crete, at Vasiliki, Palaioastron, Zakros, Mochlos and Psira, have been partially destroyed by coastal subsidence or are only partly excavated. Their houses and building methods were similar to those at Gournia, though the plans were complicated there by the steep slopes on which the town was built. The remains show no signs of formal planning. Rooms were rectangular but various in size and number and had the appearance of complexes built or enlarged as space or other means allowed. The walls were constructed with small stones laid in clay or sun-dried bricks on stone footings and were stiffened and tied with wooden posts and beams. Internal surfaces were smoothed with hard plaster which was painted in plain colours. The richer houses doubtless had figured frescoes. A fragment of painted plaster relief comes from Psira, but none was found at Gournia. Roofs were probably flat and made of clay rolled hard over reeds and joists. The outward appearance of ordinary town houses on the site is represented in a series of coloured faience plaques from Knossos. These show small buildings of two or three stories marked with squares or bands or disks as if to distinguish construction in cut stone from brick or rubble reinforced with beams; the disks are the beam ends. Windows were few and mostly in the upper floors; the roofs were flat. At Gournia the cross streets are stepped in many places, climbing the slopes with the houses, and the main streets leading through the town were not more than five feet wide. Streets at Palaioastron, a larger seaport town, were wider, and all were paved with stone. The highest point at Gournia was occupied by the palace, a direct though modest imitation of those in the royal cities. It covered about 12 times the space of the ordinary town house. The whole town occupied about the same area (6 ac.) as the palace at Knossos.

**8. Sanctuaries.**—The ritual furniture found at Knossos and Mallia shows that the palaces were centres of religious cult. A fresco painting at Knossos with a picture of an edifice or frontage composed of baetyl pillars standing between sacred horns is believed to represent a shrine which stood on the west side of the central court. A furnished shrine belonging to the late reoccupation period (L.M. IIIb) was found intact in the palace. The only public sanctuaries that have been found are in walled enclosures on hilltops and in mountain caves. Sacred groves left no material records, but such woodland places of worship are shown in seal engravings. A gold ring signet shows a woman praying at a tall post to which a young god descends in response to the prayer. Minoan deities are represented in the forms and dress of men and women, and it is not always possible to distinguish between human and divine figures, nor can it be known if the latter represent a single god and goddess in various aspects or several of each sex. The hilltop sanctuaries at Iouktas and Petsofa contained ashes from sacrificial or other fires and votive offerings of pottery vessels and human and animal figures modeled in clay. Numerous caves which had served for habitation in the Stone Age and for burials in E.M. times were subsequently used for deposits of votive offerings, fine pottery at Kamares on Mt. Ida, small bronze objects in the cave of Dicte, bronze swords and votive axes at Arkalokhori. The large cave of Ida, celebrated in historical times as the birthplace of Zeus, does not seem to have been a sanctuary until the last Minoan period.

**9. Tombs.**—Cave burials were succeeded in E.M. times by communal burial in large stone-built enclosures which may or may not have been roofed. In the east of Crete they were rectangular, in the southern district of the Mesara plain, circular. These were at first believed to be the lower courses of *tholos* or beehive tombs such as were built much later in mainland Greece. But the walls, so far as they are preserved, are vertical, and their construction was not solid enough to support a heavy dome; they may have had thatched roofs. Valuable offerings were buried with the dead: ivory and stone signets, gold jewels and copper weapons. The brilliant stone vases of Mochlos came from E.M. tombs. Single burials in earthenware coffins or large inverted jars are found in E.M. and M.M. graves, but communal burial or votive offerings at such burial places persisted into M.M. times. Next come the chamber tombs, artificial caves cut in soft rock on hillsides. These seem to have been family burial places, and since they were easily accessible and repeatedly used, valuable tomb furniture is seldom found in them. Transition from the rock-cut chamber to the built tomb of masonry was easy and attractive in an age of monumental architecture; but there were probably not many of these. A magnificent example was the so-called royal tomb at Isopata near Knossos, which was destroyed during World War II. It consisted of a forehall and an inner chamber built underground but roofed with a keel or barrel vault which would have risen above ground and was probably covered with a mound. The latest burial was in L.M. II, but the structure seems to have belonged to L.M. I. The temple tomb at Knossos, the last discovery made there by Evans, must have been a royal tomb. It was an elaborate two-storied structure, mainly above ground, leading to a rock-cut burial chamber. The plan was unique in the Minoan world. Although the architecture is Minoan, the idea of deification or worship which it suggests may have been adopted from Egypt or Caria. Shaft graves covered with stone slabs were frequent at Knossos in L.M. I and II, but burial in earthenware chests or baths in chamber tombs was the usual L.M. practice. Built beehive tombs with burials earlier than the middle of L.M. III were not found in Crete until the mid-20th century and those were not of the normal mainland form but had square chambers under circular vaults. But an elaborate *tholos* of earlier date and regular Mycenaean form was discovered at Knossos in 1955. It had been constantly re-used in L.M. times and there were no identifiable remains of the original interment. The structure, however, is certainly no later than the beginning of L.M. I and perhaps as early as the end of M.M. III. Burials of the transitional Sub-Minoan period are best known from Kavousi, Mouliana and Vrokastro. At Kavousi the funeral rite was inhumation, at Vrokastro cremation, and tombs in both cemeteries produced fibulae and iron weapons. A small built *tholos* at Mouliana, east of Mirabella, probably belonging to one family, contained two burials, an earlier inhumation with bronze fibulae and weapons and a slightly later cremation with remains of an iron sword.

**10. Painting.**—The master art of Minoan Crete was fresco painting. Its influence is visible in the pictorial character and content of the minor arts of ceramic decoration, embossed metal-work and seal engraving. Interior wall surfaces were necessarily plastered in rubble-built houses; some red-painted fragments at Vasiliki belonged to E.M. II. But the material was too fragile to survive rebuilding to any considerable extent. The later frescoes that have been found had fallen from standing walls and are extremely fragmentary; the pieces seldom illustrate more than details of the work. The earliest designs seem to have been painted reproductions of structural elements covered by the plaster, grained timber beams and rows of coloured disks representing ends of logs. The polished stone veneers of palatial walls were also imitated in paint, as coloured veins of marbles were reproduced on M.M. polychrome pottery. Some figured plaster fragments of M.M. II date at Knossos are printed with impressions of a sponge, and whether these were meant to reproduce mottled stone or were regarded as decorative devices in themselves is not clear. These formal patterns were used in later paintings for dadoes or frames of pictorial scenes. The earliest pictures that exist belong to M.M. III, but their mature development shows that they were

TONI SCHNEIDERS

LARGE EARTHENWARE JAR (PITHOS) AMONG RUINED FOUNDATIONS OF THE MINOAN PALACE AT MALLIA

not the first of their kind. They were mostly landscapes and seascapes enlivened with animals and fishes. A cat stalking a pheasant and deer leaping among rocks and flowers come from Ayia Triada. Fragments from a house at Knossos show blue monkeys prowling over rocks, a bird in flight and apparently a jet of water in a garden. Scenes from marine life, such as a picture of brightly coloured fish swimming among rocks and sea urchins from the domestic apartments at Knossos, are highly naturalistic. The handling of human subjects was realistic and vivid. Most notable is a series of miniature frescoes from Knossos illustrating public festivals. One of them depicts elaborately dressed ladies engaged in lively conversation beside a pillar shrine, around which a crowd of people is represented by massed heads drawn in outline and enlivened with white eyes and necklets and some waving arms. The only subjects from the living world that were stylized decoratively and thus adopted by ceramic painters were creatures of the sea: a large pottery jar from Pakhia Ammos has painted pebbles at its foot, swimming dolphins on the body and spray and bubbles at the top. Men and animals had no place in ceramic painting until the latest Minoan times; birds began to appear in L.M. II, perhaps as Mycenaean innovations. The marine designs characteristic of L.M. II pottery were not pictures but patterns. They were sometimes based on the single figure of the octopus, sometimes formed with grouped nautilus and shells, rocks and seaweed. The Knossian Palace style of that period preferred large formal schemes of flowers modeled on the Egyptian papyrus. These and the architectural elements in the designs mark them as excerpts from wall paintings. Egyptian or Mycenaean influence seems also to be reflected in the large processional scenes that were the latest decorations at Knossos. The long corridor leading from the southwest entrances to the palace was painted with large numbers of life-size figures, boys and girls, priestesses or goddesses, carrying or receiving ritual instruments.

No L.M. III wall paintings are known in Crete, but to the beginning of that period or the end of L.M. II belongs a painted stone sarcophagus which was found at Ayia Triada. This bears detailed pictures of a sacrifice performed at the grave of a noted man. The ritual consists of libations of blood drawn from the throat of a slaughtered bull and offerings carried to king or hero

who stands in graveclothes outside his tomb. It is an instructive illustration of the personal worship that is indicated in the construction of the temple tomb.

**11. Sculpture and Modeling.**—Sculpture in the round was not an art in which the Minoans excelled, unless it was on a small scale and in material such as ivory and steatite which could be carved easily in fine detail. This technique is represented at its best by the ivory statuette of a goddess holding gold snakes (in the Boston [Mass.] Museum of Fine Arts), and by the figure of a leaping boy from Knossos. No statues have been found, but there are many statuettes in clay, faience and bronze. They provide the earliest records of Minoan dress, men's loincloths worn with tight belts and women's long voluminous skirts and bodices exposing the breasts. In L.M. I or II a short kilt was adopted by the men (see *DRESS: The Aegean*). Lively but summary clay figures came from the M.M. I sanctuary at Petsofa. Coloured faience statuettes of goddesses or priestesses, furniture of an

M.M. III shrine, were found at Knossos. Cast bronzes are later, but their technique is generally imperfect and the detail coarse. One of the most successful is the figure of a man with arms raised in prayer (in the museum of Leiden, Netherlands). Animal subjects, as in painting, were more congenial to the Minoan artist. A magnificent bull's head in black steatite comes from the Little Palace at Knossos, and there are similar ritual vessels in alabaster and silver. Large plaster friezes of bulls among olive trees decorated the northern entrance to the palace. But the masterpieces of sculpture in relief are three small black steatite vases from Ayia Triada which bear ritual scenes, of boxing and bullfighting a sacrificial offering to the king, and a procession of 27 people engaged in an agricultural ceremony. This exquisite miniature work, of which there are several fragmentary examples, was closely related to reliefs in metal.

**12. Metalwork.**—The finest examples of Minoan metalwork are a pair of embossed gold cups which were found in the Vaphio tomb in Laconia, and bronze dagger blades inlaid with pictorial designs in gold and silver from the shaft graves at Mycenae. The scenes on the cups are contrasted episodes in the handling of wild and domesticated cattle. Few rich graves have been found in Crete and inhabited sites do not retain much treasure. But some large bowls and ewers of bronze and silver, extremely well designed and ornamented with formal patterns, have come from houses and tombs at Knossos. Shapes of early pottery vessels are largely metallic in origin, but very few examples of the prototypes have survived. The earliest and best is an elegant silver goblet from Gournia. Simple gold jewelry was found in E.M. burials at Mochlos; it is composed of flowers and leaves cut from foil and linked together with delicate wire chains. A remarkable M.M. I gold jewel from Mallia has the form of two bees holding a finely granulated disk, and there are other early examples of granulation and filigree. An exceptionally large bronze sword with gold-plated hilt and crystal pommel was found in the palace at Mallia and has been assigned to M.M. I; but weapons of early date are rarely found for the same reason that jewelry is scarce, because successive burials in chamber tombs gave opportunity for removal of valuable furniture. Most tombs produced a few gold beads that escaped the activities of the removers. These were often in the

shapes of nautilus or shells or flowers; strings of such beads are represented in paintings and reliefs, which also showed that much jewelry was worn. The king on the small steatite vase from Ayia Triada has bracelets, armlets and a triple necklace and carries a dagger in his belt.

Shaft graves at Knossos of L.M. II date have produced many long swords with embossed gold-plated hilts like those from the shaft graves at Mycenae. Gold ring signets have also come from tombs. They usually have long oval bezels on which a device is engraved and broad beaded or ribbed hoops. These seem to be too small for a finger and were probably designed to be worn as pendants. Most of the engraved designs are pictorial, but a ring from Knossos has a circular bezel engraved spirally with linear script.

**13. Seals.**—The first Minoan seals were Egyptian in material and design, being made of ivory and engraved with linear patterns, lattices, scrolls or spiral coils. Some of them can be dated in E.M. II but the great age of seal engraving began in E.M. III, when the soft native stone, steatite, came into general use beside imported ivory. The earliest forms were cylinders, not like the oriental roll seals but short sections of tusk with devices cut on the two circular ends. A pointed section made a stamp seal with a handle, which was also carved in natural forms of seated monkeys, lions, birds or heads of animals. Simple pictorial subjects were among the devices of that time; disks and prism beads were added to the shapes.

The three- or four-sided prism was the form adopted for the new hieroglyphic inscriptions of M.M. I; the Egyptian scarab was known but not chosen for this purpose. Hard stones, carnelian, agate, crystal, chalcedony or jasper, came into use for hieroglyphic seals, and pictorial devices, usually representing animals, were frequent in M.M. II. In M.M. III, which was also the great age of painting, humans and other animals were freely illustrated, and the displacement of hieroglyphs by linear script, which was not suitable for seals, left an open field for pictorial development. New forms were invented for these larger pictures; flattened cylinders, oval amygdaloids and circular lentoids replaced the disks and prisms. Many of the engraved devices are known from large deposits of stamped clay sealings, which seem to have been made for official reference, at Knossos, Ayia Triada and Zakros. Those from Zakros are largely fantastic or comic in character, with figures or faces of imps and bogies. They may be related to a class of amuletic gems which were engraved with summary representations of sacred horns and branches, gabled doorways or similar structures. Gold and silver stamp seals were replaced in M.M. III and later by ring signets with large bezels of amygdaloid shape. Most of those that have been found belong to L.M. I and were engraved with elaborate cult scenes. The lentoid stone tended to displace the amygdaloid in this period and the next, apparently because its circular field invited the contorted attitudes in which the Minoan artist tended to pose his living subjects. These are the common motives of L.M. III gems: cows suckling calves, lions or men struggling with bulls or animals writhing by themselves. A few cylinder seals which belonged to the end of this last period were probably Mycenaean innovations, for the oriental roll cylinder, like the Egyptian scarab, was a form that the Minoans had known and rejected.

**14. Scripts.**—The hieroglyphic script, which appears first on M.M. I seal stones, is Egyptian in character and con-

tains a few Egyptian signs, but seems to be otherwise an independent system. Most of the signs are summary representations of common objects, human figures and limbs, animals, birds, insects, tools, weapons and the like. Their interpretation is uncertain. A clay disk impressed on both sides with pictographic signs in spiral sequence was found in an M.M. III context at Phaistos, but this is generally believed to be from Asia Minor. The Minoan hieroglyphs were incised on clay bars and labels in M.M. II as well as being cut on seal stones. This development was completed in M.M. III, when a linear script appears on small rectangular clay tablets and round labels. This was incised with a sharp point; it also was written in ink and cut in stone. About a third of the known characters are derivatives from the hieroglyphs. This script, now known as Linear A, was in general use, but comparatively few tablets have been found. Most of them (about 150) come from Ayia Triada and about 10 from Knossos. The duration of the A script has not been everywhere determined, but it was superseded at Knossos in L.M. II by the Linear B script. This is similarly incised on thin clay tablets, which have been found in large numbers (nearly 2,000) in the palace but not elsewhere in Crete. Determinative signs which accompany the texts, representing men, women, horses, chariots, weapons and other commodities, and numerical notations indicate that the documents were mostly inventories. Script B is evidently an enlargement of A and about half the known characters of A are found in B. Both scripts are syllabic. When these tablets were excavated at Knossos no similar documents were known in mainland Greece, but after 1939 more than 1,000 had been found at Pylos and Mycenae in chronological contexts which are not earlier than the end of the 13th century (L.M. IIIb). The recognition of verbal inflections in B which are not found in A points to a difference of language, and that of the B (Mycenaean) texts has been identified as Greek. It is surprising to find the Greek language in Crete so early as the end of the 15th century, but it would be surprising not to find it on the mainland as late as the end of the 13th. Interpretation of the texts is not a straightforward process. The script comprises some 90 syllabic characters and 120 ideograms. The characters are first transcribed into alphabetic syllables in accordance with a generally but not wholly accepted scheme of phonetic values. The syllables are next combined in actual or possible Greek words, which are separated in the texts by interpuncts. The words are finally translated in contexts which are often indicated by ideograms and numerical notations. Results so far produced are therefore cautiously received by scholars who appreciate the hazards of phonetic and philologic equations. No progress had been made (1960s) in the interpretation of Script

A. As current records and not archives the Linear B documents may be expected to belong to the latest years of the buildings in which they were found. But there were two destructions of the last palace at Knossos, at the beginning and the end of L.M. III respectively.

Some of the tablets were associated there with the earlier occupation, but others, particularly in the western magazines were recognized as having fallen from upper floors, and could not be dated stratigraphically. These may have belonged to the regular, if partial, reoccupation indicated by the shrine of the dove goddess and other late structural elements. The Minoan language had not been determined, but place names and certain groups of words in the later Greek vocabulary suggest connections with Asia Minor. Six inscriptions on stone in Greek letters and an unknown language, found at Praisos, and one from Dreros (near Neapolis), seem to record the surviving native speech in eastern Crete in the 5th and 4th centuries. See MINOAN LINEAR SCRIPTS.

**15. Later Periods.**—The two or three centuries which followed the destruction of Mycenaean culture in Greece are marked in Crete by evident loss of population and desertion of urban sites, particularly of coastal towns. Settlements and several shrines furnished with terra-cotta images have been found in Lasithi and other mountain districts, where re-used Mycenaean tombs contain the pottery with linear decoration which is known as Protogeometric, together with fibulae and iron weapons. The funeral rite was commonly cremation. In the period which is known from the character of its ceramic decoration as Geometric, the archaeology of Crete presents no distinctive features. But toward the end of that time the island took a prominent place in the renewal of contacts with Magna Graecia and Asia Minor. The population was replenished, probably by immigrants from Greece, and several large cities were founded in the west. This move explains the displacement of the cave of Dicte by that of Ida as the principal religious sanctuary. Among the offerings deposited there was a series of bronze shields and disks embossed and engraved with designs of oriental character but apparently of local technique. These are generally dated to the 8th century. Statuettes made of bronze plates hammered over a wooden core have been found in a Geometric temple at Dreros. A later temple at Prinias in central Crete was decorated with stone reliefs and figures in the round which belong to the 7th century, and statues of the same style found in mainland Greece were evidently derived from Crete.

### III. HISTORY

**1. Ancient History.**—In historical times nothing remained of the Minoan civilization except a tradition that the first thalassocracy or sea power was that of a Cretan king Minos (q.v.). The island played no part in Greek history commensurate with its size. It was not involved in the Greco-Persian or Peloponnesian Wars.

It is mentioned in the *Odyssey* of Homer with respect as the island of a hundred cities, and with some curiosity in regard to its inhabitants, who are enumerated as Dorians, Achaeans, Pelasgians (q.v.), Cydonians and Eteocretans. The general sense of these statements is clear and they were doubtless true in the poet's time (8th or 7th century B.C.). The dominant element in the population was then and later Dorian, but there is no archaeological or historical evidence for the time or manner of their arrival. Later Greek interest was attracted by the political and social constitution of the Cretans, who seemed to be more Spartan than the Spartans. As in Laconia, the people were distinguished as full citizens, unprivileged citizens, serfs and slaves. The full citizens were the Dorians, the unprivileged apparently the Achaeans and the serfs the Eteocretans or Minoans. The great inscription of Gortyna (q.v.) defines these classes. The system of communal life and military education were similar to those of Sparta.

Hellenic building styles appear in houses and temples in the 8th century, and revival of the coastal towns and maritime commerce was followed by the reception of Oriental influences which gave Crete for a time the foremost place in artistic progress. This was the time of the famous hundred cities, which were well

equipped with temples, agoras and civil buildings. Elaborate polychrome pottery, embossed metalwork and monumental statues of stone and hammered bronze were produced and exported abundantly. There were the works which formed the earliest archaic arts of Greece and were later attributed to the legendary master craftsman Daedalus (q.v.). But as in Minoan times, Crete having led the way was displaced by the greater resources of the mainland. It may be that the Dorian constitution which attracted Greek philosophers and historians did not encourage artistic and commercial progress. In historical times the strongly fortified cities were largely engaged in attacking one another, perhaps because of the confederacies which Cretans favoured and of which the most powerful states, Knossos, Lyttos or Gortyna, from time to time disputed the leadership. A consequence of these rivalries was that as Cretan men sought employment abroad as archers or other mercenary soldiers, the cities contracted short-lived alliances with dominant Hellenistic powers, and became notorious as providers of formidable corsairs. It was this proclivity which brought the island ultimately into disastrous collision with Rome. A final ill-advised alliance of the confederacy with Mithradates VI Eupator of Pontus was followed after his defeat by the invasion of Quintus Caecilius Metellus Creticus, and Crete was annexed by the Romans in 67 B.C. The Italian excavations at Gortyna, the administrative capital, revealed a model Roman city, with its conventional provision of temples and civic buildings, circus, amphitheatre and baths. As a favoured province securing the seaways to Syria, Egypt and Cyrene, Crete enjoyed a long period of unbroken peace and prosperity, until the beginning of Arab attacks on the southern borders of the Byzantine empire. (E. J. F.)

**2. Medieval Period.**—In A.D. 826 Crete fell into the hands of Arabs exiled from Spain. Thereafter it became a formidable nest of pirates and a great slave mart; it defied all the efforts of the Byzantine sovereigns to recover it till 960, when it was reconquered by Nicephorus II Phocas. After the capture of Constantinople during the fourth crusade by the Latins in 1204, Crete was allotted to Boniface, marquis of Montferrat, but was sold by him to the Venetians, to whom it continued subject for more than four centuries.

Under the Venetian government Candia (Iraklion, q.v.), a fortress originally built by the Arabs, and called by them Khandax, became the seat of government and capital of the island, to which it gave its name. The Venetian administration secured the island external tranquillity, and did much to provide material prosperity and encourage commerce and industry: under it Crete was probably more prosperous than at any other time. But the system was arbitrary and oppressive, and gave rise to many insurrections. Comte Pierre Antoine Daru in his *Histoire de Venise* (1819) mentions 14 between the years 1207 and 1365, the most important being that of 1361-64, when the Venetian colonists rose against the republic. Disappointed in the hope of a Genoese occupation the Cretans turned to the Turks.

**3. Turkish Domination.**—The Turks made no serious attempt to conquer the island until 1645; but in that year they landed an army of 50,000 men and soon reduced Candia. Rethimnon fell the following year, and in 1648 the Turks laid siege to Candia. After a siege of more than 20 years the city surrendered in Sept. 1669, and its fall was followed by the submission of the island. Venice was allowed to retain possession of Grabusa (Cape Vouna) Suda (Soudha) and Spinalonga on the north, but in 1692 Grabusa and in 1715 the other two strongholds fell to the Turks, and the island was finally lost to Venice.

Under Ottoman rule many of the Cretans embraced Islam, and thus secured the chief share in the administration of the island. But this did not benefit the population, and in 1837 Crete was considered the worst governed province of the Turkish empire. In 1770 an abortive attempt at revolt, the hero of which was "Master" John, a Sfakiot chief, was repressed with great cruelty. In 1813 the ruthless severity of the governor general, Haji Osman, who obtained the co-operation of the Christians, broke the power of the janizaries; but after Osman had fallen a victim to the suspicions of the sultan, Crete again came under their control. When

in 1821 the revolution broke out in continental Greece, the Cretans, headed by the Sfakiots, revolted and occupied all the open country, while the Turks and Muslims took refuge in the fortified cities. The island was reduced to submission in 1824 by Mohammed Ali, pasha of Egypt, whose help the sultan had asked. The allied powers (France, Great Britain and Russia) decided that Crete should not be included among the islands annexed to the kingdom of Greece; but obtained from the Turkish sultan Mahmud II its cession to Egypt, which was confirmed by a firman of Dec. 20, 1832. This change of masters brought some relief to the Cretans; the enlightened government (1832-52) of Mustafa Pasha, an Albanian like Mohammed Ali, who encouraged agriculture, improved the roads, introduced an Albanian police and put down brigandage, has been called the "golden age" of Crete.

In 1840 Crete was taken from Mohammed Ali and replaced under the dominion of the Turks, but Mustafa retained his governorship until appointed grand vizier in 1852. In Feb. 1856 an insurrection broke out as a result of the violation of the provisions of an imperial decree whereby liberty of conscience and equal rights and privileges with Muslims had been conferred upon Christians. The promised concessions were confirmed in July 1858, but again repudiated. A petition to the sultan in 1864 elicited only an injunction to obedience. A general insurrection which broke out in 1866 was put down with great severity, but the organic statute granted by the sultan in 1868 brought some reforms and a kind of constitutional government.

*Constitutional Experiments.*—Under this instrument which was afterward proposed, under article xxiii of the treaty, at the Congress of Berlin (*q.v.*), as a basis for reforms in other parts of the Ottoman empire, various privileges already acquired by the Christian population were confirmed; a representative general council was brought into existence, composed of deputies from every district; mixed tribunals were introduced, together with a highly elaborate administrative system, under which all the more important functionaries, Christian and Muslim, were provided with an assessor of the opposite creed. The new constitution, however, proved costly and unworkable, and failed to satisfy either section of the population. In 1878 the Greek government, finding Hellenic aspirations ignored by the treaty of San Stefano, gave the signal for agitation in the island. An insurrection followed, accompanied by barbarities on both sides. Eventually the Cretan chiefs invoked the mediation of Great Britain, which Turkey, exhausted by its struggle with Russia, accepted, and the pact of Halepa was drawn up in 1878 under the auspices of the British consul and Adossides Pasha, both of whom enjoyed the confidence of the Cretan population. The privileges conferred by the organic statute were confirmed; the judicial and administrative systems maintained; the judges were declared independent of the executive, and an assembly composed of 49 Christians and 31 Muslim deputies took the place of the former general council. The ensuing party government was a mere scramble for office and its rewards. In 1889 a crisis occurred, when the "conservative" leaders, finding themselves in a minority, took up arms and withdrew to the mountains. The latent fanaticism of both creeds was aroused, and the island again became a scene of devastation. The Porte seized the occasion to proclaim martial law and abrogate many important provisions of the Halepa pact. The Christians boycotted the elections under the new system, and for the next five years Crete was governed by a succession of Muslim valis; the deficit in the budget increased, the *gendarmerie*, which received no pay, became insubordinate, and crime multiplied. In 1894 the Porte, at the instance of the powers, nominated a Christian, Karatheodory Pasha, to the governorship, and the Christians agreed to take part in the assembly which soon afterward was convoked; no steps, however, were taken to remedy the financial situation. The refusal of the Porte to refund considerable sums illegally diverted from the Cretan treasury, or even to sanction a loan to meet immediate requirements, caused great exasperation, which was increased by the recall of Karatheodory (March 1895). Before that event an *Epitrope*, or "committee of reform," had appeared in the mountains. The *Epitrope* was at first nothing more than a handful of discontented politicians, but its membership swelled rapidly, and

in April 1896 it invested the garrison town of Vamos. Civil war began. Serious disturbances broke out at Canea (Khania) on May 24 and were only quelled by the arrival of foreign warships. Despite the intervention of the foreign consuls, the sultan proceeded to crush the rising by force. The resulting devastation, and the excitement it aroused in Greece, quickened the energies of the powers. Austria proposed an international blockade of the island, but Great Britain rejected this. At the representations of the powers, the sultan restored the pact of Halepa, the troops were withdrawn from the interior, financial aid was promised, a Christian governor general was appointed, the assembly was summoned and an imperial commissioner was dispatched to negotiate an arrangement. The Christian leaders proposed a moderate scheme of reforms, based on the Halepa pact, which, with a few exceptions, was approved by the powers and eventually sanctioned by the sultan.

*Revolt of 1897.*—On Sept. 4, 1896, the assembly formally accepted the new constitution and declared its gratitude to the powers. The Muslim leaders acquiesced in the arrangement, which the powers undertook to guarantee. It soon became evident, however, that the Porte was endeavouring to obstruct the execution of the reforms. The indignation of the Christians increased, a state of insecurity prevailed and the Muslim peasants refused to return to their homes. Hitherto the Greek government had loyally co-operated with the powers in their Cretan policy, but toward the close of the year a secret society known as the *Ethnike Etairia* began to arrogate to itself the direction of Greek foreign policy. Its aim was war with Turkey with a view to the acquisition of Macedonia, and it found ready allies in the Cretan Christians. Emissaries of the society appeared in Crete, large consignments of arms were landed and at the beginning of 1897 the island was practically in a state of insurrection. On Jan. 21 the Greek fleet was mobilized. A series of conflicts took place at Canea on Feb. 4; the Turkish troops fired on the Christians, a conflagration broke out in the town and thousands of Christians took refuge on the foreign warships. The Greek government now dispatched an ironclad and a cruiser to Canea, which were followed a few days later by a torpedo flotilla commanded by Prince George. The prince soon retired to Melos, but on the night of Feb. 4 a Greek force landed at Kolimbari, near Canea, and its commander, Colonel Vassos, proclaimed the occupation of the island in the name of King George. This move caused immense excitement among the Christian population, who indulged in terrible massacres of the Muslim peasantry. The powers, however, occupied Canea, and afterward Iraklion and other towns, blockaded the coast and bombarded the insurgents' position. They then presented collective notes to the Turkish and Greek governments announcing their decision that: (1) Crete could in no case in present circumstances be annexed to Greece; (2) in view of the delays caused by Turkey in the application of the reforms Crete should be endowed with an effective autonomous administration under the suzerainty of the sultan.

Cretan autonomy was proclaimed March 20, the Greek force left on May 9 and the insurgent assembly, under its president, Ioannis Sphakianakis, co-operated with the international commanders to maintain order. After Germany and Austria had withdrawn from the European concert (April 1898) the remaining powers divided the island into four departments, which they severally undertook to administer. The last Turkish soldiers left the island on Nov. 14, 1898.

*4. Union With Greece.*—On Nov. 26 the powers nominated Prince George of Greece as high commissioner for three years. He landed on Dec. 21. Order prevailed, but the Muslims, reduced to great distress by the prolonged insurrection, emigrated in large numbers. On April 27, 1899, a new autonomous constitution was voted by a constituent assembly, and in the following June, Cretan officials took over the local administration. Prince George's appointment was prolonged in 1901 and his extensive powers increased. The arbitrary methods of government awoke strong opposition, led by Eleutherios Venizelos, who had played an important part in the insurrection, but had been dismissed from his post of councillor in 1901. In March 1905 Venizelos, with the

moral support of Sphakianakis, led a revolt at Theriso in the Levka Ori and proclaimed the union of the island with Greece, and this example was speedily followed by the assembly at Canea. The powers, however, reiterated their decision to maintain the *status quo*, and increased their military and naval forces; the Greek flag was hauled down at Canea and Iraklion, and some desultory engagements with the insurgents took place, the international troops co-operating with the local *gendarmérie*. In the autumn Venizelos and his followers, having obtained an amnesty, laid down their arms. On July 25, 1906, the powers announced a series of reforms, including the reorganization of the *gendarmérie* and militia under Greek officers as a preliminary to the eventual withdrawal of the international troops, and the extension to Crete of the system of financial control established in Greece. On Sept. 25 Prince George left the island. His successor, Alexandros Zaïmis, a former and later prime minister of Greece, arrived in Crete on Oct. 1.

On Feb. 22, 1907, Zaïmis, as high commissioner, took the oath to the new constitution elaborated by the national assembly. His position was one of singular difficulty. Apart from the rivalry of the factions within the assembly, there was the question of the Muslim minority, reduced to 40,000 but still a force to be reckoned with. Zaïmis showed great skill and studied impartiality, and his administration was a marked success. Order was restored, and, Zaïmis having called the attention of the powers to the fact that the conditions they had laid down as preliminary to evacuation—(1) the organization of a local *gendarmérie*; (2) the maintenance of the tranquillity of the island; (3) the complete security of the Muslim population—had now been fulfilled, the powers informed him on May 11, 1908, of their intention to begin the evacuation at once and complete it within a year. The first withdrawal of the troops (July 27), hailed joyfully by the Cretan Christians, led to rioting by the Muslims, who believed themselves abandoned to their fate.

Meanwhile Zaïmis had made a further advance toward the annexation of the island to Greece by a visit to Athens, where he arranged for a loan with the Greek National bank and engaged Greek officers for the new *gendarmérie*. The issue was precipitated by news of the revolution in Turkey. On Oct. 12 the Cretan assembly once more voted the union with Greece, and, in the absence of Zaïmis, elected a committee of five to govern the island in the name of the king of Greece.

On July 26, 1909, the powers withdrew their remaining troops. The Cretans hoisted a Greek flag; the Turkish government adopted a minatory tone to Greece, and the powers cut down the offending flagstaff; war was postponed, but the humiliation was not forgotten. On Oct. 14, 1912, the eve of the First Balkan War, Venizelos, then Greek premier, admitted the Cretan deputies to the Greek chamber; Stefanos Dragoumis was sent to Crete as general administrator. Article 4 of the treaty of London (1913) ceded Crete to Greece. After that time its history was merged in that of Greece (*q.v.*).

The island still from time to time, however, played a separate part on the international stage. It was on Crete that in March 1935 Venizelos, then in voluntary exile from Athens, put himself at the head of the abortive revolution which sought in vain to frustrate the restoration of the Greek monarchy. It was to Crete that the Greek king George II and his government retired, with their British allies, after German forces had overrun mainland Greece in April 1941. With a view to establishing a legitimate government on Greek soil, the king then appointed a Cretan, Emmanuel Tsouderos, as prime minister as well as a Cretan minister of war; but barely a month later German air-borne troops captured Crete, and the king and government with most of the British forces retreated from Crete to Egypt. (See *WORLD WAR II: The Balkan Campaigns*.) Resistance to German occupation on the island never entirely lapsed between 1941 and 1945. But the resistance movement never reached the same scale or violence as on the mainland, partly because the Greek communists found less fertile soil in Crete for their revolutionary activities, and partly because a high proportion of Cretans of military age, who had formed the Cretan division in the mainland army, were unable to return to

the island during the remaining years of the war. Liberation came to Crete only with the final surrender of Germany in May 1945, though most of the countryside had already long passed out of German control.

#### IV. POPULATION AND ADMINISTRATION

At the Turkish conquest (see *History* above) part of the popula-

*Departments (Nomoi) with Their Capitals*

<i>Nomoi</i>	Area (sq. mi.)	Pop. (1961)	Capital	Pop. (1961)
Iraklion (Lasithi) . . .	1,020	208,374	Iraklion (Candia)	61,458
Lasithion (Lasithi) . . .	702	73,880	Ayios Nikolaos	3,709
Rethymnon (Rethimni) . . .	578	69,943	Rethymnon (Rethimnon)	14,909
Canea (Khania) . . .	917	131,061	Canea (Khania)	38,467

tion was converted to Islam, though the Cretan Muslims retained their Greek surnames and speech. During the Greek War of Independence (1821–28) Crete, which had risen together with the Greeks of the other islands and mainland, was occupied by Egyptian troops sent at the request of the sultan by his vassal Mohammed Ali. The population, which under Venetian rule was estimated at about 260,000, became greatly depleted during the years of war and was estimated in 1836 at about 130,000. In the following years it increased again and, according to a census taken by the Turkish authorities in 1881, reached the figure of 279,165, of whom 205,010 were Orthodox Greek Christians, 73,234 Muslims and 921 of other denominations. The Muslim element predominated in the principal towns, of which the population was: Candia (Iraklion; *q.v.*) 21,368, Khania (Canea; *q.v.*) 13,812, Rethimnon 9,274. In June 1900, after Crete had become autonomous, a fresh census registered the population at 301,273, the Christians having increased to 267,266 while the Muslims through wholesale emigration had fallen to 33,281. In 1923, after the Greco-Turkish War of 1919–22, the remaining Muslim population emigrated under the Lausanne convention for the exchange of populations between Greece and Turkey, which made emigration compulsory for all except the Orthodox Christian inhabitants of Constantinople and the Muslim inhabitants of Western Thrace. The place of the Cretan Muslims was taken by Greek refugees from Asia Minor, also exchanged under the convention.

At the census of 1928, the population of Crete was returned at 386,427. In the 1961 census the island had a population of 483,075.

Cretans are said to be hospitable, frank and full of vitality, although given to violence. The vendetta survives in many parts of the island. In ancient times the people had a bad reputation as is shown by the poet's appraisal: "The Cretans are always liars, evil beasts, slow bellies," which St. Paul quoted to St. Titus (first bishop of Crete). Between King Minos and Premier Venizelos there have been few celebrated names in its history, but that of El Greco (Domenico Theotocopuli, 1541–1614), the great painter, should not be forgotten; and the author of the long epic poem *Erotokritos* (probably Vincenzo Kornaros or Cornaro, in the 17th century) deserves also to be recorded.

After the incorporation of Crete in the Greek kingdom, the island became a Greek province administered by a governor general. The old departmental divisions were retained. There are today four departments (*Nomoi*), Canea, Iraklion, Rethymnon and Lasithion, each governed by a prefect (*Nomarch*). The provinces are subdivided into 546 municipalities and communes for local government purposes, each with a mayor and municipal or communal council elected by universal suffrage. These councils, as in continental Greece, enjoy limited powers of taxation. In 1953 the post of governor general was suppressed, the administration remaining exclusively in the hands of the prefects who came directly under the minister of the interior in Athens. Crete sends 18 deputies to the Greek parliament.

(A. A. Pa.)

#### V. THE ECONOMY

1. *Agriculture*.—Agriculture is the mainstay of the economy of Crete and provides five times as much employment as industry, mining and transport combined.

Such is the rocky and barren nature of much of the island that only about 13% of its surface (not counting those parts given over to orchards and olive groves) is cultivated—an even lower proportion than in mainland Greece—and many of the fields are only small stoney terraces, laboriously reclaimed from the hill-sides. Cereals form the staple of the Cretan diet and about half of the cultivated land is devoted to them. By contrast with mainland Greece, Crete grows more barley and oats than wheat, a difference which is explained by the inferior quality of the soils on the island. The fertile plain of Mesara, one of the great granaries of the Roman empire, produces much of the island's wheat; but in addition considerable quantities have to be imported.

Most of the arable land is worked in small holdings by independent proprietors who live in nearby villages. At progressively higher levels up the hill slopes are raised fruits, vines, olives, cereals and animals, and together these provide most of the necessities of life. Sheep and goats produce an important part of the standard diet, as well as wool and hair. The shepherds are semi-nomadic and each summer drive their flocks to the high mountain pastures. This system of farming is essentially for local subsistence and in it the cultivation of the cash crops of tobacco and cotton, which are important on the Greek mainland, plays virtually no part. There is, however, some commercial cultivation of olives, of grapes and of oranges. The olive, which is the only possible crop over many hilly tracts, is of great importance, and Crete accounts for more than a third of the total olive production of Greece. Cretan wines and grapes are famous for their high quality and Crete alone in Greece produces raisins. There is a regular export of these commodities, as well as of olive oil, for the most part to the Greek mainland. The oranges (e.g., mandarins) of Crete, also of high quality, come mainly from the district of Canea. The only other important agricultural export is the carob, of which Crete produces about nine-tenths of the Greek crop, mainly for sending to France.

**2. Mining and Industry.**—Although in past times Crete produced a range of minerals, its present output, except for limestone, gypsum and other quarry stones, is negligible. The deposits of copper, lignite, iron, chrome, lead and zinc are now small, of poor quality and remote.

The industries of Crete are on a small scale and mainly concerned with the processing of foodstuffs; for example, milling, olive crushing and the drying of grapes. Soap from the olive residue is made at Iraklion, Canea and Rethymnon, and some is exported. Iraklion and Canea have some small tanneries, textile mills and steel foundries for making farming tools. Cottage industries, notably weaving, embroidery and wood carving, are common, but not organized.

**3. Communications.**—Crete has no railways, except for some short industrial lines. There is one main metalled road, of indifferent quality, the length of the north coast and four branch roads, often impassable in winter, to the south coast at Palaiochora, Khora Sfakion, Timbaktion and Serapetra. See also references under "Crete" in the Index. (Wm. C. B.)

**CRETINISM** is a condition resulting from the failure of the thyroid gland to secrete its hormone from the time of intrauterine life or very early infancy. The absence of thyroid hormone during this critical period leads to a characteristic failure of growth and development and a serious mental deficiency.

Cretinism can seldom be diagnosed before the age of three months. Its earliest manifestations—sluggishness, a heavy expression and piglike appearance of the eyes and a yellowish tint of the cheeks—are difficult to detect. As time passes, however, the full-blown syndrome, including many of the characteristic signs of adult myxedema (hypothyroidism), becomes clearly recognizable. The face is so typical that all cretins closely resemble each other. It is round and yellowish with a wide, flat, thick nose, thick lips and enlarged, often protruding tongue with associated drooling. The voice sounds deep and harsh. The skin is dry and thickened with sparse, dry, brittle hair. Growth is markedly retarded, the resulting dwarfism being characterized by disproportionately short extremities. The belly protrudes and umbilical hernias are not unusual. Dentition is retarded. Sexual maturation is held in abeyance. Hearing is impaired. Walking and talking are not undertaken at the usual age and mental growth is very slow. Imbecility is the rule in the untreated adult cretin. The general health of the untreated cretin is poor, and death has often occurred during early adult life from intercurrent ailments.

In areas in which endemic goitres prevail, endemic cretinism is also observed. It is the general opinion that these endemics are due to the lack of sufficient iodine in the drinking water and food. Iodine is an integral part of the thyroid hormone. When faced with chronic iodine deprivation and a resulting difficulty in synthesizing hormone in sufficient quantity, the gland enlarges; a goitre develops, and in some cases hypothyroidism ensues. Endemic cretinism only occurs when the parents have endemic goitres. The thyroid gland in endemic cretinism is incapable of secreting hormone; a goitre is usually present, but atrophic glands have also been observed. Sporadic cretinism occurs in non-goitrous regions in the children of normal parents. It is thus an unexpected but relatively rare disorder. The thyroid gland is usually atrophic or absent. The cause or causes are unknown.

The diagnosis of cretinism when it is fully developed is not particularly difficult. The problem of differentiating it from Mongolian idiocy has been frequently emphasized; although there may be some superficial similarities, any confusion in diagnosis should be resolved in relatively short order. The Mongolian idiot does not exhibit sluggishness, retarded growth and sexual development nor the classical signs of myxedema, such as thickened dry skin. Furthermore the basic defects of the Mongolian idiot are not corrected by treatment with thyroid extract.

It is imperative that the diagnosis of cretinism be made very early. The longer the organism as a whole is deprived of thyroid hormone the more irreversible become the defects of cretinism. If treatment is begun at three to six months of age, the child will probably develop in a normal fashion with no detectable residual. However, the longer the deficiency is untreated after this age the greater the likelihood of incomplete recovery. This is particularly true with respect to the nervous system. When treatment is not begun until late childhood some general improvement may be noted, but the imbecility persists. In some cretins the late introduction of therapy produces an unmanageable state of hyperirritability, and the patient is best managed by discontinuing this specific treatment. Treatment is with desiccated thyroid extract administered orally. The daily dosage varies with the age and size of the child, but in general the maximum nontoxic dose is given. It must be continued for the remainder of the patient's life. If it

is discontinued hypothyroidism develops. See also ENDOCRINOLOGY; HORMONES; MYXEDEMA.

See S. C. Werner (ed.), *Thyroid; a Fundamental and Clinical Text* (1955). (R. L. L.)

**CRETONNE**, the name of a class of printed cotton fabrics used chiefly for furniture upholstery, hangings, window drapery, and other household purposes. The finer and lighter textures of cretonnes are also made into smocks and other garments for women and children. The name is said to be derived from Creton, a village in Normandy where linen was made.

**CREUSE**, a *département* of central France, comprising most of the ancient province of Marche (q.v.). Pop. (1962) 163,515. Area 2,146 sq.mi. Bounded north by Indre and Cher, east by Allier and Puy-de-Dôme, south by Corrèze and west by Haute-Vienne, it is situated in the northwestern part of the Massif Central and is comprised mostly of granite and other ancient crystalline rocks which form plateau country, inclined northward from the highest tracts in the south where the altitude exceeds 3,000 ft. Most of the *département* lies in the upper basin of the Creuse river, but portions of the westward drainage to the upper Vienne and the northeastward drainage to the upper Cher are included. The poor, acid and often badly drained soil and a chilly, wet climate limit farming. The arable area, as well as the moorland, has been reduced in favour of improved grasslands, and on the remaining arable land in the valleys poor grain crops have tended to be replaced by fodder crops. Farming has become increasingly pastoral and concerned with the rearing of livestock, especially cattle. There are a small coal field at Ahun and some scattered, unimportant ore workings. Some old established textile and leather industries survive; Aubusson is noted for its carpets, and Bourgneuf its porcelain industry. But the *département* is a rural backwater, off main railways and roads, and Guéret and Aubusson (qq.v.), the centres of the two *arrondissements* that constitute the *département*, are the only towns with more than 5,000 inhabitants. Guéret is the capital of the *département* which, with Haute-Vienne, forms the diocese of Limoges. The court of appeal is also at Limoges. Creuse forms part of the educational division (*académie*) of Clermont. (AR. E. S.)

**CREUSOT, LE:** see LE CREUSOT.

**CREUTZ, GUSTAV PHILIP**, COUNT (1731-1785), Swedish poet, whose mastery of formal elegance reflected a sophisticated Epicureanism and greatly influenced Swedish poetic style, was born in May 1731, at Anjala, a family estate in Finland. In 1751 he went to Stockholm. Creutz and a young friend of his with literary ambitions, Count Gyllenborg, became closely associated with an already well-known poet, Hedvig Charlotta Nordenflycht; some of their works were published together. From 1756 Creutz held a post at court, and he was sent to Madrid as ambassador in 1763, and to Paris in 1766. Gustavus III recalled him in 1783 and heaped honours upon him. Creutz died at Stockholm on Oct. 30, 1785.

Creutz's literary output is slight; in 1763 he practically closed his career as a poet. His unusually musical diction and his striving for correctness in metre and style made him outstanding as an innovator in Swedish poetic diction. His masterpiece is *Atis och Camilla* (published 1762), a pastoral epic, for long the most admired poem in the Swedish language.

**BIBLIOGRAPHY.**—Creutz's collected poems were published in *Vitterhetsarbeten af Creutz och Gyllenborg* (1795). See also G. Castrén, *Gustav Philip Creutz* (1917); O. Levertin, "Vår förmästa herredikt," in *Svenska gestalter* (1903); L. Breitholtz, "Frihetstidens episka diktning" in *Studier i frihetstidens litteratur* (1956). (L. G. Bz.)

**CREUZER, GEORG FRIEDRICH** (1771-1858), German philologist and archaeologist, noted for his theory that the mythology of Homer and Hesiod came from an Eastern source through the Pelasgians (q.v.) and contained elements of the symbolism of an ancient revelation. He was born at Marburg on March 10, 1771, the son of a bookbinder. He studied at Marburg and at Jena, and lived for a time in Leipzig as a private tutor. In 1804 he was appointed professor of philology and ancient history at the University of Heidelberg—a position he held for 45 years with the exception of a short period spent at the University of Leiden.

He was one of the principal founders of the Philological Seminary established at Heidelberg in 1807. The Academy of Inscriptions of Paris appointed him one of its members, and he was made a privy councillor by the grand duke of Baden. He died at Heidelberg on Feb. 16, 1858.

Creuzer's first and most famous work was his *Symbolik und Mythologie der alten Völker, besonders der Griechen* (1810-12), in which he presented his theory of Homeric mythology. The theory became the subject of controversy, and was vigorously attacked by, among others, J. H. Voss and C. A. Lobeck. Creuzer's other works included an edition of Plotinus, a partial edition of Cicero, *Epochen der griechischen Literaturgeschichte* (1802), *Die historische Kunst der Griechen* (1803), *Abriss der römischen Antiquitäten* (1824), *Zur Geschichte altrömischer Cultur am Oberrhein und Neckar* (1833), *Zur Gemmenkunde* (1834), *Das Mithreum von Neuenheim* (1838), *Zur Galerie der alten Dramatiker* (1839), and *Zur Geschichte der classischen Philologie* (1854).

**CREVASSE**, a fissure in a glacier, may be transverse or longitudinal, brought about by tension due to unequal rates of movement, the central part generally moving faster than the margins, and (or) movement over an uneven surface. Irregular pinacles of ice between crevasses of great magnitude on steep slopes are known as *séracs* (see GLACIER). The word crevasse is also applied to wide cracks in the raised banks of rivers and canals.

**CRÉVECOEUR, MICHEL GUILLAUME JEAN DE** (1735-1813), French-American author known as ST. JOHN DE CRÉVECOEUR and, especially in America, as J. HECTOR ST. JOHN and the "American Farmer." Born Jan. 31, 1735, at Caen, Normandy, after studying in Jesuit schools and spending four years as an officer and map maker with Montcalm in Canada he chose in 1759 to remain in the new world. He wandered in the Ohio and Great Lakes region, took out citizenship papers in New York in 1765, became a farmer in Orange county, and married Mehitable Tippet in 1769, by whom he had three children.

When the American Revolution broke out Crèvecoeur, the peaceful, contented farmer, found himself in an untenable position because his wife was from a Loyalist family and he had friends and neighbours among the opposite faction. Persecuted by both sides, he left rebel country only to languish for months in an English army prison in New York city before sailing for Europe in 1780, accompanied by one son. In London, using his American name of J. Hector St. John he arranged for the publication in 1782 of twelve essays called *Letters From an American Farmer*.

Within two years this book, charmingly written, optimistic and timely, went through eight editions in five countries and immediately made its author famous, gaining him influential patrons such as Buffon, Franklin and Mme. D'Houdetot, a membership in the Academy of Sciences, and an appointment as consul to three of the new states in America. Before assuming his duties in 1784, Crèvecoeur translated and added to the original twelve essays, and in that year his two-volume *Lettres d'un Cultivateur Américain* was published in Paris.

In America again, Crèvecoeur found his home burned, his wife dead and his daughter and second son with strangers in Boston. Reunited with his children, he set about organizing a packet service between the United States and France, continued an interest in botany and published articles on agriculture and medicine. A two-year furlough in Europe resulted in a larger, second edition of the *French Letters*, in three volumes in 1787. Recalled from his consulship in 1790, Crèvecoeur wrote one other book on America, published in 1801 in three volumes as *Le Voyage dans la Haute Pensylvanie et dans l'État de New York*. He lived quietly in France and Germany until his death in 1813.

Because of his letters, Crèvecoeur was not only for a while the most widely read commentator on America, but also a great favourite with romanticists like Lamb and Campbell and with revolutionists like Brissot. His stature was further increased in the 1920s when a bundle of his unpublished English essays was discovered in an attic in France. These were brought out in 1925 as *Sketches of Eighteenth Century America, or More Letters From an American Farmer*. Crèvecoeur's books outline the steps through which

new immigrants passed, analyze the religious problems of the new world, describe the life of the whalers of Nantucket, reveal much about the Indians and the horrors of the Revolution, and present the colonial farmer—his psychology and his daily existence—more completely than any contemporaneous writings were able to do it. The passage containing his "melting pot" theory and answering the question "What is an American?" is widely quoted, and historians of the frontier depend heavily on his documented account of the stages by which the log cabin became the opulent farmhouse. For the lover of literature Crèvecoeur provides natural history essays like those of Thoreau, descriptions of nature, Indian legends, poignant tales of the Revolution and melancholy, sentimental stories of slavery and the disappearance of the red men. His charming style, keen eye and simple philosophy are universally admired.

**BIBLIOGRAPHY.**—The best books on Crèvecoeur are in French, Robert de Crèvecoeur, *Saint John de Crèvecoeur, Sa Vie et Ses Ouvrages* (1883); Howard C. Rice, *Le Cultivateur Américain* (1933), which has an excellent bibliography; in English, Julia Post Mitchell, *St. Jean de Crèvecoeur* (1916). The *Letters From an American Farmer* is available in the Everyman edition but with an introduction that is much out of date. (P. G. A.)

**CREW, NATHANIEL CREW, 3RD BARON** (1633–1721), English clergyman and favourite of James II, was born on Jan. 31, 1633, the fifth son of John Crew of Northamptonshire, who had been created Baron Crew of Stene in 1661 in recognition of his services in support of the Restoration. Nathaniel Crew was educated at Lincoln College, Oxford, was ordained in 1664, and was elected rector of Lincoln College in 1668. Having won the favour of James, then duke of York, by conniving at the duke's leanings toward the Roman Catholic Church, Crew received rapid preferment, becoming dean and precentor of Chichester in 1669, clerk of the closet to Charles II shortly afterward, bishop of Oxford in 1671, and bishop of Durham in 1674. In 1676 he became a member of the privy council. After the accession of James II, Crew received the deanery of the Chapel Royal.

In 1686 Crew served on the revived ecclesiastical commission which suspended Henry Compton, the bishop of London, and he subsequently shared the administration of the see of London with Thomas Sprat, the bishop of Rochester. In 1687 he was a member of another ecclesiastical commission, which suspended the vice-chancellor of the University of Cambridge for refusing to grant the degree of M.A. to a monk who would not take the customary oath. As James's power began to decline, Crew dissociated himself from the court, however, and he attempted to ingratiate himself with the new government by voting for the motion that James had abdicated. Despite this effort, he was excepted from the general pardon of 1690, but no action was taken against him. He retired to his see, which he was permitted to retain and of which he proved to be an able administrator. In 1697 he succeeded his brother Thomas as 3rd Baron Crew, and upon his death on Sept. 18, 1721, the barony became extinct. He left the large estates which he had purchased in Northumberland to be used for charitable purposes, including benefactions to Lincoln College and to Oxford University.

**CREW, ROBERT OFFLEY ASHBURTON CREWE-MILNES, 1ST MARQUESS OF** (1858–1945), British statesman, chiefly remembered for his part in securing the passage of the Parliament act of 1911, was born in London on Jan. 12, 1858, the only son of the 1st Baron Houghton (*q.v.*), and was educated at Harrow and at Trinity college, Cambridge. He was brought up in the best Liberal traditions, in the society of the most interesting people of the time. He soon developed a wide interest in European literatures, and like his father wrote occasional verses (publishing *Stray Verses* in 1891), which he regarded with a modesty never shown by his more flamboyant parent. Milnes was also unlike his father in his love for the English countryside and its traditional pursuits, especially the turf. While he was comparatively young, he had to face a series of domestic tragedies: the deaths of both his parents, of his young wife in 1887 and of his only son in 1890.

Milnes became assistant private secretary to the foreign secretary, Lord Granville, in 1884. He entered the house of lords on his father's death in 1885. After a brief period as junior whip

in the house of lords, he was appointed lord lieutenant of Ireland by Gladstone in 1892. The appointment was criticized on the grounds of his youth, but in Ireland he displayed his great qualities of wisdom, tact and detachment. He left Ireland with few regrets after the Liberal defeat in 1895, and was given an earldom, choosing the title Crewe because his uncle Lord Crewe had recently died bequeathing him large family estates.

In 1899 Crewe married Lady Margaret Primrose, daughter of the former prime minister the earl of Rosebery. He held various major offices after the Liberal victory of 1905, notably that of colonial secretary, 1908–10, and secretary for India, 1910–15, when he implemented the Morley-Minto Indian reforms and attended George V to the Delhi durbar (1911). He was also leader of the house of lords from 1908. At one moment he became ill from overwork. H. H. Asquith called him "the most underrated man in England." He played a major part in the constitutional crisis of 1909–11, directing Liberal strategy in the lords, and handling relations with the crown; together with Asquith he was the butt of the most virulent Tory abuse. Crewe, who had been made a marquess in 1911, remained in the cabinet until 1916, when he resigned with Asquith. He held office once more, in Ramsay MacDonald's short coalition of 1931.

In 1922 Crewe wanted to retire, because of the tragic death of his only son by his second marriage, but the foreign secretary Lord Curzon persuaded him to become ambassador in Paris, and as such he strengthened the entente at a period of acute strain in Anglo-French relations. On his return to London in 1928, Crewe gradually withdrew from public life, although he was still Liberal leader in the house of lords. He occupied his leisure in literary pursuits, and wrote his *Life of Rosebery* (1931). He died at his home in Surrey on June 20, 1945.

Crewe inspired general respect by his keen intelligence, wide culture and singular absence of prejudice. In his lifetime he was often called "the last of the great English gentlemen," but more than this he was a striking example of a great landowner whose political motives were invariably disinterested, and who calmly and consistently upheld political convictions regarded as dangerously radical by his own class.

See James Pope-Hennessy, *Lord Crewe* (1955). (J. P.-H.)

**CREWE**, a municipal borough (incorporated 1877) of Cheshire, Eng., is 24 mi. E.S.E. of Chester. Pop. (1961) 53,195. The town, built on the old Oak farm estate in the parish of Monks Coppenhall, took its name from Crewe hall, seat of Lord Crewe. Now one of the main railway junctions of England, it was created in the 19th century by its situation on a nodal point for lines from London, Manchester, north Wales and Holyhead, north Staffordshire and Hereford. The site was selected by the former London and North-Western railway for its workshops and marshaling yard. The modern town, still mainly dependent on the railway industry, is inhabited chiefly by railway employees.

**CRIBBAGE**, a game of cards in which the object is to form counting combinations that usually are scored by moving pegs on a special cribbage board, the dealer scoring an extra hand, the crib, formed of discards. According to English antiquary John Aubrey (*Brief Lives*), cribbage was invented by Sir John Suckling (1609–42). It was probably an improvement of an older game, noddly, in which the game was 15 or 21 up, marked with counters or by means of a special scoring board. At cribbage, a knave in the crib was formerly called "knave noddly," now corrupted to "his nobs." Cribbage is essentially a game for two players, although it can be played by three or four. The full pack of 52 cards is used. The right to deal alternates; the loser of each game is usually first dealer in the next. Formerly each of the two players was dealt five cards, but in modern play the number is six. Nondealer cuts the balance of the pack, and dealer turns up the top card of the lower packet. This card, left face up, is the starter. If it is a knave, dealer pegs (scores) 2, called "2 for his heels."

Scoring is called pegging because it is done by moving pegs on a special scoring device, the cribbage board. This consists essentially of a tablet with 60 holes for each player, in two rows of 30. Two pegs are furnished to each player, and each increment to the score is marked by jumping the rearmost peg ahead of the

Suitable intervals are allowed for lunch and tea and between innings. Minor teams often play half-day games (say, 2:30 P.M.—7:00 P.M.).

#### How the Game Is Played.—

The nonbatting side take up positions in the field (*see drawing*). One of their number bowls the ball from one wicket to the other. The first batsman (the striker) guards his wicket by standing with one foot behind the popping crease. His partner stands at the bowler's end within his ground; i.e., behind the popping crease. The object of the bowler is to hit the batsman's wicket, or dismiss him in other ways (*see list of Methods of Dismissal*).

The object of the batsman is to hit the ball sufficiently hard for him to score a *run*; i.e., to enable him to reach the other end of the pitch before any fieldsman can pick up the ball and throw it to the stumps. As soon as he runs, his partner (the nonstriker) runs toward him, and once they have crossed and each has made good his ground at the opposite end, one run is recorded to the striker; if there is time they will run back for a second run, crossing again: up to six runs can be scored from any one stroke. If an even number is scored, the striker will receive the next ball, but, if an odd number, then the nonstriker will be at the wicket opposite the bowler and will face the next ball. Only runs scored from the bat count to the batsman, but to the side's score may be added the following extras:

(1) *byes* (when a ball from the bowler passes the wicket without being touched by the bat and the batsmen are able to make good a run); (2) *leg byes* (when in similar circumstances the ball has touched any part of the batsman's body except his hand); (3) *wides* (when a ball passes out of reach of the striker); (4) *no-balls* (for a fair delivery the ball must be bowled, not thrown or jerked, and in the delivery stride, the bowler's front foot must not land "clear beyond the popping crease," and his back foot must land "within and not touching the return crease or its forward extension"; a breach of these conditions constitutes a no-ball, off which a batsman cannot be cut—except under *Methods of Dismissal* [5], [7], [8] and [9] [*see list*])—and which he may therefore try to smite, apprised in time by the umpire's cry of "no-ball"). When a ball, from a hit or any of the extras just mentioned, reaches the boundary, running ceases and four runs are added to the score. If the batsman hits the ball full-pitch over the boundary he scores six runs.

The ball is bowled from each wicket alternately in *overs* of six balls (eight in Australia and South Africa), not counting wides and no-balls. When the requisite number have been bowled, a new over is begun by a different bowler at the opposite end to the batsman at the former bowler's end, with a corresponding adjustment of the field. Subject to this alternation of overs, any mem-

CRICKET FIELD SHOWING PRINCIPAL PLAYING POSITIONS

ber of the fielding side may bowl at either end as many overs as his captain decides, but the same bowler may not bowl two consecutive overs. If a bowler delivers a complete over without a run being scored from the bat, he has achieved a *maiden over*, a feat of some accuracy.

The ordinary ways in which a batsman or striker can be dismissed (put out) are indicated in the accompanying list. When a batsman is out bowled, leg before wicket or hit wicket the credit is taken by the bowler, who is said to have "taken the batsman's wicket." Among the methods of dismissal hitting the wicket, handling the ball, hitting the ball twice and obstructing the field are of rare occurrence.

#### Methods of Dismissal

1. *Bowled*.—The batsman is out *bowled* if the bowler breaks the wicket; i.e., dislodges a bail with the ball.
2. *Caught*.—He is out *caught* if a ball hit by the batsman is caught before it touches the ground.

3. *Stumped*.—He is out *stumped* if, in playing a stroke, he is outside the popping crease (out of his ground) and the wicket is broken by the wicketkeeper with ball in hand.

4. *Leg before wicket (l.b.w.)*.—Essentially, illegal interference, whether accidental or intentional, with a ball that otherwise, in the opinion of the umpire, would hit the wicket: the batsman is out l.b.w. if he intercepts with any part of his person, except his hand, which is in line between wicket and wicket, a ball which has not first touched his bat or his hand and which has or would have pitched (hit the ground) in a straight line between the wickets or on the off side, provided the ball would have hit the wicket.

5. *Run out*.—Either batsman is out *run out* if, while the ball is in play, his wicket is broken while he is out of his ground. If the batsmen have passed each other, the one running for the wicket that is broken is out; if they have not crossed, the one running from that wicket is out.

6. *Hit wicket*.—The batsman is out *hit wicket* if he breaks his own wicket with his bat or any part of his person while playing at the ball.

7. *Handling the ball*.—Either batsman is out if he touches the ball with his hands while it is in play.

8. *Hitting the ball twice*.—Batsman is out if he hits the ball, except in defense of his wicket, after it has been struck or stopped by any part of his person.

9. *Obstructing the Field*.—Either batsman is out if he willfully obstructs the opposite side.

The disposition of the field will vary widely according to the technique of the bowler or of the batsman, the condition of the pitch, the state of the game, and the tactics determined by the captain. He may place his fieldsmen as he thinks best, and he may alter their positions, if he wishes, after each ball. There are no foul lines in cricket as there are in baseball so any hit is a fair ball.

The objects of the captain of the fielding side are: (1) to place his men in positions where the batsman may give a catch (in baseball terminology, hit a line drive or a fly ball to a fielder); and (2) to save runs; i.e., to block the path of the ball from the batsman's scoring strokes (intercept or trap grounders). The tactical possibilities for a thoughtful and ingenious captain in directing the battle of wits between his bowlers and fieldsmen and the batsmen are manifold and constitute one of the charms of the game for player and spectator alike.

The names of the generally accepted positions are shown in the drawing. As there are only 11 players in a team, two of whom must be the bowler and wicketkeeper, only nine other positions can be occupied at any one time. The field is spoken of as being divided lengthwise into "off" and "leg," or "on," sides in relation to the batsman's stance depending upon whether he bats right- or left-handed; the "off" side is the side facing the batsman and the "leg" or "on" side is the side behind him as he stands to receive the ball.

To sum up: the object of the bowler is primarily to get the batsman out, and only secondarily to prevent him from getting runs. The object of the batsman is to make runs, for only runs can win a match, but to make runs he must "stay in." The object of each fielder (and of the general distribution of the field) is first, to dismiss the batsman, and secondly, to prevent his making runs. The arts of batting, bowling, and fielding are therefore a fusion of attack and defense, but ideally attack will always dominate.

*Bowling* can be right- or left-arm. For a fair delivery the ball must be propelled, usually overhand, without bending the elbow. The bowler may run any desired number of paces as a part of his delivery, as in bowling (with the restriction, of course, that he does not cross the bowling crease), but the ball is not rolled on the ground although it generally hits the ground (the pitch) before reaching the batsman. The first requisite of a good bowler is command of length; i.e., the ability to pitch (bounce) the ball on a desired spot, usually at or slightly in front of the batsman's feet and varying with the pace of the bowler, the state of the pitch and the reach and technique of the batsman. The second requisite is command of direction. On this foundation a bowler may elaborate with variations of fingerspin, swerve, alteration of pace and flight, the path of the ball and the manner in which it is propelled that lend deceptiveness and uncertainty as to exactly where and how it will pitch. A *good-length ball* is one which causes the batsman to doubt whether to come forward to play his stroke or to move back. A *half volley* is a ball pitched so far up to the batsman that

SPORT AND GENERAL PRESS AGENCY, LTD.

F. S. TRUEMAN BOWLING FOR ENGLAND IN A TEST MATCH AGAINST AUSTRALIA: A. K. DAVIDSON (AUSTRALIA) AND UMPIRE J. LANGRIDGE WATCH THE DELIVERY

he can drive it fractionally after it has hit the ground without having to move forward. A *yorker* is a ball pitched on or inside the popping crease. A *full pitch* is a ball which the batsman can reach before it hits the ground. A *long hop* is a ball short of good length or "short of a length."

The primary purpose of the spin in bowling is to bring the ball up from the pitch at an angle or in a direction that is difficult for the batsman to anticipate. The varieties of spin are: *off-break*, the ball on pitching, that is, hitting the ground, turns from the off side of the wicket; *leg break*, the reverse of off-break; *top-spin*, the ball, on pitching, gathers pace but does not turn; *googly*, a ball bowled by a right-arm bowler which deceives the batsman by turning from the off, though apparently bowled with a leg-break action; *chinaman*, an off-break ball bowled by a left-arm bowler. Occasionally, left-arm bowlers bowl a googly which, on pitching, turns from the leg.

The two swerves are the *inswinger*, which moves in the air from off to leg, and the *away- or outswinger*, which swerves from leg to off.

*Batting*.—A batsman may play right-handed or left-handed. Good batting is based on a straight (i.e., vertical) bat with the full face presented to the ball.

The chief strokes are: *forward stroke*, in which the batsman advances his front leg to the pitch (direction) of the ball and plays it in front of the wicket (if played with aggressive intent, this stroke becomes the *drive*); *back stroke*, in which the batsman

SPORT AND GENERAL PRESS AGENCY, LTD.

SIR DONALD BRADMAN (AUSTRALIA) AT THE FINISH OF A CUT: S. C. GRIFFITH (ENGLAND) IS WICKETKEEPER AND W. J. EDRIK IS AT SLIP

moves his rear leg back before playing the ball; *leg glance* (or *glide*) in which the ball, when pitched in a line with or outside the batsman's body, is deflected behind the wicket on the leg side; *cut*, in which the batsman hits a ball on the uprise (after hitting the ground on the off side) over and down behind the wicket or through the slips with a vigorous whiplike action of the wrists.

**Fielding.**—The ideal fieldsman is a fast runner, with keen eyesight, quick reactions and ability to throw straight and far. He should be able to anticipate the batsman's strokes, move to cut off the ball in its path, and pick it up and throw it to the stumps in one movement. He must judge the flight of the ball in the air to make a safe catch. By his alertness and skilful play he can save runs and contribute to a batsman's downfall.

The *wicketkeeper*, or catcher, is a specialist position requiring abnormally quick reactions, sharp eyesight, and courage. He is the hardest-worked member of the team, and must concentrate on every ball, whether standing 12 to 15 yd. behind the stumps for the fast bowlers, or crouching close to them for those of slow or medium pace.

### CRICKET IN ENGLAND

**Origin.**—Samuel Johnson derives the name cricket from "cryce," Old English, a stick. The word still survives in Cornwall and Devon in the sense of hedge sticks. The termination "et" is itself a common diminutive, and the game would then take its name from its weapon of attack, a little staff, stick, or bat.

For the practice of cricket as an elementary form of club ball there is pictorial evidence as early as the middle of the 13th century. The first written reference to the game is possibly to be found in an extract from the wardrobe accounts of 1300, in Edward I's reign, which referring to certain sums disbursed on behalf of the young Prince Edward alludes to a game called *creag*. Cricket was being played by boys of the free school of Guildford in or about 1550. Oliver Cromwell is reported as having indulged in his youth in cricket and football, and in 1650 a scholar at Winchester is referred to as "attempting to wield a cricket bat." There appears to have been a cricket club at St. Albans as early as 1666. In 1668 the proprietor of the Ram Inn, Smithfield, London, had been rated for a cricket ground, and in 1707 Chamberlayne's *State of England* included cricket among the people's recreations.

**Early History.**—Cricket has been played under recognized rules at least since the beginning of the 18th century. The first definite match of which there is record was played in Sussex in

1697, 11-a-side and for a stake of 50 guineas. In 1719 the "Londoners" met the "Kentish men" in what was virtually the first county match, London being synonymous with Middlesex.

The greatest enthusiasm and the most expert skill were concentrated in the southern counties near London. There, on the short turf of the open downs, cricket was discovered by Society and transplanted to London and to the home grounds of its noble patrons, for example at the Vine at Sevenoaks, and at Goodwood Park. In London, matches were played on all the southern commons from Chelsea to Clapham. But by far the most famous cricket centre was the Artillery Ground, Finsbury. Here was played on June 18, 1744, the famous match Kent *v.* All England, the first game to be recorded in A. Haygarth's *Scores and Biographies 1744-1878*.

A feature of the play in those days was the heavy stake money and side bets that more often than not depended on big matches. The crowds were often disorderly and violently partisan.

The next stage in the game's development was marked by the rise of the Hambledon Club. On Broad-Halfpenny Down (the historic site later acquired by Winchester College) this little Hampshire village for 30 years challenged and was a match for all comers. Indeed in June 1777, they beat a representative England eleven by an innings and 168 runs. This phenomenal ascendancy resulted in the main from the coincidence in the area of about a dozen men of extraordinary cricket genius who had a profound influence on the evolution of the game's technique. Fortunately, too, was the club in its historian, John Nyren. His *Cricketers of my Time*, together with *The Young Cricketer's Tutor*, edited by Cowden Clarke, both published in 1833, were the first prose classics in cricket's literature.

Hambledon played its last recorded match in 1793, appropriately enough at Lord's, London. This, the acknowledged Mecca of all cricketers, was first opened in Dorset Square as a private ground for certain members of the White Conduit Club by Thomas Lord, a Yorkshireman who was ground superintendent and bowler to the club. In 1809, to avoid a rise in rent, Lord removed to part of the St. John's Wood Estate, and four years later he moved again to the present situation. In each case he relaid the original Dorset Square turf, and he enclosed his newest ground with a high fence and built on it a pavilion and a tavern. The Marylebone Cricket Club (MCC), with its home at Lord's, was founded in 1787 and in its first year it revised the laws, thus proving that from its inception its authority was paramount. It is accepted throughout the world

as the authoritative source of all cricket legislation.

For half a century at least, the MCC was the great match-making agency in cricket, inviting subscriptions from its members to meet match expenses, and advertising in advance at the chief London social clubs. Most of the big matches were still played for money and were a field for heavy wagering by professional backers, games being constantly arranged at odds, whether of numbers or of given men.

In 1836 the first North v. South match was played, clear evidence of the spread of cricket. The missionary efforts of the MCC began in 1846, seconded by the touring cricket of the All-England eleven, which played all over the country and was the focus of attraction wherever it went, winning to knowledge and appreciation of the game whole districts where hitherto it had been unappreciated or undeveloped. Its matches were great trials of budding talent, and many a young professional was discovered and launched on a successful career through its medium. Its success led in 1852 to the secession of some of the leading professionals and their formation into the United All-England eleven. These two teams monopolized the best cricket talent in the country, and the annual match between them at Lord's on Whitmonday, first played in 1862, was for nearly 20 years the great event of the season. Eventually they both gave way before the rising tide of county cricket (see below).

**Technical Developments.**—Cricket was originally a game in which the country lads bowled at a tree stump, or at the hurdle gate into their sheppens. This consisted of two uprights and a crossbar resting on their slotted tops, the latter called a "bail" and the whole gate a "wicket." The fact that the bail could be dislodged when the wicket was struck made this preferable to the stump, which name was later applied to the hurdle uprights.

Early manuscripts differ about the size of the wicket, but by 1706 the pitch was 22 yd. long.

The ball was probably much the same in the 17th century as it is today. Originally it weighed between five and six ounces, and its modern weight and size were laid down in 1774 and 1838, and its circumference was slightly reduced in 1927.

The primitive bat was no doubt a shaped branch of a tree, resembling a modern hockey stick, but considerably longer and very much heavier. The change to a straight bat was made to meet the demand of "length" bowling which had been evolved by the Hambledon cricketers. The bat was shortened in the handle and straightened and broadened in the blade, which led to forward play, driving and cutting. As few bowlers were able to combine length with break, swerve, and flight, batting continued to dominate bowling in

the 18th century. About the same time the first l.b.w. law was promulgated by which the umpire had the impossible task of deciding whether the obstruction had been deliberate. Early in the 19th century most bowlers favoured the high-tossed lob.

The next bowling development was "the round arm revolution" in which many bowlers deliberately threw. Controversy raged furiously, and in 1835 the MCC rephrased the law to allow the hand to be raised as high as the shoulder. The new style led to a great increase in pace. Gradually bowlers raised the hand higher and higher in defiance of the law, until it became more honoured in the breach than in the observance. Matters were brought to a head when all nine professionals of an England eleven playing against Surrey left the field at the Oval in protest against one of their number's being no-balled

for throwing, and as a result, in 1864, the bowler was officially accorded full liberty to bowl overhand. From time to time umpires have had trouble with bowlers who threw, and G. A. R. Lock of Surrey and C. N. McCarthy, the South African fast bowler, when playing for Cambridge University, were no-balled for throwing in 1952. Attempts, including a special meeting of the Imperial (now International) Cricket Conference in 1959, to help umpires by rephrasing the law proved unavailing and in the 1960s fast bowlers G. Griffin (South Africa), I. Meckiff (Australia), and H. Rhodes (England) were all no-balled. C. C. Griffith (West Indies) was often criticized but he was never "called" in a test match.

Most bowling continued to be fast throughout the middle of the 19th century, and though the standard of wicketkeeping was high, the role of long stop, positioning a fieldsman to back up the wicket-keeper, became most important. The batsmen now learned to protect themselves with additional armour. Pads and tubular batting gloves were invented, and the cane handle greatly increased the resilience of the bat. Thus fortified, batsmen developed their strokes. Hitting and pulling to the leg side became fashionable, forcing strokes on the leg side off the overpitched ball were developed, as were the classic principles of elegance and the straight bat. However, only the best professional batsman could cope with great speed because most pitches were bad. Until 1849, when permission was first given to sweep and roll the pitch at the beginning of each innings, it was unlawful to touch it from the beginning to end of a match.

Gradually the grounds improved, because of the advent of the heavy roller and of the perfection of the lawn mower, and in the 1870s fast bowling declined. The batsmen went over to the offensive and the bowlers fell back on accuracy of length. They also developed off theory, keeping the ball some distance wide of the off stump and concentrating the fieldsmen on the off side of the wicket. The batsmen countered by a policy of masterly inactivity, and the pace of some county cricket became so funereal that interest flagged and attendance fell off. From such a fate the game was saved by a transfusion of new and vigorous blood.

Profiting by the coaching of English professionals, Australians developed their cricket, especially their bowling, and when in 1882 they came to England and defeated its full strength, a further evolution in technique had taken place. Their great bowlers combined pace with spin and variety of flight. They bowled much straighter than the English, and were much more adaptable in their field placing. With the wicket taking off-spin, many catches were held in the then unprecedented place of silly mid-on.

A great wicketkeeper, J. McC. Blackham, stood up to the stumps to a fast bowler, even dispensing with a long stop, and by taking the ball cleanly, even on the leg side, set a new standard in wicket-keeping.

The opening years of the 20th century produced such an orgy of run-getting that a reform of the l.b.w. law was debated, and the MCC denounced the over-preparation of pitches. But the heavy scores were due primarily to the arrival of batsmen who triumphed over much formidable and varied bowling by methods both versatile and individual. This was cricket's "Golden Age."

There now appeared in cricketing vocabulary the googly, a word coined in Australia when B. J. T. Bosanquet, on the 1903-04 MCC tour, first exploited his ability to bowl an off-break with a leg-break action. This freak ball was brought to something like perfection in South Africa, where the matting used to form the surface of the pitch intensified its spin.

Contemporarily bowlers discovered a new weapon for the discomfort of the batsmen—the swerve. Fast left-handers exploited inswerve, and right-handers learned to swing the ball either way, especially into a head wind or in a heavy atmosphere. A final development was the ball from the right-hander which swung into the batsman and dipped at the end of its flight. To supplement this inswinger, the field was largely reoriented, with the on side reinforced at the expense of the off.

To meet these new problems batsmen had to adjust their technique. K. S. Ranjitsinhji and C. B. Fry led the way by abandoning the long-striding forward stroke and making back play, together with a mastery of all on-side strikes, the foundation of their batting. But with the less gifted majority of batsmen, a two-shouldered and right-handed defense off the back foot began to predominate, and batting lost its aggression and charm. Such methods played into the hands of bowlers of real pace and of those who could flight as well as spin the ball, but the concentration on defense and the increasingly elaborate preparation of the pitch often thwarted all but the greatest bowlers. The most drastic and dramatic tactic was the so-called "body-line" attack in the 1930s (see *Test Matches* below).

The reaction of authority to the evolution of cricket in the 20th century was visible in a series of attempts to help the bowler and to quicken the tempo of the game. As early as 1902 the bowling crease had been extended in length; in 1907 the use of a new ball after every 200 runs had been legalized; during the MCC tour of Australia in 1924-25 the eight-ball over was first used (this became standard practice in Australia and in South Africa); in 1927 a smaller ball was authorized; in 1931 the size of the wicket was increased; and in 1937 the l.b.w. law was extended to cover balls pitching outside the off stump.

In 1947 the MCC issued a revised code of laws, aimed at the clarification and better arrangement of the previous laws. The extension of the l.b.w. law encouraged the inswinging bowler and the off-spinner, thus further restricting the batsmen's more attractive off-side strokes. The rate of run-getting deteriorated as too many bowlers bowled short of a length and the MCC and other governing bodies were much concerned about slow play. As attendance continued to drop there were widespread appeals for more positive cricket and groundsmen were urged to prepare truer and faster wickets. The MCC's attempts by legislation to instill more enterprising tactics into county cricket failed through inadequate response by players, whose offensive spirit was being dulled by playing six days a week before diminishing crowds. But the introduction of the Gillette Cup One-Day Knockout Competition in England in 1963 was a great success in improving the tempo and bringing back spectators. Players of other countries, with less cricket, were less affected by a defensive complex.

**County Cricket.**—The greater part of first-class cricket, aside from the Oxford v. Cambridge and test matches, is played in the county championship between sides representing counties. The origin of county cricket may be found in local antagonisms of the "home counties." Successive county supremacies were enjoyed by Kent (about 1750); Hampshire (1780-90); Surrey (1790-1810); Sussex (about 1825); and the great Kent eleven of the 1830s and 1840s. Yorkshire first took the field in 1833 (club

formed in 1863) and Nottinghamshire in 1835 (club formed in 1859). Surrey, first organized as a county club in 1845, enjoyed a renewed ascendancy in the late 1850s and early 1860s. Between 1867 and 1870 Yorkshire, with a wholly professional eleven, were champions thrice.

The modern county championship is generally reckoned to date from 1873, when the MCC first laid down rules governing qualification. In the next five years, Gloucestershire, owing almost everything to the Grace brothers, E. M., W. G., and G. F., were champions three times, but it was another ten years before the honour came south again. The 1880s were a great decade for Nottinghamshire, but toward the end Surrey came again and were at the head of the championship table eight times between 1887 and 1895. Yorkshire now enjoyed a great revival. Unlike the great majority of its rivals, its eleven consisted almost entirely of native-born men, and its success was proportionately more popular in the county.

In the last 12 years before World War I the championship was won by six different counties, a variety of fortune that was excellent for the game's welfare. No victory was more popular than that of Warwickshire in 1911, when it became the first county outside the Big Six (Yorkshire, Lancashire, Nottinghamshire, Kent, Surrey, and Middlesex) to win the honour in 34 years. Kent was the most consistent in this period, winning four times, while Surrey carried off the honours in the curtailed 1914 season.

The early years of the 20th century produced in J. B. Hobbs (later Sir Jack) of Surrey and F. E. Woolley of Kent two of the greatest artists the game has known. Hobbs, who was the complete batsman, graced first-class cricket for 30 years during which he amassed records for Surrey and England (61,237 runs, 197 centuries) which by the mid-1960s had not been beaten. Woolley, whose aggregate was second only to that of Hobbs, was cricket's most graceful left-hand batsman.

After World War I, Middlesex had a brief period of triumph, but between 1922 and 1939 the championship was monopolized by the northern counties of which Yorkshire won 11 times, Lancashire 5 and Nottinghamshire and Derbyshire 1 each. The reason for this ascendancy was not difficult to find. Lancashire and Yorkshire fielded largely professional teams which remained virtually unchanged throughout the season. They exhibited a toughness of fibre, an economical competence of technique and a concentration on the game compared with which most of their rivals tended to appear, as in fact some of them continued to be, relatively unskilled. Above all they excelled in the accuracy and hostility of their bowling, supported by aggressive fielding and handled by captains who knew their jobs.

The leading personalities of the Yorkshire team during this era were W. Rhodes, greatest of all slow left-arm bowlers and also a good batsman, P. Holmes and H. Sutcliffe, a famous pair of opening batsmen, who in 1932 made the record partnership of 555 for the first wicket, M. Leyland, a phlegmatic and stout-hearted left-

bander, and the bowlers W. E. Bowes, fast-medium, and H. Verity, slow left-arm. L. Hutton (later Sir Leonard) appeared as the logical successor to Sutcliffe in 1936.

Lancashire won the title five times between 1926 and 1934, thanks primarily to the hostile fast bowling of the Australian E. A. MacDonald, supported by the lively spin and enterprise of C. Parkin and the accurate slow bowling of R. Tyldesley, and to a reputation for solid batting inspired by H. Makepeace, C. Hallows, and F. Watson, supplemented by attractive stroke play by E. Tyldesley.

In 1929 a battery of fast bowlers in H. Larwood, W. Voce, and F. Barratt, coupled with the defensive patience of W. Whysall and the wayward genius of G. Gunn, won the championship for Nottinghamshire. Derbyshire's success in 1936 was the first outside the Big Six since Warwickshire's in 1911.

Had all its talented amateurs been available more regularly, Middlesex might have challenged the northern supremacy. Too much, however, depended on the all-round ability of J. W. Hearne and the batting of E. Hendren, who was one of the world's great batsmen. Quick on his feet, full of strokes, only Hobbs and Woolley scored more runs, and only Hobbs more centuries. G. O. Allen was the greatest of the amateurs. A fast bowler with a beautiful rhythmic action, he was also a correct and skilful batsman.

Despite a wealth of batting headed by Hobbs and A. Sandham, and a number of distinguished captains, such as P. G. H. Fender, D. R. Jardine, and E. R. T. Holmes, Surrey never won the championship between World Wars I and II. Surrey's cricket ground, the Oval, Kennington, London, was a batsman's paradise, and bowlers of the requisite class were not forthcoming.

The feature of Kent cricket was the number of amateur batsmen and brilliant fieldsmen, of whom A. P. F. Chapman was outstanding. But the team was based on three great professionals; Woolley, A. P. Freeman, and L. Ames. Whereas Kent had a number of fine batsmen to support Woolley, its bowling depended virtually on Freeman. Highly accurate, and with pronounced leg-spin to which was added a well-disguised googly, in eight seasons he took 2,090 wickets, with 304 in 1928 as an all-time record. Ames was the finest batsman-wicketkeeper of his generation. He regularly scored more than 2,000 runs a season and kept wicket more than 40 times for England.

Sussex was a particularly attractive team in the 1920s under the captaincy of A. E. R. Gilligan. For a few years Gilligan and M. W. Tate were the best pair of opening bowlers in the country, while Tate was the greatest fast-medium bowler of his time. K. S. Duleepsinhji and the South African A. Melville supplied grace and culture to the batting. Sussex always batted with enterprise and fielded superbly.

Gloucestershire was runner-up in 1929 and 1930, due primarily to the left-arm bowling of C. Parker, who was good on all wickets and the best in England on sticky wickets, and to the majestic batting of W. R. Hammond.

The nucleus of the Yorkshire side which had won the championship in the last three seasons before World War II was sufficiently strong to retain it in 1946, but thereafter it was gradually a waning force before the onslaught of Middlesex and Surrey.

Middlesex had a wonderful season in 1947 under the eager leadership of R. W. V. Robins and inspired by the record-breaking achievements of D. C. S. Compton and W. J. Edrich. Compton, profiting by a hot summer, made the highest aggregate (3,816 runs) and the most number of centuries (18) ever achieved in a season. A genius in his quickness of reaction, speed of foot, versatility, and unorthodox style, Compton ranked with the greatest batsmen of all time. Edrich, too, had a bigger aggregate (3,539 runs) than anyone before him.

Glamorgan, the youngest of the counties, provided the surprise of the century by winning the championship for the first time in 1948. W. Wooller was an enthusiastic captain and invaluable all-rounder, but his side's was a triumph for team spirit and brilliant catching and fielding.

Another of the less fancied counties, Warwickshire, headed the table in 1951, 40 years after its only other success. Amateurs good

enough to be worth their place in first-class cricket and able to spare the time to play regularly were becoming increasingly difficult to find. Warwickshire in 1949 took the bold step of appointing one of its senior professionals, H. E. Dollery, as full-time captain. Two years later he led his team to the top of the table, thus proving that a professional could make a successful captain. Within a few years, five other counties had followed suit.

The 1950s belonged to Surrey. By 1958 it had been champion county for seven consecutive years, and was incomparably the best side in England. The first success coincided with the appointment of W. S. Surridge as captain, and under his enterprising leadership Surrey became famed for brilliant fielding and catching, top-class bowling, and belligerent team spirit. G. A. R. Lock headed a squad of suicidally close fieldsmen on the leg side, Lock and J. C. Laker were the best pair of spin bowlers in England, A. V. Bedser the greatest fast-medium bowler of his generation, and P. J. Loader a fast bowler of England class. The batting revolved round P. B. H. May, the best batsman in England, who succeeded Surridge in 1957, and who built up a tradition of quick scoring without which many victories would not have been won.

**The Gentlemen v. Players Match.**—This, once the leading representative domestic fixture, was played regularly at Lord's from 1819 to 1962. For many years, the Gentlemen were no match for the Players, but the personal prowess of W. G. Grace (*q.v.*) gave the amateurs a period of success in the 1860s and 1870s. From then on supremacy varied with the heyday of great players, amateur and professional. Invariably the appearance of 22 of the leading cricketers in the same game produced high-class cricket with none of the tensions of intercounty competition and championship points. Ability was the hallmark of selection, and all the great cricketers at one time or another took part. The decision of the MCC and the counties in 1962 to abandon the distinction between amateurs and professionals meant the end of this famous fixture.

**The Oxford v. Cambridge Match.**—This has been played at Lord's since 1827. These two universities rank with the counties as first class and are the chief nurseries of amateur cricket. Until the outbreak of World War II, the match was one of the social occasions of the summer season in London, but with the raising of academic standards and the increased cost of a university education, many of the best schoolboy cricketers no longer went to the university, and competition for places in the eleven was accordingly less keen. Nevertheless the universities continued to supply players for the England eleven.

**Women's Cricket.**—Women first played in England in the 18th century and spasmodic references appear during the 19th century. In 1887 the first club, "White Heather," was formed and in 1888 two professional teams known as "The Original English Lady Cricketers" were in action. About the same time, women's cricket was first played in Australia and New Zealand.

In 1926 the Women's Cricket Association was founded after a successful cricket week at Malvern, Eng., and these weeks became an annual fixture. Representative fixtures soon followed and in 1933–34 the first team toured Australia and New Zealand. Australia paid a return visit in 1937. By the second half of the 20th century the Women's Cricket Association was a flourishing organization, responsible for the administration of the game in England and for organizing test matches home and away. The latter take place at regular intervals against Australia and New Zealand, and new ground was broken in 1960–61 with a first tour of South Africa, where the women's game began only in 1951.

## INTERNATIONAL CRICKET

The English introduced their national game wherever a pitch could be found and two teams collected. Cricket flourishes especially in east and west Africa, Ceylon, Hong Kong, Singapore, Canada, Brazil, and Argentina. But the firmest roots are in those countries which, with England, are members of the Imperial Cricket Conference, founded in 1909, and including Australia, the West Indies, New Zealand, India, and Pakistan, and South Africa until the latter's withdrawal from the Commonwealth in 1961. In 1965 the conference was renamed the International Cricket

Conference to permit the election, as full or associate members, of countries outside the Commonwealth, and the United States, Ceylon, and Fiji were elected associate members.

**Australia.**—Cricket began in Australia in the early 19th century and was competitive between clubs from the start. The first interstate match took place in 1856 between Victoria and New South Wales. By the end of the century South Australia was playing with them in a triangular competition for the Sheffield Shield. Queensland was the next to join, and Western Australia was accepted to membership after World War II. Despite the huge distances, all five states play one another home and away each season, but New South Wales and Victoria are the dominant teams.

The real foundation of Australian excellence is club cricket. Each state has an association of affiliated clubs which controls players and grounds. Clubs are graded and competitions are arranged for each grade. First-grade teams in which novices play with great cricketers are the recruiting ground for the state team. Perfect light, hard, true pitches, long hours of sunshine, and the fewness of first-class matches are some of the reasons why Australians are such good cricketers.

**South Africa.**—Cricket was brought to South Africa in the middle of the 19th century by British troops and was played in military and police centres of the Cape and Natal till 1889. Despite a delightful climate, interstate fixtures were made difficult owing to wide distances and sparse population.

In 1889 Sir Donald Currie offered a cup to the team which put up the best performance against the first English touring team. Kimberley won, and next year Transvaal challenged and beat them. Thus began the Currie Cup Competition which is South Africa's provincial championship. Before the turn of the century Cape Colony (as it then was) had entered two teams (Western Province and Eastern Province) and Natal had also joined. After World War I, a board of control became the ruling body for South African cricket. The three most powerful provinces are Transvaal, Western Province, and Natal.

**West Indies.**—The characteristics of West Indies cricketers are great keenness and genuine enthusiasm for the game, a natural ability to bowl, and a desire to hit hard and score fast.

The game has probably been played since mid-19th century, but the first intercolonial match took place in 1865 between Demerara (British Guiana) and Barbados. By the end of the century a triangular tournament between Demerara, Barbados, and Trinidad was being held. In 1926 a board representing all the islands was set up to control interisland competitions, and to organize foreign tours. One of its problems has been to agree upon a national captain, so intense is the rivalry between the islands.

After World War II air travel enabled Jamaica to play the other islands, and in 1956 Barbados, British Guiana, Trinidad, and Jamaica played a knockout tournament at Georgetown, which British Guiana won. In the 1960s these four competed annually in the Shell Shield Caribbean Tournament.

**New Zealand.**—The game was first played in 1841, and the first representative game was between Auckland and Wellington in 1860. In South Island the discovery of gold in Otago brought many Australians, who helped to spread the game, and the first of the annual fixtures between Otago and Canterbury took place in 1864. Canterbury and Wellington met for the first time in 1885.

The New Zealand Cricket Council was formed in 1894, thus fulfilling a long-felt want for management in such a scattered country. Each province has its own association, made up of delegates from affiliated clubs, and representatives of these serve on the council. The Plunket Shield (named after a former governor-general) is played for annually between Auckland, Wellington, Canterbury, Otago, Northern Districts, and Central Districts. The first English team visited the country in 1864, and others have gone at frequent intervals, but New Zealanders have fewer opportunities than others of seeing great players, and the expense of sending teams abroad is great, so the standard of play has not materially advanced.

**India.**—English settlers introduced the game and the army helped to popularize it. The first all-Indian club was the Oriental Cricket Club, for Parsees, formed in 1848. English professionals

improved the standard of play, and there was a gradual sinking of jealousies of the various races and creeds in the cause of cricket. In 1877 the first match between the Parsees and the Europeans in Bombay was played, and the Parsees showed such improvement that Parsee teams went to England in 1886 and 1888.

In 1906 the Hindus competed with the Parsees and the presidency (the Europeans) in a triangular tournament, and by 1912 this had become quadrangular with the advent of the Muslims. Pitches were uneven, grounds often agricultural, and gear crude, but enthusiasm was tremendous.

In 1926 the MCC sent their first team to India, and the princes began to pick their own sides—a sign that cricket was spreading. Since 1934 India has staged a national championship for the Ranji Trophy, with "The Rest" joining the quadrangular in 1937.

**Pakistan.**—Since partition in 1947, cricketers have had a difficult task of organization. An embryo test team was soon formed and during the first years of its existence it has had a good record. In an attempt to build up a cricket tradition and find reserves for the national eleven, the country has been divided into four groups for a championship for the Quaid-i-Azam Trophy.

## TEST MATCHES

**History.**—The first international or test match between sides of players chosen to represent the best cricket each country had to offer was played in Melbourne in 1877, when Australia beat England by 45 runs. Australia's success was repeated in 1882 at the Oval, London, in the game celebrated in the *Sporting Times* by the obituary notice announcing cricket would be cremated and the ashes sent to Australia, giving birth to the legend of the "Ashes," which became the popular objective in games between England and Australia. The ashes, kept in an urn at Lord's, were made from a stump burned on the England tour of Australia in 1883. For the rest of the century, the two countries met almost yearly, and with W. G. Grace in his heyday, England was generally too strong, though Australia had the greatest bowler of his era in F. R. Spofforth, and the first of the great wicketkeepers in J. McC. Blackham. Australia had a period of ascendancy at the turn of the century, the 1902 series producing thrilling cricket, with Australia winning by three runs at Manchester to which England replied with a one-wicket victory at the Oval.

In 1903 the MCC, determined to restore the prestige of English cricket, for the first time organized a team to visit Australia to recover the Ashes. This was a highly successful operation but the pendulum swung to and fro till the outbreak of World War I.

In the meantime new and worthy opponents for England were gathering strength. In 1894 the South Africans first went to England and their cricketers gained invaluable experience during two subsequent tours in South Africa, one by England and one by Australia. In 1905 the first MCC team to South Africa lost the rubber primarily because of googly bowling, which mastered English batsmen on the fast matting wickets. Such a triumph won for South Africa the right to test matches in England, and in 1907 they proved their ability to play England's best.

After World War I, England, Australia, and South Africa continued to play one another at regular intervals, and in 1928 the West Indies for the first time entered the test match arena. The 1931 New Zealand joined them, and in 1932 India followed. The result was a serious crowding of the fixture lists. England, with its reliance on county cricket for six days a week, was hardest hit, and life for the top players became a round of cricket and travel. Interest in test matches was stimulated in the 1930s by the introduction of radio commentary and by the advent of the correspondent whose object was news stories and off-the-field activities at the expense of straightforward cricket reporting. In 1930 test matches between England and Australia were increased to four days' duration.

England was slow to recover from World War I, and Australia dominated the test match scene for the first six years, because of the fast bowling of J. M. Gregory and E. A. MacDonald, the googlies of A. A. Mailey, and overwhelmingly strong batting and superb fielding. In 1926 England recovered the Ashes and held them for four years, during which their leading cricketers were opening

batsmen J. B. Hobbs and H. Sutcliffe, fast bowlers H. Larwood and M. W. Tate, and all-rounder W. R. Hammond.

In 1930 English crowds for the first time saw the new young Australian phenomenon D. G. (later Sir Donald) Bradman. Between 1928 and 1948 he scored 19 centuries against England and his average in all tests was 99.94 runs. On his first English tour he made 254, 334, and 232 in the tests, and these, with the slow bowling of C. V. Grimmett, were sufficient to win the rubber.

D. R. Jardine, captain of the next MCC team to Australia (1932-33), evolved the plan known as "body-line," with H. Larwood as chief protagonist. Bowling very fast and accurately at the leg stump, with a majority of fieldsmen on the leg side, he effectively curbed Bradman and his colleagues, and was largely instrumental in winning the rubber for England by four games to one (a "rubber" is any series of test matches—3, 4, or 5—between any two countries that are full members of the International Cricket Conference). The new technique, however, savoured so much of direct attack on the batsman that it caused a storm of protest and was subsequently outlawed by the MCC as being contrary to the spirit of the game.

The remaining Anglo-Australian rubbers until World War II were dominated on the Australian side by Bradman and another prolific run maker W. H. Ponsford as batsmen, and by the persistence and hostility of the slow bowling of Grimmett and W. J. O'Reilly. Australia won in 1934 in England and in 1936-37 in Australia. In 1938 a new English batting star L. Hutton made history with an innings of 364 at the Oval, which ensured a record victory by an innings and 579 runs.

Meanwhile England had had to strike its flag at home to South Africa, who won at Lord's in 1935 by 157 runs, for the first time. When the next MCC team toured South Africa in 1938, turf wickets were in common use, and the result was an unprecedented orgy of run-getting, culminating in an infamous final test match at Durban which was abandoned on the 10th day with the ground flooded by a thunderstorm, and England, with victory in its grasp, having to catch the ship home.

Between these tests against ancient rivals, England now sandwiched matches against the West Indies in 1928, 1933, and 1939, against India in 1932 and 1936, and against New Zealand in 1931 and 1937. In none of these was the home country really extended, though New Zealand forced a draw at Lord's in 1931. Return visits were paid to New Zealand after each of the Australian tours and to India in 1933. In 1934 an MCC team toured the West Indies, which had been for the first time to Australia in 1930-31.

In 1931-32 the South Africans toured Australia and came home via New Zealand for the first time, and in 1935-36 they received Australia. Hence the pattern of continuous cricket was already being evolved when war broke out in 1939.

**After World War II.**—Test cricket began again in 1946, and in every succeeding summer a touring side has engaged in test matches against England. Before the late 1960s Australia made the trip twice in every eight years, South Africa every five years, and the other countries at longer intervals. Pakistan was admitted to the international association in 1952 and first toured England in 1954. In 1965 South Africa and New Zealand each undertook a short tour in England, with three tests each. In 1966 the MCC announced a four-year cycle of tours, in which twin tours to England (by India and Pakistan, or by the West Indies and New Zealand) would alternate with single tours (by Australia or South Africa). The MCC has continued to travel to Australia every four years, and visits to other countries are a feature in two out of every three winters. The other members of the International Cricket Conference have gradually extended their fixtures.

Test matches last 30 hr. (six days in Australia and the West Indies and five days elsewhere), except by local agreement.

**Australia.**—As in the 1920s, the first few years after World War II were dominated by Australia. Bradman was still a tremendous force, and the team he led to England in 1948 was as strong as any in history, with K. R. Miller and R. R. Lindwall as one of the great fast-bowling combinations of all time. This team held its own in world cricket till 1953, winning three rubbers against England 3-0, 4-0, and 4-1, one against India 4-0, one against South

Africa 4-0, and one against the West Indies 4-1.

The first signs of a waning of power occurred when South Africa toured Australia in 1952-53 and drew the rubber 2-2. In 1953, at the Oval, Australia at last relinquished the Ashes held since 1934. In 1954-55 an MCC team in Australia won a resounding victory 3-1, largely because of the devastating speed of F. H. Tyson and the accuracy of J. B. Statham.

Australia took some time to recover from this defeat. The 1956 team in England won a good victory at Lord's but was twice caught on bad wickets at Leeds and Manchester, and lost the series. An abnormally wet summer provided a feast of wickets for off-spinner J. C. Laker, who at Old Trafford, Manchester, achieved the unprecedented feat of taking 9 for 37 (9 wickets for 37 runs) and then 10 for 53.

The Australian recovery began with a successful tour of South Africa in 1957-58 and continued with victory over the MCC in Australia in 1958-59. The next four series produced only 8 results with 12 draws in 20 matches, Australia retaining the Ashes by winning two rubbers in England and drawing two at home. Australia was beaten for the first time by the West Indies in the Caribbean in 1965.

Leading cricketers of this latter period were R. Benaud, a highly successful captain and all-rounder, A. K. Davidson, a left-handed fast bowler and hitter, and R. B. Simpson, captain, brilliant slip field and opening bat with W. M. Lawry in many big first wicket partnerships.

**England.**—England took some time to recover after World War II, but returned to top form in the 1950s and did not lose a test rubber between 1952 and 1958. After 1958 English teams were usually too strong for New Zealand, India, and Pakistan, had equality with South Africa, but in the 1960s lost four rubbers at home, two each to Australia and the West Indies.

After comfortable victories at home in 1946 against India and in 1947 against South Africa, England went down in 1948 to Bradman's Australians. The rot was temporarily stopped in 1948-49 in South Africa, but in 1950 the West Indies won their first-ever rubber in England. The corner was turned in Australia in 1950-51 when, after losing the rubber, England won the fifth test, and in 1953 recaptured the Ashes under L. Hutton, its first professional captain. This success followed home wins against South Africa in 1951 and against India in 1952. In the West Indies in 1953-54 England lost the first two Tests but rallied to save the rubber, and in 1956 retained the Ashes, v. Australia. South Africa achieved a drawn series on its own wickets, but in 1957 England overwhelmed the West Indies. After Hutton retired, England had brilliant batsmen in P. B. H. May, M. C. Cowdrey, and E. R. Dexter, while fast bowler F. S. Trueman was for many years a colourful figure who took a world record number of wickets (307) in test matches.

Now the tide turned again. In 1958-59 Australia regained the Ashes at home and went on to win two successive rubbers in En-

gland in 1961 and 1964 and drew two more at home in 1962-63 and 1965-66. England had easy home wins against India in 1959, South Africa in 1960, Pakistan in 1962, and New Zealand in 1965, but after winning a rubber for the first time in the West Indies in 1959-60, suffered overwhelming defeats when West Indies toured England in 1963 and 1966.

**South Africa.**—In 20 years after World War II South Africa contested eight rubbers against England and achieved its first win 1-0 in a three-match series in England in 1965. It had previously drawn the 1956-57 series in South Africa. Australia had always been invincible in South Africa, where the home side lost two rubbers in 1949-50 and in 1957-58, until 1966-67 when South Africa won the test series; but South Africa has done better in Australia, drawing series in 1952-53 and 1963-64. Against New Zealand, South Africa had an easy success in New Zealand in 1953-54 and played two drawn rubbers, home and away, in 1961-62 and 1963-64.

The application of the principle of apartheid to visiting sports teams had its bearing on test cricket, but in 1967 the South African government relaxed its law to permit coloured players to visit South Africa as members of white teams.

**West Indies.**—The West Indies reached world class after World War II and in the mid-1960s they were undoubted world champions. They owed their early success primarily to three great men—C. L. Walcott, wicketkeeper-batsman, E. D. Weekes, batsman, and F. M. Worrell, all-rounder—and to two young spin bowlers, S. Ramadhin and A. L. Valentine. They beat England in England for the first time in 1950 and held them to a draw in the Caribbean in 1953-54. A recession while new talent matured led to defeats against England, both home and away, but in the early 1960s Worrell's team, though narrowly losing a rubber, won the hearts of Australian crowds with their joyous cricket and at Brisbane took part in the only tied match in Test history. Worrell's final triumph was the defeat of England in England in 1963 and his successor, G. Sobers, holder of the record test score of 365 not out against Pakistan, led the West Indies to victory against Australia in the Caribbean and against England in England in successive years, by which time he was acclaimed the most versatile and gifted all-rounder of all time.

The West Indies has not yet been beaten by India, but Pakistan won a test in 1958 at Trinidad and a three-match rubber at home in 1958-59. Ironically New Zealand's first test win was against the West Indies in 1956 at Auckland.

W. W. Hall and C. C. Griffith were a formidable pair of fast bowlers, L. R. Gibbs a clever off-spinner, and C. C. Hunte, R. B. Kanhai, B. F. Butcher, and S. M. Nurse high-class batsmen.

**New Zealand.**—New Zealand won a test match against the West Indies in 1956 and two against South Africa in 1961-62 when it drew a rubber in South Africa. It has also toured England, India,

and Pakistan without success and has entertained at home all the test-playing countries except Australia.

**India.**—Between 1947 and 1966, India played 15 rubbers against all countries except South Africa and while being no match for England and Australia away from home, proved hard to beat on its own wickets. England was twice beaten in 1961-62 and India beat Australia once in 1959-60 and once in 1964. Other wins have been against New Zealand (three) and Pakistan (two). It has yet to win a match against the West Indies.

**Pakistan.**—Pakistan made an auspicious entry into world cricket by beating England at the Oval in 1954, Australia at Karachi in 1956 and the West Indies at Port of Spain in 1958. In Pakistan it beat the West Indies 2-1 in 1958-59 and other victories have been against New Zealand (two) and India (one). Two consecutive drawn series with India were played in 1954-55 and 1960-61, neither side winning a match.

**CRICKET**, an orthopteran insect of the family Gryllidae (see ORTHOPTERA), universally known because of the musical chirping of the males. There are about 1,500 species, varying in length from one-eighth inch to over two inches; all have thread-like antennae, jumping hind legs, three-jointed tarsi and two slender abdominal cerci. The forewings are stiff and leathery, bearing a stridulatory apparatus in the males of most species; the hind wings are flying organs, long and membranous when developed.

Most distinctive among the 16 subfamilies of Gryllidae are: the tree crickets (Oecanthinae), delicate, greenish insects with transparent wings; the field and ground crickets (Gryllinae and Nemo-biinae), stout-bodied, black and brownish species, which often excavate shallow burrows; the ant-loving crickets (Myrmecophilinae), minute, wingless, hump-backed insects living in ant nests; and the mole crickets (Gryllotalpinae), subterranean insects with greatly modified shoveling forelegs, cylindrical bodies, pointed heads and velvety coats of hairlike setae.

Crickets chirp by rubbing an upturned scraper on one forewing along a row of 50–250 teeth on the underside of the other forewing. The dominant frequency in the sound depends upon the number of teeth struck per second, and varies from around 1,500 cycles per second (c.p.s.) in the largest species to nearly 10,000 c.p.s. in the smallest. The sounds are produced as series of pulses, up to about 150 per second, each pulse corresponding to a wingstroke; behavioural significance lies in variations in pulse rate and rhythm. Most commonly heard is the calling song, which attracts the female; the courtship or mating song induces the female to copulate and the fighting chirps repel other males. Both sexes possess highly sensitive and directional auditory organs, located within oval slits on the forelegs. Cricket sounds are affected by temperature; the North American snowy tree cricket, *Oecanthus niveus*, is popularly known as the "thermometer cricket" because a listener can determine the approximate temperature (Fahrenheit) by counting the chirps sounded in 15 seconds and adding 40. Individuals of this nocturnal species synchronize their adding 40. Individuals of this nocturnal species synchronize their adding 40. Individuals of this nocturnal species synchronize their adding 40.

Most female crickets inject their eggs into the soil or into plant stems through long, slender ovipositors; the oviposition slashes of tree crickets often seriously damage berry canes and small twigs. Subterranean crickets lack long ovipositors, but place their eggs in underground chambers, sometimes along with plant materials upon which the newly hatched nymphs later feed. In northern latitudes most crickets mature in fall. They overwinter as eggs, which hatch into nymphs the following spring. A few burrowers overwinter as nymphs and mature in early summer. There are 6–12 nymphal molts, and the adults usually live 6–8 weeks.

Crickets vary in feeding habits, and many are omnivorous. Several species frequent human dwellings and refuse heaps, most notably the straw-coloured house cricket, *Acheta* (formerly *Gryllus*) *domesticus*, and the decorated cricket, *Gryllodes sigillatus*. Subterranean species subsist largely upon roots and are quite injurious when abundant in crops, gardens and newly reforested areas.

House and field crickets are reared and sold by the millions as fish bait in the United States; they are also important laboratory animals in many parts of the world. In the Orient, the males are caged for their songs, and cricket fighting has been a favourite sport in China for over a thousand years.

**CRICKLADE**, a market town in Wiltshire, Eng., is 8 mi. N.W. of Swindon by road. Pop. (1951) 1,945. Its situation at a crossing of the upper Thames, where it first becomes navigable, gave it an early importance; the Roman Ermine street from Silchester to Cirencester passes through the parish. In A.D. 69 the emperor Vespasian established a centre of reconnaissance there and coins of Vespasian, Flavius Honorius and Galerius Valerius Maximinus have been found. Alfred the Great made Cricklade a burgh in 871. Early in the 10th century it possessed a mint and examples of its coins date from Aethelred II to William II (Rufus).

During the 12th century Matilda (q.v.), in flight from Stephen, was befriended by the townsfolk to whom her son, Henry II, granted a charter in 1155. In the reign of Henry III a hospital dedicated to St. John the Baptist was founded at Cricklade, and placed under the government of a warden or prior. Cricklade was a borough by prescription at least as early as the Domesday survey, and returned two members to parliament from 1295 until it was disfranchised by the act of 1885. The borough was never incorporated, but certain liberties, including exemption from toll and passage, were granted to the townsmen by Henry III and confirmed by successive sovereigns. In 1257 a grant was made for a Thursday market and an annual three-day fair at the feast of St. Peter ad Vincula. The market, which was subsequently changed to Saturday, was at one time much frequented by grain and cattle dealers. During the 14th century Cricklade formed part of the dowry of the queens of England. In the reign of Henry VI the lordship was acquired by the Hungerford family, and in 1427 Sir Walter Hungerford granted the reversion of the manor to the dean and chapter of Salisbury cathedral to aid toward the repair of the belfry.

St. Sampson's church, on the site of a 9th-century Saxon building, is cruciform and mainly Perpendicular. The small church of St. Mary has an Early English tower, Perpendicular aisles and a Norman chancel arch.

There is a creamery and canning factory outside the town, which also has a glove factory and rural hand potteries. It is the only parish council in the United Kingdom to bear arms. With Wootton Bassett it now forms a district council. (CL. A. H.)

**CRIEFF**, a small burgh in Perthshire, Scot., and the capital of Strathearn, 18 mi. W.S.W. of Perth by road. Pop. (1961) 5,771. It occupies the southern slopes of a hill on the left bank of the Earn and is a tourist centre for the Perthshire highlands. Anciently called the Burgh of Regality of Drummond, its charter is said to date from 1218, and it was the seat of the courts of the earls of Strathearn till 1747, when heritable jurisdictions were abolished. A stone cross with runic carvings, believed to be of the 12th century, and an octagonal 17th-century market cross stand

in High street, but the great cattle fair, for which Crieff was once famous, was removed to Falkirk in 1770. It was probably in connection with this market that the "kind gallows of Crieff" acquired their notoriety, for they were mostly used for the execution of Highland cattle stealers; the timber is now in the tolbooth (1665), the present town hall. Among the principal buildings are Morrison's academy (1860), a school

MALE FIELD CRICKET (*Gryllus assimilis*) WITH FOREWINGS LIFTED IN STRIDULATION

BY COURTESY OF RICHARD D. ALEXANDER

for boys and girls, and Strathearn house, a hydropathic establishment on a hill sheltered by the Knock of Crieff (911 ft.). Tourism and agriculture, with milling, are the main industries. Drummond castle, about 3 mi. S.S.W., is known for gardens planned by the 2nd earl of Perth (d. 1662) and laid out in terraces illustrating Italian, Dutch and French styles. The keep dates from 1491, but the present structure was erected after the Jacobite rebellion.

**CRILE, GEORGE WASHINGTON** (1864–1943), U.S. surgeon who made notable contributions to the study of surgical shock, was born in Chili, O., on Nov. 11, 1864. He graduated from Ohio Northern University and Wooster University Medical School and studied in London, Vienna, and Paris. He was distinguished as a surgeon of the respiratory system, developed the nerve-block anesthesia, and was an early user of blood transfusion, for which he devised a method of direct linkage. During World War I Crile was professional director and consultant of a U.S. base hospital in France. He also founded the Cleveland Clinic Foundation. Crile died in Cleveland, O., on Jan. 7, 1943.

Among Crile's many published works were *Surgical Shock* (1897); *Surgery of Respiratory System* (1899); *On the Blood Pressure in Surgery* (1903); *Hemorrhage and Transfusion* (1909); *Nature of the Emotions* (1915); *Notes on Military Surgery* (1924); *A Bipolar Interpretation of Living Processes* (1925); and *Diseases Peculiar to Civilized Man* (1934).

**CRILLON, LOUIS DES BALBES DE BERTON DE** (1541–1615), French soldier whose knightly courage caused him to be regarded as the Bayard of his times, was born at Murs, in Provence, on March 5, 1541. He began military service under François, duc de Guise, and distinguished himself in the taking of Calais from the English (1558) and in the wars against the Huguenots from 1562 to 1569. A knight of Malta from 1566, he fought against the Turks at Lepanto (1571) and was chosen to bring the news of the victory to the pope. Disgusted by the massacre of St. Bartholomew's Day (1572), he nevertheless served against the Huguenots at La Rochelle (1573). He accompanied the duc d'Anjou to Poland and remained loyal to him when he returned to France as Henry III and had to contend with the League. Invited by Henry to kill Henry de Guise, he offered to fight a duel but refused to act as an assassin. Supporting Henry IV likewise against the League, he fought at Ivry (1590) and served in the siege of Paris. After the Savoy campaign of 1600, he retired to private life, with little reward save compliments from his king. He died in Avignon on Dec. 2, 1615.

**CRIME.** In modern civilized societies only violations of rules promulgated and enforced by agencies of the government technically are crimes. Although crime is sometimes viewed in a very broad way as the violation of any important group standard or as the equivalent of antisocial, immoral and sinful behaviour, much immoral behaviour is not covered by the criminal law, and violations of some laws included in the criminal code are not regarded as immoral or even antisocial, or are so regarded only by a small portion of the population. Labour unions, professional organizations and many other groups within a society establish rules for their members and provide penalties for infractions, but such rules are not part of the criminal law. No matter how immoral, disgusting or harmful an act may be, it is not legally a crime unless it is covered by a law which prohibits it and prescribes punishment for it.

The concept of crime therefore involves the idea of a public as opposed to a private wrong, with the consequent intervention between the criminal and the injured party by an agency representing the community or public as a whole. In this view, crime is the intentional commission of an act deemed socially harmful or dangerous and usually specifically defined, prohibited and punishable under the criminal law. Difficulties arise from this definition because of the practical problems often involved in determining whether or to what degree an act is intentional, because some offenses known as "strict liability offenses" (see **CRIMINAL LAW**) are punished as crimes even though they may be unintentional, and because there are wide differences of opinion concerning what is socially harmful and dangerous. Legislatures are sometimes influenced by powerful vocal minorities to enact legislation which

benefits only a certain group or which reflects only its views of what is right and wrong. Such laws may be contrary to the general good and opposed to the moral convictions of the general public. In short, laws themselves may be immoral. For example, violations of anti-Semitic laws in Nazi Germany or of anti-Negro laws in the United States constitute crimes, in that they are violations of laws prohibiting such acts and prescribing punishment for them; but the morality of such laws is a different matter.

**Varying Attitudes and Practices.**—Conceptions of crime vary so widely from culture to culture and change with time to such an extent that it is extremely difficult to name any specific act universally regarded as criminal. Treason or disloyalty to the group, especially in time of conflict or war, is perhaps one of the most universal and among the first acts to have been recognized as a public wrong. Other types which emerge very early in human history are sacrilege or the violations of supernatural taboos and incest which, although almost universally condemned in primitive and modern societies, is differently defined in different cultures. Adultery, fornication, prostitution, homosexuality and other disapproved forms of sexual expression are handled in many ways in contemporary societies and are sometimes covered by the criminal code and sometimes not. (See **SEXUAL BEHAVIOUR: Legal Aspects.**) Murder is a recognized crime in all civilized societies, but primitive peoples and folk communities within civilized societies may treat the killing of a human being as a relatively private matter to be dealt with by the kinship groups involved. The blood feud (q.v.) is an example of this. The deliberate killing customary in some primitive societies, such as infanticide, head hunting, cannibalism and the killing of very old persons, would be classified as murder in civilized societies.

If crime is viewed only as violation of criminal codes promulgated and enforced by the state and its agencies, however, it can hardly be said to exist in primitive societies in which political and legal institutions are undeveloped. In such societies conduct is largely controlled by customs and standards shared by virtually all members and serious violations are relatively rare. When they do occur they may be handled as private rather than public wrongs by the persons, families or kinship groups directly involved. In more complex preliterate societies the conception of a public offense (crime) emerges more clearly and offenders may be summoned before the headman or a council of elders, who hear the case and fix the punishment in accordance with the traditions of the group. In general it may be said that primitive peoples more often than civilized peoples, handle infractions of social norms as torts (private wrongs) rather than as crimes; that they pay less attention to the state of mind or intention of the offender and that responsibility is more often collectively assessed than is the case in modern criminal law where criminal guilt is generally regarded as strictly personal. While practices vary widely, the manner of determining guilt among preliterate peoples is usually very different from that of the contemporary criminal trial and involves much that has nothing to do with the actual evidence such as ritual oaths, ordeals and various magical devices.

In modern industrial society there has been an enormous proliferation of criminal laws designed to protect property rights. The conception of property and the nature of property crimes have changed enormously with the evolution of capitalist economic institutions such as those of credit, large-scale business and industry and the modern publicly owned corporation. With this expansion of criminal law in economic and certain other areas there has been a compensating tendency for laws relating to religious observances and to certain kinds of sexual behaviour to disappear or not to be enforced. Crime in contemporary civilization is thus a far different matter from crime in even the more advanced primitive societies. The criminal codes of modern nations are enormously complicated, growing bodies of written rules and doctrines, most of which are unknown to the average citizen. Offenders are detected, brought to court, tried, convicted and punished by professionals especially trained for their particular functions, and in the meantime other professionals, the criminologists, investigate the causes of crime and examine the ways in which correction and prevention are handled. Academic students of

crime, judges, prosecutors, defense lawyers, police, prison officials, sociologists, social workers, psychiatrists and psychologists, all have different perspectives and offer different suggestions.

The dominant conflict of views in the field of penology is between those who put their faith in severe punishment in the belief that this will prevent the criminal from repeating his crimes and also serve as a deterrent to others and, at the other extreme, the school of thought which emphasizes the futility of punishment and the evil effects of prison life. The advocates of this latter position often conceive of the criminal as a victim of social and psychological forces outside his control. They contend the criminal should be regarded as though he were mentally ill and instead of being made to suffer for his crimes should be treated for his illness. Punishment is said to be an expression of vengeance based upon a discredited psychological doctrine of free will and should therefore be eliminated.

A compromise position located between the two extremes seems to be the one toward which most of the nations of the world are moving. This position rejects the idea that punishment should be abolished and insists that moderate and just punishment itself has rehabilitative value. Instead of severity it stresses swiftness and certainty of punishment, which it regards as having more deterrent effect and as increasing the opportunity to reform the criminal. Treatment without punishment is regarded as applicable only to the mentally ill and the very young. The evils of prison life are admitted but it is proposed to mitigate them by imposing shorter sentences, by using probation, fines and other substitutes for imprisonment, by improving conditions within prisons and by experimenting with new kinds of prisons and rehabilitative techniques. It is also commonly recognized that some criminals must be incarcerated for long periods of time, not so much for the sake of severity as for the protection of society.

During the last several centuries use of the death penalty has declined and it is under attack in many of the jurisdictions that still retain it, as do Great Britain and most of the states of the United States. Corporal punishment, torture, banishment and other more brutal forms of punishment have largely been abandoned in favour of imprisonment for almost all serious crimes and fines for the lesser ones.

Public opinion in regard to the punishment of criminals is divided and vacillating. Rising crime rates invariably create a demand for greater severity of punishment, restoration of corporal punishment or more frequent infliction of the death penalty. When legislatures respond to these pressures, however, public opinion often develops and may prevent the actual imposition of the increased penalties. Low crime rates tend to be associated with lenient and liberal treatment of criminals, but it is difficult to say whether the lenient treatment of offenders reduces crime or whether a favourable situation in regard to the amount of crime reduces public hostility toward offenders and causes them to be handled more gently.

### UNITED STATES

**Identification of Criminal Acts.**—In the United States statutory prohibitions vary from one political jurisdiction to another and from time to time within a given jurisdiction; adultery, sodomy and gambling are a few examples of acts that are prohibited in some places and tolerated in others. Similarly, traffic regulations are notoriously inconsistent in different states and municipalities. Nevertheless, statutes in the various U.S. states exhibit considerable uniformity in outlawing specific acts ranging from such minor offenses as disorderly conduct and vice to such relatively severe offenses as larceny, assault, robbery, homicide and treason.

While statutes define crime, it remains for police and courts to take appropriate judicial measures against persons accused of violating these statutes. Conviction of a crime in a criminal court means that, officially at least, the offender has committed a designated criminal act, that he has been assigned the legal status of a criminal, and that in most cases he has been deprived of some

of the prerogatives of citizenship, such as the right to vote or to hold public office. (These rights, however, are sometimes restored after punishment or other corrective action has been consummated.)

Thus specific instances of criminality are identified by the judicial process. If this process is not applied uniformly and efficiently, violations of statutes may infrequently result in criminal convictions. For example, it has been estimated that only 35 persons are committed to penal institutions for every 1,000 offenses known to the police. Other cases, of course, are placed on probation, given fines, or sentenced to short jail terms. But the disparity between the number of known offenses and the number of court convictions is one of the most difficult crime problems in the United States.

Law violators may avoid punishment or other official controls for several reasons. Many offenses escape detection. It is sometimes hard to tell whether objects have been lost or stolen, for example, and even violent offenses such as assault or homicide may be difficult to identify. When death is surrounded by unusual circumstances, investigation may fail to determine if it is due to suicide, homicide or "natural causes." Detection of crime is especially troublesome when the victim is feeble-minded, psychotic, intoxicated or otherwise irresponsible.

Methods of criminal investigation and identification have shown much improvement in modern times but law-enforcement agencies often fail to obtain the public support and co-operation that is essential for effective use of the judicial process. Many known offenses are not reported to the police. When the reputation of the victim is likely to be endangered, as in certain sex offenses, attempts at concealment commonly occur. Or the victim may be reluctant to report certain offenses because he, too, is involved in law violations, as is frequently the case among victims of "confidence games" and "shady deals." Again, the victim may refuse to co-operate with the police if the offender is willing to make restitution for any damages resulting from the offense.

Offenses that are reported may not be solved by the police. Although more than three-fourths of reported rapes, assaults and murders are "cleared" by arrest, this is true for only about one-fourth of larcenies and burglaries. Even after arrest a number of offenders avoid court convictions; about three-fourths of the persons arrested for burglary and larceny are found guilty, while approximately half of those charged with rape, assault or murder are convicted. Finally, some persons—children and the insane, for example—do not ordinarily come under the purview of criminal courts regardless of the severity of their offenses, because they are not considered to be legally responsible for their actions.

**Trends and Frequencies.**—The main source of information on nationwide crime is the *Uniform Crime Reports*, issued semi-annually by the Federal Bureau of Investigation (q.v.). These reports are compiled from data contributed voluntarily to the bureau by numerous law-enforcement agencies. They provide statistical information on offenses known, arrests made and guilty verdicts obtained. The reliability and comprehensiveness of the data are impaired, however, by local and regional variations in definitions of terms, lack of efficient records systems in some agencies, and the fact that reports of local agencies to the bureau are not compulsory or subject to other legal controls.

Estimates indicate that 2,500,000 offenses occur annually in the United States. Approximately 200,000 prisoners are confined in state and federal correctional institutions. Another 100,000 are held in various jails and about 40,000 in juvenile institutions. The number of prisoners is increasing by about 4,500 annually, and the cost of construction for housing them is perhaps \$45,000,000 per year. The use of probation and parole is increasing even more rapidly, but probably at less cost. Estimates of crime costs vary from \$10,000,000,000 to \$20,000,000,000 per year.

Moreover, crime rates appear to be increasing considerably more rapidly than the rate of population increase. This is especially true of most property offenses. Homicide rates appear to be fairly stable. Aside from traffic violations, drunkenness is the single offense with the highest frequency of arrest. Of major crimes, larceny seems to occur most frequently; burglary, auto

theft, assault, robbery, rape and homicide follow in that order.

**Variables Associated with Criminality.**—Numerous studies show that crime varies according to the social and cultural characteristics of a community. Consistent regional differences in criminality can be noted: New England states have relatively low rates for nearly all types of crime; southern states have the highest rates for assault and homicide; Pacific coast states have the highest rates for robbery, burglary and larceny. Generally, large cities have higher crime rates than small cities and urban areas have higher rates than rural areas, although crimes such as rape and homicide do not appear to follow this pattern.

Similarly, crime rates vary within a given area or community according to the social and cultural characteristics of the constituent neighbourhoods. The highest rates are frequently found in deteriorated urban areas where there is extreme poverty and unemployment, where change of residence is frequent and inhabitants have few ties with the community, where diverse cultural and ethnic groups are temporarily intermingled, and where parents are often either negligent or unreasonable in relations with their children. Gang violence and juvenile delinquency are also concentrated in such areas. These are the neighbourhoods in which legitimate avenues to success and achievement are greatly restricted and contacts with traditions of criminality are prevalent.

In addition, crime rates vary according to the social and psychological traits of individuals. Thus, males have higher rates than females, unskilled labourers have higher rates than skilled workers or professionals, Negroes have higher rates than whites, members of the lower socioeconomic classes have higher rates than members of the middle or upper classes, psychopaths have higher rates than those who are emotionally healthy, etc. These traits, of course, are not major causes of crime, but they are often closely related to more fundamental social and cultural factors.

Of serious crimes such as auto theft, robbery, burglary, and larceny, the rates among persons 16 to 25 years of age are considerably higher than they are among other age categories. These offenses comprise 95% of major crimes and are characterized by frequent repetition on the part of a single offender.

**Organized Crime and Racketeering.**—After World War I there was in the United States a spectacular growth of organized crime which assumed control over such tremendously profitable activities as gambling, bootlegging, bookmaking, the numbers racket, slot machines, narcotics traffic, prostitution and a variety of "protection" devices. Since segments of the American public have been willing to support organized crime by patronizing a variety of these illegal businesses and recreational activities, which are frequently highly organized, gangsters have attempted, often successfully, to exert political influence on all levels of government to prevent interference by the police and the courts. (See also **CRIMINOLOGY: Causation.**)

**White-Collar Crime.**—Although crime is commonly regarded as primarily an underworld activity, certain kinds of criminal behaviour occur also among respectable members of the community. White-collar crimes are committed by persons of respected occupational, economic or social status in the pursuit of their occupational activities; the offenses generally involve swindles, frauds and duplicity in financial dealings. (See also **EMBEZZLEMENT; FRAUD.**)

**Crime Control.**—Attempts to curb the rising crime trend involve both suppressive and preventive measures. To suppress crime the range and number of activities that come under the scope of criminal law has increased; so has the number of crimes defined by statute. No doubt, some of the increase in the crime rate is a result of these changes. Also, there has been an increase in the number of police organizations on all levels of government (see **POLICE**), and the co-ordination and consolidation of their services are receiving widespread attention.

Prevention devices include a variety of guidance services, clinics, clubs, camps and other institutions. Several states have established prevention bureaus to work with local communities on a consultant basis. The children's bureau in the federal department of health, education, and welfare has initiated preventive services and co-ordinated efforts on a nationwide basis. (See also

**CRIMINOLOGY: Prevention; JUVENILE DELINQUENCY.**)

In the final analysis, however, the public gets the kind of crime control it demands and is willing to support. If laws are regarded as outmoded, if citizens desire that laws be enforced only at certain times and places, if they demand preferential treatment, and if they place supreme value on wealth and power regardless of the way in which acquired, then, of course, they cannot expect the agencies of crime control to enforce laws or to supervise activities with any degree of efficiency, uniformity or impartiality. This is the major crime problem. (C. C. Se.)

## WESTERN EUROPE

**Changing Concepts of Crime.**—Christianity had a profound influence on the attitude toward crime in medieval Europe. It was thought necessary for criminals to be brought to repentance before being executed and the practice of torture arose from a legal prohibition to execute one who had not confessed (see **TORTURE**). Another factor was the need to build up a strong central government. Acts against the church and the person and power of the king and his officers became crimes, punishable by death. As central governments became more powerful, legislation against private crime increased, many new crimes were designated, and a distinct body of criminal law slowly evolved.

With the emergence of modern states in the 16th century, the accompanying economic revolution and the religious upheavals were reflected by great increases in the types of crime against which legislation was passed. Inflation and the breakdown of the medieval rural economy swelled the ranks of the unemployed in all of the more economically advanced countries of Western Europe and the penalties for vagabondage became increasingly severe (see **POOR LAW**).

The lawlessness and corruption associated with the 18th century is partly explained by the growth in population, inadequate police systems, and increasing prosperity that invited crimes against property. The growth of the banking system led to extensions of legislation against forgery; the growth of trade, to legislation against new crimes such as adulteration.

Gradually humanitarian feeling mitigated against the extensive use of the death penalty and resulted in reform of the prisons (see **CAPITAL PUNISHMENT; PRISON**).

By 1900 the dominant type of crime was urban property crime committed by young men. There were international rings of smugglers and jewel thieves. The disorganization of the social structure resulting from World War I was accompanied by an appreciable increase in crime, especially juvenile crime, together with new crimes associated with food rationing and price racketeering. Later the world-wide depression drove many persons to crime.

**The Effects of World War II.**—Although there are many variations in the penal codes, definitions of crime and of criminal responsibility, and administration of justice in the countries of Western Europe, their systems of crime prevention and control can be regarded as relatively homogeneous. This is not surprising, considering the socioeconomic conditions and cultural traditions which the countries concerned have in common.

It should be added that methods of collecting and recording data about crime also vary; this factor contributes many difficulties to the comparative study of crime in the different countries.

The following facts concerning selected countries in Western Europe are taken from the official crime statistics and the figures given are crime rates (frequencies), i.e., the number of offenses, persons, or convictions per 100,000 population. (Absolute figures are stated in parentheses.)

In the period just before World War II a country representing a relatively low crime rate was Norway, which had a rate of 300 (3,600 convicted men per year). In this period Belgium had the highest rate with approximately 600 (27,000 convictions per year). Denmark and England and Wales occupied a middle position with 400 (5,600 and 69,000 convicted men per year respectively). Switzerland was on the same level, 400 (18,000 convictions per year). The war saw an increase in crime in all countries except

Switzerland. This development was most conspicuous in Denmark. In Switzerland the crime rate fell rapidly between 1937 and 1940; since then it has increased, but without reaching the previous level of 400.

In the first decade of the postwar period there was a falling off in crime in all the countries of Western Europe, though it was not equally pronounced in all of them. In the mid-1950s the development reached a stage at which the direct consequences of World War II appeared to have ceased.

**From 1955 Onward.**—The International Criminal Police Organization (*q.v.*), better known as Interpol, publishes statistics on "the volume of crime," crimes known to the police, and on "persons responsible for offenses," *i.e.*, persons arrested (as opposed to persons convicted).

In addition to police statistics most countries produce court statistics. The latter provide a much better description of the different types of crimes and criminals. However, since the courts are dealing with only a part of the total amount of crimes (especially with the most severe offenses) this type of information has not, generally speaking, the same importance as police statistics if the widest possible picture of crime is required.

Police statistics from 1955 onward showed a clear decline in the total amount of crimes reported in Finland and clear increases in England and Wales, France, and Sweden. There was a rise in the volume of crime in Austria, Denmark, and the Netherlands. In the Federal Republic of Germany (West Germany) the development could be pictured by a graph assuming the shape of an inverted U, with 1960 as the peak year after which there was a drop in the number of persons arrested.

Court statistics (convictions) showed a strong rise in England and Wales and Norway, rather stable conditions in Belgium, and a decline in Denmark.

The best picture of the trend is obtained when the different categories of crime are studied separately. But it must be borne in mind that such comparisons on the international level are, as already mentioned, fraught with difficulties. It appears from police statistics that in all the countries under consideration there has been a relatively unchanged rate for sexual offenses; this also holds true for the rate for willful murder in the same countries apart from France, where considerable fluctuations were noted. The volume of serious thefts showed increases of varying degrees. As far as simple theft is concerned, there has been a general upward trend which has been most conspicuous in England and Wales, Denmark, West Germany, and the Netherlands. However, in Austria, the rate for simple theft has shown a slight drop. The rate for fraud has been rising in England and Wales, France, and Sweden, but declining in Austria, Denmark, West Germany, and the Netherlands.

The trends within the various countries have, as stated above, been relatively homogeneous. This does not mean, of course, that countries' crime rates are the same; the levels may differ considerably from country to country. Thus, to give a few examples, in the 1960s the rate for willful murder was under 1 per 100,000 in the population in Denmark but was just over three times as high in the Netherlands. The rate for sexual offenses was about 15 in Finland but nearly eight times higher in West Germany (over 100). The rate for serious theft was about 40 in France but nearly six times higher in Austria (over 200), whereas the rate for simple theft of 500 in Austria was about one-fifth of Sweden's (over 2,000). Finally, the rate for fraud was about 15 in England and Wales but 300 in West Germany. It should be added that the different levels merely indicate the relative numbers of reported offenses. Obviously the true picture of total crime (known and unknown) may look quite different.

**Trends in England and Wales.**—The development of crime in England and Wales was typical of the countries under review. The total number of crimes has shown a marked increase of four-fifths—from a rate of 292 in 1955 to about 550 in the 1960s. This rise was mainly due to an increase in crimes against property. Offenses against property connected with violence rose two and one-half times to over 100, whereas offenses against property without violence rose by three-quarters, from 200 to 350. Violence

against the person increased sharply, the rate rising nearly threefold to over 40. As far as sexual offenses are concerned, the trend has been more or less stable; the rate was 16 in 1955 and 15 in the 1960s. The stated rates concern persons tried on indictment and persons dealt with summarily, but more or less similar tendencies are to be found in the other statistical sources.

**Juvenile Delinquency.**—Since "juvenile delinquency" is variously interpreted in Western Europe, comparisons between countries may be more dubious than comparisons of adult crime. Nevertheless, studies of juvenile delinquency may be seen as indications of the trends within each country. Some data regarding five countries in Europe may serve as an illustration. Since the general downward trend of crime in the first decade after World War II was not apparent in the youngest age groups in the countries under review, the following covers the whole postwar period.

In Belgium the number of convicted males of 16 to 20 years of age has been fluctuating, the rates moving up and down between about 550 and 950 per 100,000. The first outstanding maximum in 1949 was followed by a decrease, which in 1955 brought the rate down to its lowest point. A second peak was reached by 1959; but since then the trend has been downward.

In Denmark changes in policy regarding crime and in registration practice make comparisons of the rates before and after 1960 difficult. The postwar years brought a drop from rates of between 1,500 and 1,600 to rates of about 1,200. From 1961 the rates have been about 50% higher. There is no indication of a similar trend among men in the 21- to 24-year-old age-group, so it is most doubtful whether the apparent increase of crime among juveniles is a real one or simply a consequence of the changes in the administration of the law and the methods of registration.

In England and Wales a marked increase in juvenile delinquency appeared after the mid-1950s. For 8- to 12-year-old boys convicted of indictable offenses the rate rose by two-thirds to over 1,600. In the 14- to 16-year group the rate nearly doubled to almost 3,000, and for the group aged 17 to 20 the rate increased two and one-half times to about 2,500. It should be added that crime was increasing in the older age-groups, too, so the trend was almost the same among the 21- to 29-year-olds, and was also markedly increasing, but less steeply, among older groups.

In Norway the rates for juvenile delinquents (aged 14 to 21) found guilty remained at almost the same level until the beginning of the 1950s (a rate of about 600). After 1954, however, the annual rate increased two and one-half times by 1961. But in the following years the rates dropped slightly. Similarly in Switzerland the number of convictions in the 14- to 19-year age-group remained at the same level, corresponding to rates of between 400 and 500, until 1957. For the subsequent period the number rose, but not to more than slightly over 700.

One may conclude that no general tendency regarding juvenile delinquency in Western European countries stands out. In some countries the frequency of juvenile offenders remained on the same level, in others it has been more or less increasing since about 1950. One common trait should be mentioned: in all countries automobile thefts have displayed a strongly upward trend, in most cases parallel to the increasing number of registered motor vehicles. There is an important qualification to the above crime rates: the different levels of juvenile delinquency in the various countries do not necessarily reflect real differences in the relative numbers of juvenile offenders; rather they may—at least to some extent—be seen as indicative of important national differences in the ways of dealing with juvenile offenders. (See also JUVENILE DELINQUENCY.)

**Female Crime.**—The number of female offenders make up only a fraction of that of male offenders. In the 1960s their ratios varied in four of the countries under review, where applicable data on female crime exist, between 1:4 (Belgium) and 1:9 (Denmark and Norway). Because of the small numbers the trends in female crime usually show more irregularities than those concerning men.

**Seriousness of Postwar Crime.**—The question of a possible aggravation of crime during and after World War II is often raised. However, no reliable index of the seriousness of the regis-

tered offenses or the dangerousness of the arrested offenders is available. Using such indicators as the length of sentence, the murder rate, the rate of other crimes of violence, the rate of malicious damage to property, it can be stated that during the war crime was aggravated seriously in a number of countries, especially in those occupied by foreign troops. However, after the war no serious symptoms of a general aggravation of crime have been disclosed, perhaps with the exception of the very marked increase of crimes of violence in England and Wales. The murder rate was fairly stable or decreasing in all the countries studied; in France, the only exception, there were great fluctuations but no clear signs of an increase. Only a few countries have published data on malicious damage; they do not show a general increase, but they reveal great variations that seem to stem from the low rate of reporting of such offenses and the low rate of convictions obtained for them.

**CRIMEA** (KRYM or KRIM), a large peninsula, known anciently as the Tauric Chersonese, lies between the Black Sea and the Sea of Azov, which are separated by the narrow Strait of Kerch (Kerchenski Proliv) at the eastern end of the Crimea. The peninsula (Krymski Poluostrov) is coterminous with the Crimean (Krymskaya) oblast of the Ukrainian Soviet Socialist Republic. Pop. (1959) 1,201,517. Area 9,884 sq. mi.

**Physical Geography.**—The peninsula is connected to the mainland by the 5–14-mi.-wide Perekop Isthmus, the scene of many battles for the control of the Crimea and crossed since ancient times by a ditch and earth bank. Between the Crimea and the mainland lies the Sivash, or Putrid Sea. The Sivash is shallow and is separated from the Sea of Azov by the remarkable 70-mi.-long sandspit known as the Arabatskaya Strelka, along the eastern shore of the Crimea.

The Crimea itself falls into three regions. The northern and central parts comprise a level plain (about 75% of the peninsula), sloping down gently from south to north. This is dry steppe on black earth and chestnut soils, with very little surface water. The intermittent rivers mostly dry out in summer. The second region is the Kerch Peninsula (Kerchenski Poluostrov) in the east, consisting of low hills, rich in iron ore, and with many mud "volcanoes." There, too, is steppe vegetation. The third region is made up of the Alpine fold mountains of the south, which form three chains, parallel to the southern coast. These chains, known as the Crimean Mountains (Krymskiye Gory), are successively higher to the south, all with steep-faced southern slopes and more gentle northern slopes. The highest southern range consists of flat-topped limestone blocks, known as *yaily*, which rise to 5,069 ft. in Roman-Kosh. This range drops steeply to the sea, where there is a narrow coastal plain, broken by cliffs and headlands. The mountains have a luxuriant and varied forest vegetation of oak, beech, hornbeam, maple, and other species. Many exotics have been introduced, such as cypress, oleander, almond, and myrtle,

together with palms and other subtropical plants.

The climate of the northern part is dry, with 12–14 in. of rain annually, and continental, although modified by surrounding seas. January temperatures are just below freezing and warm spells are common. The southern coast, sheltered by the mountains from cold northern air, has a mild, Mediterranean type of climate. Rainfall there and on the mountains is 20–25 in. a year.

**History.**—The first settled occupation of the Crimea was perhaps by the Cimmerians (q.v.) about 1000 B.C. In the 7th century B.C. the Scythae conquered the steppe area, but the kingdom of the Cimmerian Bosphorus (q.v.) survived in the Kerch Peninsula, where it came under strong Greek influence. From the 5th and 4th centuries B.C. onward the Greeks established colonies along the Crimean coasts, the most important being at Chersonesus, Heracleotica, near the modern Sevastopol, and Panticapaeum, where Kerch now stands. These colonies, which came under Rome in 15 B.C., survived the series of invasions by eastern nomadic hordes who in turn occupied the steppe. In the 10th century A.D. these cities fell to Prince Vladimir of Kiev, but Kiev was unable to retain the Crimea, which came under the Polovtsy (Kumans) of the steppe and later under the Tatars. In the 13th century the Genoese established "factories" along the coast, which remained until the conquest of the area by the Turks in 1475. Inland a remnant of the Tatar Golden Horde, owing nominal suzerainty to the Sultan, had their capital at Bakhchisarai (q.v.). These Tatars made frequent raids on the Muscovite state.

In 1774, by the Treaty of Kuchuk Kainarji, Catherine the Great forced Turkey to recognize the Crimea as independent and in 1783 she annexed the peninsula. There in the Crimean War (q.v.) of 1854–56 the Anglo-French armies fought the Battle of the Alma, Inkerman, and Balaklava (qq.v.) and laid siege to Sevastopol. Sevastopol was once more to make a prolonged and desperate defense against besiegers in the German invasion of 1941. In 1945 the heads of the Allied powers, Churchill, Stalin, and Roosevelt, met at Livadiya near Yalta.

**Population.**—Many of the Tatars of the Crimea were forcibly dispersed to other parts of Russia after the Crimean War, but enough remained for an autonomous republic to be set up for them in the Crimea in 1921. However, after 1945 the remaining Tatars were also dispersed, for collaboration with the Germans, and the Crimea was downgraded to an oblast of the Russian Soviet Federated Socialist Republic. It was transferred to the Ukraine in 1954. Nearly all the population is Russian and Ukrainian. Scarcely any of the Karaite Jews, who once lived there, survive.

In 1959, 65% of the population was urban. The largest of the 13 towns are the administrative centre of Simferopol (pop 186,000), the port and naval base of Sevastopol (148,000), Kerch (98,000), Yevpatoriya (57,000) (qq.v.), Yalta, and Feodosiya.

**Economy.**—The Crimea is of great agricultural importance. The northern steppes grow mostly winter wheat, maize (corn), and sunflowers. The dry climate there is marginal for agriculture and after 1961 a canal was constructed to bring irrigation water from the Dnieper at Kakhovka. In the mountain valleys and on the southern coast there are extensive and expanding vineyards. There, much good tobacco is grown, as well as roses, lavender, and sage. The number of livestock, chiefly cattle and sheep, is well above the average for Ukrainian oblasts.

Iron ore is mined on a large scale in the Kerch Peninsula. Although the ores have a low iron content (about 40%), they are close to the great industrial area of the Donets Basin. Heavy industry is largely concentrated in Kerch, with iron and steel, chemical, and engineering works. Some chemical industries are based on brine from the Sivash. Other towns have light engineering and light industries, while the processing of agricultural products is widespread (canning, wine, tobacco, and scent-making). There are many quarries of building stone, such as Balaklava limestone and Crimean diorite, which is used as a decorative stone throughout the U.S.S.R. Fishing is important.

Along the southern coast the tourist industry is well developed, the main centres being Yalta, Gurzuf, Alushta, and Alupka. A fast motor road links the resorts to Moscow. There are numerous sanatoria and rest homes. The frequently clear skies led to the

establishment at Simeiz of one of the largest observatories of the Soviet Union.

**CRIMEAN WAR**, the war of 1854-56, fought mainly in the Crimean peninsula, between Russia on the one hand and Great Britain, France and Turkey, with support from Jan. 1855 by Sardinia (Piedmont), on the other. The war arose from a series of misunderstandings and diplomatic errors in the conflict of interests of the great powers in the near east. The Straits convention of 1841 had implied that no single power was to seek exclusive influence in Ottoman affairs, but the chaotic Turkish administration caused constant concern and the spread of nationalism everywhere was likely to threaten European Turkey with the same disorders that had produced the revolutions of 1848-49 in Europe (see EASTERN QUESTION).

**The Seymour Conversations (1853).**—Disturbances in Montenegro in Dec. 1852 alarmed Nicholas I of Russia. His foreign minister, Count K. V. Nesselrode, therefore began sounding Sir Hamilton Seymour, the British ambassador to Russia, on the British attitude to the Turkish question. At the same time the earl of Aberdeen formed his government in Great Britain (Dec. 28, 1852). In his talks with Seymour (Jan. 9 and 14, 1853), Nicholas painted a gloomy picture of the Ottoman situation and said that Turkey was "very sick." However, he merely desired some prior arrangement with Great Britain to meet a possible crisis and to provide for a peaceful partition, should the Ottoman empire disintegrate. In his dispatch to Seymour of Feb. 9 the British foreign secretary, Lord John Russell, declared that he thought the possibility of a Turkish collapse remote and that in any case a two-power agreement might itself cause war; he added his assurance that Britain would in all circumstances consult Russia. Nicholas I was well satisfied by the British attitude.

**The Holy Places.**—Subsequent friction between Russia and Great Britain thus had other sources. Ostensibly the dispute arose over the question of the Holy Places in Palestine. Nicholas I, convinced that France was too much occupied with internal affairs to adopt a forward foreign policy, felt that Great Britain alone need be consulted. In France, however, the new emperor, Napoleon III, and the Bonapartist faction were in fact inclined to a policy that would at once satisfy nationalist pride, serve the

interests of French commerce in the Levant and please the clergy by the assertion of the Roman Catholic Church's priority in the Holy Places, but Nicholas thought that they would never secure the necessary British backing to pursue it.

The Holy Places consisted of the churches of the Holy Sepulchre and of the Virgin in Jerusalem, the church of the Nativity in Bethlehem and the place of Golgotha. The priests of the Latin rite had been associated in the administration of the Holy Sepulchre up to 1808, when the sultan had handed it over to the Greeks, who remained in possession despite the *firman* of 1812 restoring the Latins. The French, however, having already obtained that the keys of the church at Bethlehem and the grotto of the Holy Manger should be handed over to the Latins (Feb. 1852), extracted further concessions in Dec. 1852. Nicholas, therefore, seeing this pressure on the sultan as a threat to Russian influence in Ottoman affairs contrary to the spirit of the Straits convention, decided to make the Holy Places a test issue and sent Prince A. S. Menshikov to Turkey to clarify Russia's position and to assert Russian rights under the treaties of Kuchuk-Kainardji (1774) and Adrianople (1829). He wrongly assumed that he could assert Russian rights against France without arousing the misgivings of Great Britain. As early as March 20, 1853, Lord John Russell, then minister without portfolio (he had surrendered the foreign office to Lord Clarendon in February), said that a near eastern crisis was imminent. The news that a Russian observation corps in Bessarabia had been mobilized and the Black Sea fleet put on a war footing at Sevastopol seemed to confirm this, since both measures would intimidate the Turks. British suspicion was shown by the renewed appointment of Viscount Stratford de Redcliffe (*q.v.*) as British ambassador to Turkey. Stratford, who took up his duties in April, was well-known as a leading opponent of Russia at the Straits. His appointment led the Turks to believe that they might enjoy British support.

**The Menshikov Mission and the Outbreak of War.**—On May 5, 1853, Menshikov presented the Russian demands that Russia's treaty rights should be recognized. He even offered a secret alliance to uphold the sultan's authority. Stratford advised the Turks to be cautious, but the Porte (the Turkish government), though ready to give assurances about the Holy Places, was not disposed to flout Turkish opinion by submitting to Russia on the

THE CRIMEAN WAR 1854-56

major questions of the treaties of Kainardji and Adrianople. On May 21 Menshikov withdrew his mission, having failed to obtain a satisfactory reply. Aberdeen and the British cabinet thought that the Russian demands were unreasonable, aiming at establishing a Russian protectorate over Turkey. On June 2 the British fleet was ordered to Besika bay, just outside the Dardanelles, where it arrived on June 13, to be joined by a French squadron next day. Nicholas I, determined to uphold Russia's position, on June 27 ordered the occupation of the principalities of Moldavia and Walachia, and the Russian forces crossed the Prut on July 4.

To prevent hostilities, British, French, Austrian and Prussian representatives conferred in Vienna during July, and on Aug. 1 recommended in their "Vienna note" that the sultan should "remain faithful to the letter and spirit of the treaties of Kainardji and Adrianople relative to the protection of the Christian religion," not altering them without French and Russian consent. The Russian attitude was that the Vienna note was merely a confirmation of existing treaty rights, but the Porte, in spite of Stratford's recommendation of Aug. 12 to accept the note, declared on Aug. 19 that the Turkish government itself would undertake the protection of the Christian religion. The Turkish declaration meant the exclusion of all foreign intervention, whereas Russia was claiming the right to intervene.

The deadlock produced a sense of panic in London, especially when the French ambassador informed Clarendon that there was a danger of rioting in Constantinople and on Aug. 23 Aberdeen and Clarendon, without cabinet authority, issued the order for the British fleet to move up to Constantinople. At a meeting with the Austrian emperor Francis Joseph on Sept. 24 Nicholas I expressed willingness to accept the face-saving formula that recognition should be given to the rights of Russia under the treaties of Kainardji and Adrianople and to the sultan's duty to protect the Christian religion, but this was unacceptable to the British government. The Turks had by now sensed that they could provoke a crisis and in the long run obtain British and French support. On Oct. 4 Turkey declared war on Russia, though Stratford refused to put into operation the cabinet order which he received that day to call up the fleet to Constantinople, for fear of encouraging Turkish intransigence. The British order to the fleet was nevertheless repeated on Oct. 8. On Oct. 20 Austria, Prussia, Great Britain and France made representations to the Porte to avoid hostilities, but on Oct. 23 Omer Pasha opened the attack upon Russian troops in the principalities and on Nov. 1 Russia declared war on Turkey. The British and French fleets were then called into the Bosphorus. The Russians could not be expected to remain idle while the Turks attacked them. Accordingly on Nov. 30 the Russian Black Sea fleet under Admiral P. S. Nakhimov destroyed a Turkish squadron off Sinop, to prevent its giving aid to the Ottoman forces on the Caucasian front. This Russian naval victory excited great indignation, especially in Great Britain.

Aberdeen wavered in the face of public demand for resolute action. On Dec. 22 he agreed to co-operate with France to the extent of sending the two fleets into the Black sea to contain the Russian fleet at its base at Sevastopol. The fleets entered the Black sea on Jan. 3, 1854, offering a direct challenge to Nicholas I; he therefore withdrew his ambassadors from London and Paris in February. On Feb. 27 Great Britain and France delivered an ultimatum: that Russia should evacuate the principalities of Moldavia and Walachia—a demand which seemed to show desire to associate Austria with their action, for Austria was vitally interested in that area. On March 12, 1854, Great Britain and France concluded a military alliance with Turkey. As Russia made no reply, they declared war on March 27.

**The War to the Battle of Inkerman.**—The allies first sought to isolate Russia diplomatically. On April 9, 1854, Austria, Prussia, Great Britain and France signed an agreement to maintain the *status quo* in Turkey and the principalities. On April 20 Austria and Prussia signed a treaty of armed neutrality, by which Prussia undertook to assist Austria in case of a Russian attack—an unlikely event, because Nicholas I would wish to avoid trouble. On April 29 British and French troops disembarked at Varna to protect Constantinople from attack by the Russian army. The

way was therefore clear for Austrian action, and on June 3 Austria demanded that Russia should evacuate the principalities. Threatened with an Austrian attack, Russia on Aug. 5 ordered its army to withdraw from Moldavia and Walachia, permitting the Austrians, by agreement with Turkey as the suzerain power, to enter them and thus seal off the Balkan theatre of war. The Russian move was astute because it also satisfied the terms of the Franco-British ultimatum of Feb. 27. Austria was therefore less inclined to support British and French action, while the allies were left with no obvious reason for fighting. They nevertheless needed to achieve some solid success to satisfy public opinion. Unable to attack in the principalities, they decided to send an expedition to the Crimea to destroy the naval base at Sevastopol.

On June 29, 1854, the British cabinet ordered its forces to invade the Crimea and the allied commanders, Lord Raglan and Gen. A. J. Leroy de Saint-Arnaud, met at a war conference at Varna on July 18. On Sept. 14 an allied force was landed at the port of Eupatoria, but neither Raglan nor Saint-Arnaud was a vigorous commander; both were in fact to die during the course of the war. Saint-Arnaud in Sept. 1854 (to be succeeded by Gen. F. C. Canrobert), and Raglan in June 1855 (to be succeeded by Gen. Sir James Simpson). Both allied armies had on the whole elderly officers and used outdated methods. The Russian forces under Menshikov showed equal lack of tactical skill: they let the allies land unopposed. The allies advanced south against Sevastopol, but in the confused and costly battle of the Alma (*q.v.*) on Sept. 20 they failed to exploit their advantage and could not take the north and weaker side of the fortress. They therefore decided to march to the southern side of the city, where they could be more easily supplied by sea. The bombardment of Sevastopol was begun on Oct. 17, but the French magazine blew up and the final assault had to be postponed. Delays gave the city a chance to prepare its defenses. The ensuing engagements were marked by scant military skill. A Russian counterattack at Balaklava on Oct. 25 was repulsed with considerable losses on both sides. (*See BALAKLAVA BATTLE OF*.) A second Russian attack on Nov. 5 at Inkerman (*see INKERMAN, BATTLE OF*) was so costly to the allies that they abandoned an assault on Sevastopol and would be obliged to winter in the Crimea. On Nov. 14 the British supply ships were destroyed in a violent storm. This left the British army in a lamentable state when winter set in.

The British public, kept in touch with the details of military operations by telegraphic reports printed in the newspapers, bitterly criticized Aberdeen's government for mismanaging the campaign. The mission of Florence Nightingale (*q.v.*) with a party of female nurses to tend the sick and wounded at Scutari (Çeskidar on the Bosphorus) gave additional publicity to the British army's sufferings. Some glorious success was now most urgently required if the government was not to be defeated in parliament. Napoleon III and his advisers felt similar anxieties. The British and French governments therefore redoubled their efforts to bring Austria into their alliance in order to ensure military victory.

**Diplomatic Efforts to End the War.**—When Austria demanded that Russia evacuate the principalities on June 3, 1854, the Austrian foreign minister, Count K. F. von Buol-Schauenstein, foresaw the dangers of war and therefore asked the allies to declare their war aims. Discussions then led to the notes of Aug. 8, 1854, which stipulated these four points: (1) a European instead of a Russian guarantee for the principalities; (2) the improvement of Danubian navigation; (3) the revision of the Straits convention of 1841 "in the interests of the balance of power"; and (4) the substitution of a European protection for the Christian subjects of the Ottoman empire in place of Russian protection.

The Austrian government was in doubt whether or not to make an alliance with Great Britain and France, but false rumours that Sevastopol had fallen (which would have allowed the allies to withdraw honourably from war) prompted Buol to submit a draft treaty. On Dec. 2 a formal treaty of defensive alliance was signed between Austria, France and Great Britain but with the proviso that, if Russia rejected the four points, the powers should concert measures to make their alliance effective, which meant that Austria would declare war on Russia. Buol, however, had received news

BY COURTESY OF THE GERNSHEIM COLLECTION, UNIVERSITY OF TEXAS

BALAKLAVA, WHERE A MAJOR ENGAGEMENT OF THE CRIMEAN WAR WAS FOUGHT IN 1854

motion was unanswerable. After defeat in the house of commons, Aberdeen's government itself resigned on Jan. 29. Lord Palmerston formed an administration in February on the understanding that steps would be taken to end the war but, when the pacific Peelites members of his cabinet resigned because he would not resist an inquiry into the management of the war, he reverted to a more warlike policy. Meanwhile Lord John Russell had been sent to Vienna to act as British plenipotentiary, under the impression that Britain's intent was pacific. Peace was in the air, for on March 2, 1855, Nicholas I had died; with the accession of Alexander II the emperor's personal prestige no longer seemed a factor.

When discussions opened in Vienna on March 15 the interpretation of point 3 still gave trouble. Buol and Lord John Russell began to move a compromise

on Nov. 20 that Nicholas I would accept the four points, so that war between Austria and Russia seemed in part unlikely.

The key to the situation was the third of the four points, the revision of the Straits convention. For internal political reasons, Great Britain and France interpreted this to mean the destruction of the naval base at Sevastopol and the removal of the Russian fleet from the Black sea. This would have justified the war costs and the heavy loss of life, but was a demand so far reaching that Austria was unlikely to force it on Russia. Great Britain and France therefore resorted to a subterfuge in their exchange of notes with Austria of Dec. 17-19. In their notes to Austria they defined point 3 as meaning to end "the preponderance of Russia upon the Black sea," which was vague; but between themselves they agreed that "England and France must insist upon the demolition of Sevastopol." On Dec. 28 the British and French ambassadors (the earl of Westmorland and Baron F. A. de Bourqueney) in Vienna and Buol agreed to meet Prince A. M. Gorchakov, the Russian ambassador, and asked him if he would negotiate on the four points as defined in the British and French notes to Austria. Gorchakov inquired whether this meant the destruction of Russian fortresses, to which the ambassadors replied that they could not discuss the four points, but asked merely whether negotiations were possible. When Gorchakov stated that he would consult his government and asked for 15 days' grace, the ambassadors thought that he was merely seeking to postpone a rupture with Austria and that Russia would eventually refuse to negotiate with the result that Austria would enter into the war on their side. Gorchakov, however, outmaneuvered them. He wrote to Buol asking that the powers should seek to impose "no condition which might detract from the tsar's sovereign rights," which Francis Joseph agreed was a good basis for negotiation. The French ambassador objected strongly to this formula, but Buol neither wanted war, nor wished to oppose his emperor's opinion: Gorchakov saw his chance to exploit a fundamental difference between Austrian and allied policies. On Jan. 2, 1855, Francis Joseph assured him he had no intention of offending the tsar's dignity. Gorchakov thus found that Russia could negotiate on more equal terms with the allies, and secured his government's approval to open discussions. This was agreed by the ambassadors in Vienna on Jan. 7. The allies had trapped themselves into negotiating on terms other than the destruction of Sevastopol.

A ministerial crisis in London further complicated the situation. On Jan. 23, 1855, J. A. Roebuck tabled his famous motion for an inquiry into the condition of the British army before Sevastopol. Lord John Russell resigned on the grounds that the

solution limiting the number of Russian ships on the Black sea, but on March 30 the French foreign minister, Edouard Drouyn de Lhuys, visited London, where he and Palmerston formulated schemes of limitation and neutralization which they considered would be unacceptable to Russia and therefore force Austria into the war. Drouyn arrived in Vienna on April 6, but Buol would have nothing to do with the London plans and began to put forward a plan of his own for limitation or a "counterpoise," by which he meant a British and French guarantee to Austria. Drouyn had consistently worked for a permanent French alliance with Austria, which he considered would force a more conservative policy on the unreliable Napoleon III. He therefore returned to Paris to press Buol's plan on Napoleon. In view of the disarray of the allies, Gorchakov announced on April 17 that he could not accept the principle of limitation, and the conference was adjourned *sine die* on April 21.

At first Napoleon III was inclined to accept the Austrian plan but Lord Cowley, the British ambassador, was against it and Marshal J. B. P. Vaillant, the minister of war, declared that the French army's honour now required a military victory. Napoleon therefore rejected Drouyn's advice. Drouyn resigned and was replaced by Alexandre Walewski. Lord John Russell, at first inclined to offensive action, had at Vienna come to favour peace. When this reversal became publicly known, he was attacked in the commons and resigned on July 13, never again able to challenge Palmerston's leadership for the Liberal party.

**The Continuation of the War.**—The war dragged on into the spring and summer of 1855. The allied forces, joined by 15,000 Sardinians on Jan. 26, began a series of costly bombardments and assaults on Sevastopol. Marshal J. J. Pélissier, who succeeded Canrobert on May 16, successfully raided Kerch on May 24, and allied ships ravaged the shores of the Sea of Azov. In the Baltic an allied squadron subjected Sveaborg (Suomenlinna) to a 45-hour bombardment. On Aug. 16 a Russian counterattack under the new Russian commander-in-chief, Gen. Mikhail Dmitrievich Gorchakov, was repulsed on the Chernaya. On Sept. 8, Gorchakov gave the order to evacuate Sevastopol, but the British and French forces were too weak to pursue the Russian troops.

With Sevastopol captured, Napoleon III was satisfied and willing to negotiate, but Russia was not easily persuaded. The allies thus sought to exert further pressure, even proposing to raise the Polish question, but the year was too far gone for new operations. The only further allied action was to bombard and destroy the Russian base at Kinburn. Buol, however, thought that Austria had now so much offended Russia as to have forfeited the diplo-

GERNSHEIM COLLECTION

ENCAMPMENT OF HORSE ARTILLERY IN THE CRIMEA, 1855

matic support in central Europe which Russia had given Austria in Metternich's time and Austrian policy must rest henceforth instead on an alliance with Great Britain and France. On Nov. 14, therefore, he agreed with Bourqueney on the presentation of an Austrian ultimatum to Russia, which would include the demand for the neutralization of the Black sea. This proposal was finally agreed on Dec. 5, and on Dec. 16 Valentin Esterhazy was sent to St. Petersburg with an ultimatum, which he delivered on Dec. 28. Meanwhile Russia learned of a Franco-British defensive alliance with Sweden, which might spread war to the Baltic. The Russian ministerial council on Jan. 1, 1856, considered a plan for submitting counterproposals to Austria, but both Esterhazy and Buol warned Russia that this would be construed as a refusal of the ultimatum. On Jan. 15 the council advised Alexander II that Russia must submit, and accordingly the Austrian ultimatum was accepted. Russian statesmen saw that prolonged resistance, though possible, would lead only to further reverses whereas Russia would not be without advantages at the peace conference. The allies had not gone far into Russia, while in Asia Minor the Russians had captured Kars on Nov. 27, 1855, which gave Russia some bargaining power. Moreover, there were signs that Napoleon III was contemplating links of friendship with Russia and would not always support British and Austrian demands. The policy of Russia was therefore to submit when the three powers were united and to exploit their differences when they disagreed.

The Crimean War had important consequences. Alexander II realized that the defeat of Russia was due to the empire's backwardness and that social conditions must therefore be attuned to those prevailing elsewhere in Europe. They saw also that during the long period of modernization Russia would be unable to exert so much influence abroad as between 1815 and 1848. This new passivity of Russia greatly altered the pattern of European diplomacy. Austria, by submitting the ultimatum of Dec. 1855, had sacrificed Russian diplomatic support, but did not secure the expected territorial guarantee from Great Britain and France. The Crimean War above all isolated Austria diplomatically after 1856 and thus began the events which brought about the defeats in 1859 and 1866, which in their turn led to the unification of Italy and Germany.

For the treaty of Paris (1856) and its effects see **EASTERN QUESTION**. See also references under "Crimean War" in the Index.

(R. F. LE.)

**CRIMINAL APPEAL, COURT OF.** The English Court of Criminal Appeal was created by statute in 1907. Its membership includes the lord chief justice and all judges of the Queen's Bench Division of the High Court of Justice. Its primary function is to review judgments in criminal cases (see **COURT, ENGLISH**).

Prior to 1907, there was no right of appeal in important criminal cases in England and Wales. A practice had developed much earlier of reserving questions of law arising at criminal trials for resolution by all trial judges. The procedure was formalized by statute

in 1848 with the creation of the court for crown cases reserved. But review by this method was entirely at the discretion of the trial judge or the chairman of the quarter sessions. Beginning in 1844, efforts were made in Parliament for legislation which would mirror that adopted by most Western countries. Much of the agitation that forced the bill through the House of Commons was the result of the conviction of Adolph Beck in 1904 on what was ultimately shown to be a case of mistaken identity. Ironically, the error in the Beck case is not one subject to correction by the appellate process, since the function of determining the credibility of witnesses, except in extraordinary circumstances, is one that is still allocated to the trier of the facts.

Unlike the Court of Appeal (*q.v.*), which hears appeals in civil cases in England and Wales and which is staffed largely by judges hearing nothing but appellate cases, the Court of Criminal Appeal ordinarily consists of two trial judges and the lord chief justice as presiding officer. The statute as amended, however, authorizes any odd number of judges of the Queen's Bench Division to act as the Court of Criminal Appeal, and a bench of five has occasionally been invoked where special circumstances have warranted. Indeed, on one occasion the court was made up of 13 judges.

The court's powers are broad. An appeal of right may be taken on any question of law. With leave of the trial judge or the Court of Criminal Appeal, issues of fact may also be reviewed. Also, with leave of the Court of Criminal Appeal, it may entertain an appeal from sentence. The court may dismiss the appeal, quash the conviction, or modify the sentence, either by increasing or decreasing it. But as in most Anglo-American systems, there can be no appeal from a judgment of acquittal. Unlike the rule in most other jurisdictions, however, the Court of Criminal Appeal has no power to order a new trial. An amendment to accomplish this result was rejected by parliamentary committee in 1948, but it continues to be a subject of controversy.

The Court of Criminal Appeal deals with about 1,500 cases each year. All applications for leave to appeal are sent to a single judge. If he denies leave, the defendant has the right to seek review by a full court. If any member of the full court thinks leave should be granted, the appeal is heard. When the full court sits, it hears appeals first and then passes on applications. Decisions are given by the judges in rotation but all judges read all papers presented for consideration. Leave to appeal is granted in about 5% of the cases involving alleged error in conviction and in about 6½% of the cases where sentence is contested. Appeals are heard on the basis of transcripts of the trial proceedings, or relevant portions, and oral argument by counsel. The court, however, has the power to take additional evidence.

Judgments may be reviewed in the House of Lords, but only when a law officer has certified that a point of law of exceptional public importance is involved. Since such certificates are given on the average of once a year, for all practical purposes the Court of Criminal Appeal is a court of last resort.

See also **APPEAL**; *Great Britain and the Commonwealth*.

See H. Cohen, *The Criminal Appeal Act, 1907* (1908); Lord Goddard "The Working of the Court of Criminal Appeal," *Journal of the Society of Public Teachers of Law*, vol. ii, n.s., p. 1 (1952). (P. B. K.)

**CRIMINAL LAW** may be broadly conceived as that body of law which defines criminal offenses, establishes procedures for the apprehension, charging, and trial of suspected offenders and which fixes penalties and modes of treatment applicable to convicted offenders. All organized societies display, even if in rudimentary form, a body of rules, norms or customs tending to protect the security of individual interests and the survival of the group as a whole. The distinction between the criminal law and other forms of social control, however, is ordinarily not sharply drawn in primitive societies. Even in modern Anglo-American law the distinction between criminal law and tort law defies wholly satisfactory definition. For most practical purposes, however, it is sufficient to say that a tort is a private injury and that the purpose of a tort suit is primarily to obtain compensation from the wrongdoer for injuries sustained by the victim. A crime, on the other hand, even though it may (and ordinarily does) involve injury to some individual, is conceived as an offense against the state

and is punishable as such. Thus the same conduct may render the actor liable in tort to make compensation to the victim for injuries inflicted and, at the same time, answerable to the state in a criminal proceeding. Tort law and criminal law may also be distinguished by the procedures employed and the sanctions imposed in the two types of actions. (See also TORT.)

## I. SOURCES OF THE CRIMINAL LAW

**1. England.**—The modern criminal law of England and of the United States derives from the English common law of crimes. This body of law had its origins in judicial decisions which, by the middle of the 13th century, were applied throughout the realm and were thus "common" to it. Even in the medieval period, however, legislation played an important role in the development of the English law of crimes. In some instances legislation was confined to matters of procedure or the stipulation of penalties, leaving definition of the elements of the offenses to judicial precedents. Thus, as late as the 1960s there was no statutory definition of murder in English law. Even the Homicide act, 1957, confined itself to such matters as eliminating certain types of conduct from earlier judicial definitions of murder and specifying the types of murder punishable by death. In other instances, however, parliament has created offenses wholly unknown to the common law. Examples include the embezzlement acts of the 18th century and the spate of statutory offenses enacted in increasing numbers since the first quarter of the 19th century to achieve objectives of economic regulation or public welfare. England has consistently rejected all efforts toward comprehensive legislative codification of its criminal law, even though the movement for codification has been supported by the prestige of such names as Jeremy Bentham and Sir James F. Stephen. (See also ENGLISH LAW.)

**2. United States.**—Although the criminal law of the United States clearly reveals its derivation from the English common law, the adoption of the common law was neither complete nor uniform in the American colonies. The early criminal legislation of Massachusetts, for example, was little influenced by English precedents, being derived in major part from Old Testament sources. In New York the influence of English precedents was earlier and more strongly felt. The famous "Quaker code" brought by William Penn to Pennsylvania and Delaware in the closing years of the 17th century was remarkable for its leniency in that only one capital offense, murder, was recognized. Although Penn's code was operative for only a short period, it is important as anticipating by over a century the humanitarian impulses later reflected in the Anglo-American law. Throughout the 18th century an increasing number of lawyers trained in the English law practiced in the colonies, and their influence strongly supported recognition of common-law principles by colonial courts and legislatures. By the time Sir William Blackstone's *Commentaries* were published (1765–69), the common law of crimes was generally adopted. After the American Revolution, the states incorporated into their law the English common law as it existed prior to a specified date (either 1607, when the settlement at Jamestown was founded, or 1776, the date of the Declaration of Independence). The adoption of the common law was made subject to the constitution of the United States and of the particular state and only insofar as compatible with the conditions of the new nation. These limitations encouraged the rejection of certain archaic features of the common law of crimes, particularly those relating to outmoded and degrading forms of punishment.

In about one-third of the states of the U.S. the common law of crimes has been expressly repealed by legislation. The effect of such enactments is primarily that no person may be tried for an offense not specified in the statutory law of the state. Common-law principles retain great influence in such jurisdictions, however, for the criminal statutes often are simply codifications of the common law, and their terms and provisions are ordinarily interpreted by reference to the common law. No federal offenses other than those provided for by statute are recognized, but, again, federal criminal statutes are interpreted in the light of the common law. In the remaining states, prosecutions for common-law offenses not specified in the statutes are possible and sometimes

occur. Among the most numerous of these prosecutions are those for conspiracy, criminal solicitation and breach of peace.

Criminal legislation has proliferated in the United States, as in England, since the first quarter of the 19th century. It has been estimated that the number of offenses defined by U.S. legislatures doubled in the first half of the 20th century. This frequent resort to penal legislation, however, has ordinarily not been accompanied by sober and systematic consideration of the issues of penal regulation by U.S. lawmakers. In many states the so-called penal or criminal codes are simply collections of individual provisions enacted at different times in response to particular problems then current, with little effort to relate the parts to the whole or to define or implement any general theory of social control by penal measures. As a result, U.S. criminal legislation characteristically is poorly drafted, inconsistent and ill-considered. Nor have the courts succeeded conspicuously in rationalizing the U.S. criminal law through the processes of judicial interpretation. Early in the 19th century, U.S. disciples of Jeremy Bentham, such as Edward Livingston, advocated comprehensive and systematic codification of criminal legislation. While these efforts were not wholly devoid of results, they did little to affect the character of U.S. criminal law as a whole. In the 20th century three states adopted comprehensive criminal codes: Louisiana in 1942, Wisconsin in 1956 and Illinois in 1961. Since World War II greater and more serious interest in the criminal law has been manifested in several U.S. jurisdictions. At the beginning of the 1960s a number of states, including New York, Minnesota and Missouri, were considering fundamental revisions of their criminal statutes. Such interest has been significantly stimulated by the American Law institute, a private organization of lawyers and judges, which in 1952 began the drafting of a model penal code. The model code represents the co-operative efforts of judges, lawyers, legal scholars and behavioural scientists. In 1930 the American Law institute published a model code of criminal procedure. The adoption of the Federal Rules of Criminal Procedure in 1946 also provided a stimulus for procedural reform in other U.S. jurisdictions.

**3. Continental Countries.**—The nations of western Europe entered the modern period with a corpus of criminal jurisprudence reflecting the varying influences of Roman law, canon law and local custom. The law that so evolved was notable for its harshness and its arbitrary qualities, and few protections to accused persons were provided. Reform of the criminal law thus became an important objective of liberal reform. As early as 1532 Charles V promulgated the *Constitutio Criminalis Carolina* for the whole of the Holy Roman empire. Austria produced two famous codes in the 18th century: the *Constitutio Criminalis Theresiana* of 1769 and the emperor Joseph II's code of 1787.

By far the most important enactments in the history of modern European criminal law were the two Napoleonic codes, the code of criminal procedure of 1808 (*Code d'Instruction Criminelle*) and the *Code Pénal* of 1810. The first was finally replaced in 1958 by the *Code de Procédure Criminelle*, but the latter, although substantially revised in 1832 and in 1863 and frequently amended at other times, has never been repealed. The *Code Pénal* constituted the leading model for European criminal legislation throughout the first half of the 19th century. Thereafter its influence waned, although it continued to play an important role in the legislation of certain Latin American and middle eastern countries. The German codes of 1871 (penal code) and 1879 (procedure) provided the models for many central European countries. The German influence has also been significant in Japan and South Korea. The Italian codes of 1930 represent one of the most interesting legislative efforts in the modern period. Since World War II notable undertakings include the code of procedure of 1950 and the penal code of 1957 adopted by the German Federal Republic and the Yugoslav criminal code of 1951. (See also FRENCH LAW; GERMAN LAW.)

## II. SUBSTANTIVE CRIMINAL LAW

The substantive criminal law is concerned with defining the kinds of conduct that are to be considered criminal, thereby render-

ing the perpetrators eligible for penal sanctions. "Conduct," as the word is used in this context, should be understood as encompassing not only specified acts or omissions but the accompanying mental states as well. The substantive law consists of more than provisions of statutes or judicial decisions articulating the ingredients of particular offenses. Attention must also be given to certain doctrines, some of them of constitutional origin, which exclude various kinds of conduct from the definition of criminal behaviour, and to certain principles which apply to all or large parts of the substantive law and which qualify the provisions of criminal legislation even though not expressed in the particular statute defining the offense.

#### A. LIMITATIONS ON THE DEFINITION OF CRIMINAL CONDUCT

**1. Constitutional Limitations.**—The criminal law, having at its disposal some of the most rigorous sanctions within the power of the state, inevitably poses fundamental problems regarding the relations of the individual and the political group. It is not surprising, therefore, that the regulation of the criminal process is one of the primary objectives of U.S. constitutional law. Most of the constitutional limitations apply to matters of criminal procedure, but others directly limit the power of legislatures and courts to denounce certain types of behaviour as criminal.

At the outset, no political entity may denounce and punish behaviour that falls outside its jurisdiction. Thus the federal government, being a government of delegated powers, may declare criminal only behaviour that falls within the scope of its granted authority. The validity of a federal criminal statute must be predicated on such bases of authority as the power of congress to regulate foreign and interstate commerce, the revenue powers, the war powers, powers relating to the currency, and the like. The individual states are also presumably limited to punishment of behaviour occurring within their geographical boundaries or, if it occurred elsewhere, to conduct affecting the interests of the state in some substantial way.

The constitutional grant of freedom of speech or religion has as its natural consequence the immunization of conduct falling within these provisions from criminal punishment by federal or state authority. Thus, in *Cantwell v. Connecticut*, 310 U.S. 296 (1940), the U.S. supreme court overturned a state conviction for the common-law crime of breach of peace upon a finding that the conduct of the defendant was within the exercise of his freedom of religion protected by the 14th amendment of the U.S. constitution. In the U.S. political system the states enjoy broad powers of regulation, including regulation by criminal sanctions, in the interests of public health, safety and morals. Occasionally, however, attempts at such "police power" regulation have been held to exceed the limits of constitutional tolerance. Thus a New York statute that imposed criminal sanctions on junk dealers having stolen goods in their possession, even when the dealer did not know and could not reasonably have discovered the goods were stolen, was held to be unconstitutionally arbitrary and a violation of due process of law (*People v. Estreich*, 272 App. Div. 698 [1947]). State criminal legislation may be voided when the state has attempted to enter a field validly regulated by the federal government and the state statute is deemed incompatible with the proper exertion of federal power. The equal-protection clause of the 14th amendment forbids the enactment of criminal legislation which discriminates on grounds of race or colour or which erects other unreasonable classifications. Various other constitutional provisions may limit legislative powers in the definition of criminal offenses. (See also CONSTITUTION AND CONSTITUTIONAL LAW: United States.)

**2. Legality.**—The first article of the U.S. constitution (sec. 9, cl. 3 and sec. 10, cl. 1) and the constitutions of most of the states contain provisions prohibiting the enactment of ex post facto legislation. These provisions represent an expression in constitutional form of one aspect of the broad principle of legality or the rule of law in the criminal process, recognized as fundamental in most civilized legal systems.

The principle of legality has been employed in four senses. The most common usage is that there can be no crime without a

criminal law. Conduct may be immoral or antisocial, but it is not criminal without a law which forbids it. This application of the principle parallels the maxim of the European criminal law, *nullum crimen sine lege* ("no crime without law"), which was abandoned in 1926 when the Soviet code penalized any "socially dangerous" behaviour and by Germany in 1935 when conduct was made punishable even though not forbidden by statute if it violated "the sound feelings of the people."

Second, the principle directs that only legally prescribed punishment can be imposed upon a convicted person. This is reflected in the maxim of the European law, *nulla poena sine lege* ("no punishment without law"). In the United States it has been held that the principle is not violated by statutes providing indeterminate sentences so long as the maximum limits are specified.

Third, the principle of legality forbids retroactive penal legislation. In order that a person may be convicted, a law must have been in effect at the time of the conduct, forbidding it and rendering it punishable. It is to this aspect of the principle that the ex post facto provisions of the U.S. constitution directly relate. (See also EX POST FACTO LAW.)

Fourth, the principle of legality requires that criminal statutes be interpreted strictly; i.e., ambiguities and vagueness must be resolved in favour of the accused. In the United States most of the litigation involving the principle concerns this application of it. If a criminal statute is vague, it is unconstitutional as violative of due process (*Lansetta v. New Jersey*, 306 U.S. 451 [1939], declaring invalid a statute which penalized membership in a "gang"). If a criminal statute is ambiguous it is not invalid, but it is given a narrow interpretation favourable to the accused. Thus in *McBoyle v. U.S.*, 283 U.S. 25 (1931), it was held that an airplane is not included in a federal statute which penalized stealing any "motor vehicle . . . or any other self-propelled vehicle for running on rails." The rule of strict construction is not properly employed, however, to defeat the clear purposes of the legislature. Occasionally U.S. state legislatures, in reaction to the rule, have enacted provisions similar to that of New York: "The rule that a penal statute is to be strictly construed does not apply . . . but all such provisions must be construed according to the fair import of their terms, to promote justice and effect the objects of the law" (N.Y. Penal law, sec. 21).

All the applications of the principle of legality are intended to assure that no person will be punished as a criminal except on the basis of definite law existing at the time the act in question was committed. The major attack on the principle has been made by some criminologists and psychiatrists who contend that the fixing of maximum sentences handicaps rehabilitation of the criminal and defense of social interests. By the early 1960s this position had not found acceptance in the legislation of any state; everywhere maximum limits were prescribed by statute. Since World War II it has become widely and increasingly accepted that, although considerable discretion should be allowed for individualization of treatment of offenders, that power in a democratic community must be subjected to reasonable restraints.

**3. Entrapment.**—In the United States the scope of criminal liability is limited by the doctrine of entrapment. When acts otherwise criminal are committed by the accused as a result of the direct instigation of law-enforcement officers or undercover agents, criminal liability does not attach. Entrapment should be distinguished from situations in which the officer does not instigate the offense but merely provides the opportunity or occasion for its commission. The distinction in many cases is a difficult one to draw. The doctrine of entrapment has received its most frequent application in cases of offenses like liquor violations, gambling and narcotic offenses. Its application to cases of homicide and those involving serious bodily injury is far from clear. Dispute has also arisen regarding the precise theoretical basis for the doctrine. By far the majority of courts take the view that an accused led into conduct otherwise criminal by the instigation of law-enforcement agents has committed no offense. Some authorities have urged that under such circumstances an offense has been committed but that the state should withhold penal sanctions from the offender. However articulated, the doctrine reflects

ethical repugnance to such law-enforcement measures.

## B. THE GENERAL PART

The substantive criminal law expresses a large number of general doctrines and principles which form an important part of the definition of criminal behaviour, even though they customarily are not expressed in statutes defining particular offenses. In a fully articulated penal code these matters are dealt with in the "general part" of the code. Of all the problems of the criminal law, those of the general part are among the most important and difficult.

**1. Criminal Act or Omission.**—It is generally agreed that an essential ingredient of any crime is a voluntary act or omission. The act may be understood as a willed muscular contraction. Its voluntary character is requisite. "The reason for requiring an act," wrote the late Justice Oliver Wendell Holmes, "is, that an act implies a choice, and that it is felt to be impolitic and unjust to make a man answerable for harm unless he might have chosen otherwise." Thus movements made in an epileptic seizure are not acts. So also, movements made by a somnambulist before awakening, even those resulting in the death of another, are not acts and do not render the sleepwalker criminally liable. The line between such cases and those involving the doctrines of insanity is sometimes difficult to draw. In general it can be said that movements performed in a state of "open-eyed consciousness" are acts, even though the acts are the product of mental disorder. In such cases exculpation must come, if at all, by virtue of the insanity defense.

Criminal liability may also be predicated on a failure to act when the accused was under a legal duty to act and was reasonably capable of acting. The legal duty to act may be imposed directly by statute, such as the requirement that those earning income must file a tax return. It may arise out of the relationship of the parties. Thus duties of care attach to the relationship of parent and child, husband and wife, guardian and ward. In the English case *Rex v. Gibbons and Proctor*, 13 Cr. App. R. 134 (1918), two persons having a child under their care were convicted of murder when the child died from the failure of the defendants to supply her with food sufficient to sustain life. Nevertheless, the duty to act is defined rather narrowly in the Anglo-American law. There is thus no general obligation to protect others from harm. These restrictions on the principle have often been protested. The proposed code for Louisiana, drafted by Edward Livingston in 1833, would have imposed liability for criminal homicide on persons failing to save the life of another when this could be achieved "without personal danger, or pecuniary loss." Proposals for the drastic enlargement of the legal duty to act are attended by genuine difficulties of articulation and administration and have generally been rejected.

**2. Mens Rea or Mental Element.**—In general, the definition of an offense includes not only an act or omission and its consequences but also the accompanying mental state of the actor. Appraisal of the moral character or social dangerousness of the offender requires that it be known whether his conduct was purposeful, reckless, negligent or accidental. Frequently, in the modern era, the Anglo-American criminal law has imposed liability without requiring the showing of a *mens rea* or guilty mind. Nevertheless, the tradition of the common law strongly supports the proposition that the stigma of serious criminality ought not, on grounds of justice and utility, to be imposed on one who produced harm inadvertently or accidentally. "Even a dog," wrote the late Justice Holmes, "distinguishes between being stumbled over and being kicked."

Despite the evident importance of proper definition of the mental element, the performance of courts and legislatures in this area has often been far from satisfactory. Criminal statutes are frequently silent on what sort of *mens rea*, if any, must be shown. In other instances, as many as two dozen different terms intended to signify various mental states are employed without clear indication of how such terms are to be interpreted and applied. In still other instances the same term is used in several statutes, although entirely different meanings are intended to be conveyed. Thus

in the U.S. cases almost every possible meaning has been attributed to the term "willfully," and almost as wide a range of meanings has been given to the word "intentionally." The tentative draft of the American Law Institute's model penal code would reduce the *mens rea* terms to four: "purposely," meaning an actual, consciously formed intent to achieve the criminal consequence; "knowingly," conscious awareness that the actor's conduct will produce the consequence; "recklessly," conscious disregard that the actor's conduct is creating an unreasonable peril; and "negligently," inadvertence to peril that would have been apparent to a reasonable man. These terms, singly or in combination, appear adequate to deal with most of the common *mens rea* problems. Their general adoption would greatly clarify and rationalize the substantive law of crimes.

**3. Absolute Liability.**—Although Sir William Blackstone, writing in the 18th century, asserted that the *mens rea* is an indispensable element of a crime, developments that have occurred largely since that time have created a considerable body of penal offenses in which no intent or other mental state need be shown. Absence of the *mens rea* requirement characterizes a few offenses like statutory rape, in which knowledge that the girl is below the age of consent is not necessary to liability, and bigamy, which in most jurisdictions may be committed even though the parties believe in complete good faith that they are free to marry. For the most part, however, absolute liability has been created by statutes defining offenses to which only slight or moderate penalties are attached. These offenses, sometimes called "public-welfare offenses," are most frequently concerned with economic regulation or with protection of the public health and safety.

The justification for elimination of the *mens rea* requirement is ordinarily made on grounds of expediency. It is asserted, for example, that to require the prosecution to establish the defendant's intent, or even recklessness, would render such regulatory legislation largely ineffective and unenforceable. Nevertheless, commentators both in England and the United States have frequently condemned the creation of absolute liability. To expose the citizen to the social moral condemnation of a criminal conviction without a showing of moral culpability raises issues of justice; and it may be doubted whether recognition of criminal guilt without moral fault serves the larger interests of the criminal law. In many instances, moreover, the regulatory objectives of such legislation can more effectively be achieved by civil sanctions such as suits for damages, injunctions and the revocation of licences. Even when criminal sanctions must be employed, it is often feasible to permit the defendant to answer the charge by showing that his conduct did not involve a negligent failure to exercise due care. Negligence, involving merely inadvertence rather than conscious wrongdoing, hardly satisfies the full requirements of the *mens rea* principle. Negligence, however, has been recognized as the basis of liability in certain statutory offenses and, in any event, is preferable to the rigours of absolute liability. By mid-20th century, courts in England and the U.S. were displaying increasing hostility to absolute criminal liability and were frequently refusing to construe statutes as creating it when a fair question of interpretation was posed. Thus, the U.S. supreme court held that a federal theft statute required proof of an intent to steal even in the absence of words of *mens rea* in the statutory language (*Morrisette v. U.S.*, 342 U.S. 246 [1952]). A number of U.S. state cases held that statutes creating absolute criminal liability denied due process of law when serious penalties were attached. The U.S. supreme court invalidated a California ordinance that punished the failure of an ex-convict to register with the police department even when the accused was unaware of the registration requirement (*Lambert v. California*, 355 U.S. 225 [1957]). (See also NEGLIGENCE.)

**4. Ignorance and Mistake.**—The maxim *ignorantia facti excusat* ("ignorance of fact excuses") represents one aspect of the *mens rea* doctrine. It expresses the obvious deduction that when the accused is operating under an assumption of fact which, although mistaken, is inconsistent with the *mens rea* required to be shown, no crime is committed. Thus one who takes and carries away goods of another, believing them to be his own, does not

commit larceny, for he lacks the requisite intent to steal. So also, if the offense is one of absolute liability, a mistake of fact about a material element of the offense does not relieve the actor of liability since his mental state is irrelevant to the definition of the crime.

On the other hand, the Anglo-American law recognizes the maxim *ignorantia legis neminem excusat* ("ignorance of the law excuses no one"). Thus, in general, it is no defense that the actor was unaware that his conduct was criminal. Two principal grounds for differentiating mistake of law from that of fact have been advanced: First, it is the sole responsibility of courts and legislatures to declare authoritatively what the law is. This function could not be discharged effectively, it is asserted, if the accused's guilt is made to depend on his judgment or that of his attorney as to the meaning of the law. Second, the infliction of injury in ignorance of the relevant law does not mean that the doer was unaware of the immorality of his conduct. The doctrine that mistakes of law do not excuse seems reasonably supportable when the offense involves conduct which would be recognized as dangerous and immoral by any responsible adult. The matter is much less clear, however, when the case is one of a statutory offense prohibiting conduct that is not obviously dangerous or immoral. A substantial body of opinion would permit mistakes of law to be asserted in defense of criminal charges in such cases, particularly when the defendant has in good faith made reasonable efforts to discover what the law is. In Germany and some other continental countries an even wider scope to the defense of mistake of law appears to be recognized. (See also *IGNORANCE*.)

**5. Responsibility.**—It is universally recognized that, in appropriate cases, persons suffering from serious mental disorders should be relieved of the criminal consequences of their conduct. This principle has been part of the English common law for at least seven centuries. There is little controversy regarding the justice and utility of the basic proposition. Sharp and persistent differences of opinion have been expressed, however, regarding the proper statement of the legal tests of responsibility. (See *INSANITY*.)

In Anglo-American jurisdictions the law of responsibility rests primarily on the famous case of *McNaghten* (10 Cl. and Fin. 200 [1843]). In that case the judges of England, in response to questions propounded by the house of lords, announced that "... to establish a defence of insanity, it must be clearly proved that, at the time of committing the act, the party accused was labouring under such a defect of reason, from disease of the mind, as not to know the nature and quality of the act he was doing; or, if he did know it, that he did not know it was wrong." The federal courts and those of about one-quarter of the states have supplemented the McNaghten rules by the so-called irresistible impulse test, which also relieves the accused of criminal responsibility if he could not control his behaviour because of mental disorder.

The McNaghten rules have been the object of sharp controversy since the date of their formulation. Critics have charged, for example, that they express an overintellectualized concept of mental disorder, reflecting outmoded notions of human behaviour. Since the rules are not based on modern concepts of medical science, the psychiatrist finds it difficult to translate his learning into the legal formula, thereby depriving the court of the full benefit of his knowledge and insight. Many other criticisms of varying degrees of cogency have been advanced. The McNaghten rules have had staunch defenders, however, even among members of the medical profession; and the courts have almost unanimously resisted arguments to abandon them. An important development occurred with the 1954 decision of *Durham v. U.S.*, 214 F. 2d 862, by the court of appeals for the District of Columbia. The Durham decision specifically rejected the McNaghten rules as supplemented by the irresistible impulse test, which theretofore had been recognized in the District of Columbia, and adopted a new test derived from earlier decisions of the New Hampshire court. The Durham test, as expressed by the court, is "simply that an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect." Although supported by some lawyers and judges and by a larger number of

psychiatrists, the Durham rule has also been criticized by some commentators. It was adopted by legislation in the Virgin Islands in 1957. Other efforts to formulate a new legal test of responsibility were made in the 1950s. Among the most important of these were proposals made by the royal commission on capital punishment (1949-53) in England and by the American Law Institute's model penal code. The latter proposal was adopted by statute in Vermont and Illinois, and a version of it was accepted by a federal court of appeals.

Even when the accused's mental disorder is not so advanced as to result in irresponsibility, it may nevertheless affect the extent of his criminal liability. Some U.S. courts have permitted the accused to show that his mental condition rendered him incapable of forming the *mens rea* required for a more serious offense, thereby reducing the grade of the offense for which he is convicted. Thus, if the defendant is able to demonstrate that he was incapable of premeditating, his offense may be reduced from first- to second-degree murder. The "diminished responsibility" provisions of the English Homicide act, 1957, recognize a more comprehensive principle similar to that expressed by the law of Scotland and some continental countries. Section 2 of the act provides that a person who kills another shall not be guilty of murder "if he was suffering from such abnormality of mind ... as substantially impaired his mental responsibility for his acts or omissions in doing or being a party to the killing." The effect of this section is to reduce an offense of murder to manslaughter.

**6. Infancy.**—Another aspect of criminal incapacity is that recognized in children of tender years. At the common law no child below the age of seven was regarded as possessing criminal responsibility. A presumption of incapacity applied to children 7 years of age or over and not yet 14. The presumption could be overcome by a showing that the child understood the nature and consequences of his conduct. English history reveals actual instances of the execution of capital punishment on children ten years of age and even younger. In most states of the U.S. the minimum age of capacity has been raised by statute. Illinois, for example, sets the minimum age at ten years. The criminal capacity of children has been further modified by the widespread enactment of juvenile-court laws. Under some of these laws the juvenile courts have exclusive jurisdiction over the delinquencies of children until they attain a specified age, usually 17 or 18. In other states, jurisdiction of the juvenile court is concurrent with that of the criminal court. Under such laws a child over the minimum age of capacity may be tried either as a delinquent in the juvenile court or as a criminal in the courts of general criminal jurisdiction. (See also *CHILDREN'S COURT*.)

**7. Intoxication.**—The Anglo-American law takes an ambivalent and unsatisfactory position on the significance of intoxication to criminal liability. Some of the early common-law commentators, such as Lord Coke writing in the 17th century, expressed the view that voluntary drunkenness, far from providing a ground for mitigation of penalties, should be regarded as an aggravation of the wrong. This extreme position seems never to have been taken by any court; but it is commonly said, even today, that intoxication is no defense to a criminal charge. The statement, however, does not mean that drunkenness has no significance in determining the existence or the degree of criminal liability. Anglo-American jurisdictions generally recognize that drunkenness may affect the capacity of the accused to form the *mens rea* required for the commission of an offense. Where this is true the accused may escape liability or be found guilty of a less serious offense. Thus, one so inebriated that he lacks capacity to form an intent to steal is not guilty of larceny even though he takes and carries away the goods of another. In homicide cases the chief significance of the intoxication defense is to reduce a charge of first-degree murder to one of second degree or, in English law, from murder to manslaughter, on a finding that the accused was incapable of premeditation. The Anglo-American law does not adequately reflect the increased knowledge, acquired chiefly since World War I, of the relationship between persistent drunkenness and some types of mental disorder. There is reason to believe that the law gives inadequate recognition to the fact that many

crimes committed in a state of inebriation are the product of serious mental disease in the offenders. (See also LIQUOR LAW.)

**8. Vicarious Liability.**—The common law of crimes ordinarily proceeds on the assumption that "guilt is personal." Thus, in general, a person may be held criminally accountable for the conduct of another only when he in some way participated in or contributed to the conduct. During the 19th and 20th centuries, however, legislatures in England, the commonwealth countries and the United States created numerous statutory offenses in which the basis of liability is the existence of an employment relationship between the accused and the person engaging in the criminal act. Perhaps the most common of these relate to the regulation of the liquor trade. Thus, the owner of a retail liquor establishment may be held liable for the sale of alcoholic beverages to a minor or the sale of liquor after the closing hour, even though the acts were committed by an employee contrary to the instructions and wishes of the defendant. In the case of *U.S. v. Dotterweich*, 320 U.S. 277 (1943), the U.S. supreme court affirmed the conviction of a corporation president for introducing misbranded drugs in interstate commerce although there was no proof that the defendant actively participated in the criminal act or even knew of its occurrence. The facts encouraging the expansion of vicarious criminal responsibility are similar to those that encouraged creation of absolute liability; and the objections to the one may be equally applied to the other. As in the case of absolute liability, some U.S. courts before the end of the 1950s expressed hostility to the unrestricted expansion of vicarious criminal responsibility. Thus a Pennsylvania court held that the imposition of a jail sentence on a tavern proprietor for the unauthorized acts of an employee violated the defendant's constitutional rights. A majority of the court, however, recognized the power of the state to impose a monetary fine on the proprietor in such circumstances. (*Comm. v. Koczwara*, 397 Pa. 575 [1959].)

**9. Corporations and Associations.**—The criminal responsibility of corporate bodies and of such private associations as partnerships and labour unions constitutes one type of vicarious criminal responsibility. Ordinarily a corporation is held criminally liable for the act of an officer or employee, but a fine levied on the corporate body involves loss to the stockholders, who, in most instances, did not participate in the criminal act and were unaware of its occurrence. The objections to vicarious responsibility are less cogent in the corporate case, however, since the stockholders do not suffer the stigma of being personally convicted and their loss is limited to the amounts of their investment in the corporation.

Some statements made in the early history of the common law deny the possibility of holding corporate bodies criminally liable for acts of their agents. But beginning about the third decade of the 19th century courts both in England and the United States imposed criminal liability on corporations in a substantial number of cases. These early cases recognized various limitations on corporate responsibility, the most important being that a corporation might not be held liable for an offense requiring proof of a criminal intent. This and other restrictions were quite generally abandoned during the course of the 19th century. By mid-20th century the most important practical limitation on the scope of corporate responsibility was the failure of the legislatures, in defining certain offenses, to authorize penalties that could be applied to a corporation. Another question of some importance relates to the class of persons whose acts are attributable to the corporation for purposes of criminal liability. It appears to be the rule in New York and of some English cases that the conduct must be that of a director, officer or high managerial official. In many U.S. cases, however, corporations have been held liable for the criminal acts of minor employees. The criminal liability of private associations other than corporations is much less clearly defined. Federal criminal statutes, in particular, frequently authorize imposition of fines on such bodies, and in a number of cases these penalties have been applied.

**10. Parties to Crime.**—A person may be held legally accountable for the conduct of another through the doctrines of accessoryship. The common-law doctrines were elaborate and cumbersome.

The accessory before the fact was one who encouraged or advised another to commit an offense. The principal in the second degree was one present when the crime was committed who aided and abetted the principal offender. The party committing the criminal act was known as the principal in the first degree. In misdemeanour and treason cases all participants were treated as principals in the first degree. When the party who was persuaded to commit an offense lacked criminal capacity by reason of infancy or mental disorder, he was regarded as an "innocent agent"; and the person instigating the conduct was treated as a principal in the first degree. At common law an accessory could not be indicted as a principal in the first degree. An acquittal of the principal relieved the accessory from criminal liability. Although the common-law nomenclature is still generally employed in criminal legislation, the clear tendency of the modern U.S. law is to eliminate the common-law distinctions between accessories and the principal offender and, for most practical purposes, to treat all participants in an offense as principals in the first degree. Distinct from the foregoing categories is the accessory after the fact. Such a party does not share in the guilt of the principal in the first degree but is made punishable for concealing or obstructing the apprehension of one known by him to be a fugitive from justice.

**11. Consent and Condonation.**—The proposition, sometimes expressed, that consent of the victim to the criminal conduct of the accused is no defense requires considerable qualification. In cases of homicide, dueling and other instances of serious bodily injury, consent of the victim does not excuse the criminal behaviour. The English Homicide act, 1957, provides, however, that a killing by the survivor of a suicide pact shall be manslaughter, not murder. Prize fighting and other athletic contests involve behaviour which would constitute a criminal assault but for the acquiescence of the other participants. In a considerable number of serious offenses, lack of consent of the victim is, by definition, indispensable to commission of the crime. Thus, in forcible rape the intercourse must occur against the will of the woman. Larceny requires the taking of goods from the possession of the owner without his consent. Except in a few statutory offenses, the accused is not relieved of liability for a completed crime by the victim's subsequent condonation of the conduct.

**12. Necessity and Coercion.**—The doctrines of necessity relate to situations in which a person, confronted by the overwhelming pressure of natural forces, must make a choice between evils and chooses to engage in conduct, otherwise criminal, as the lesser of the evils. In the leading U.S. case of *U.S. v. Holmes*, 26 Fed. Cases 360 (1842), a longboat containing passengers and members of the crew of a sunken American vessel was cast adrift in the stormy sea. To prevent the boat from being swamped, members of the crew threw some of the passengers overboard. In the trial of one of the crew members, the court recognized that such circumstances of necessity may constitute a defense to a charge of criminal homicide, provided that those sacrificed be fairly selected, as by lot. Because this had not been done, a conviction for manslaughter was returned. The leading English case, *Regina v. Dudley and Stephens*, 14 Q.B.D. 273 (1884), appears to reject the necessity defense in homicide cases. This principle in some form has been recognized in the legislation of a number of continental countries, nations of the commonwealth, and of some states of the United States. The scope of the principle, however, has not been clearly or fully delineated in most Anglo-American jurisdictions.

The defense of duress or coercion relates to situations in which the accused acted under threats of imminent death or serious bodily injury by third parties. Such judicial authority as exists on the point states that the defense is not available when the accused has killed an innocent victim in order to save his own life. There are few instances in which the defense has been successfully advanced even in less serious cases, indicating that the requirements of exculpation on grounds of coercion are rigorously defined in actual application. At common law a presumption of coercion existed in most cases in which a wife committed an offense against a third party in the presence of her husband. It

is this rule which prompted the protest of Mr. Bumble in Dickens' *Oliver Twist*: "If the law supposes that, . . . the law is a ass—a idiot." The tendency of modern legislation is to eliminate this presumption. Analogous problems are posed by the commission of offenses by members of the armed forces acting under the orders of superior officers. The significance of superior orders to criminal liability is stated somewhat differently in the English and U.S. cases. Both appear to agree, however, that exculpation is not granted when the orders of the superior officer were patently illegal.

**13. Self-Defense and Justification.**—The Anglo-American law recognizes a number of particular situations in which the use of force, even deadly force, is excused or justified. The most important body of law in this area is that which relates to self-defense. In most U.S. jurisdictions deadly force may be employed whenever one reasonably believes that he is placed in imminent peril of death or serious bodily injury by the conduct of another and that the killing of the other is necessary to save his own life. Thus, justification may be granted when the killing was, in fact, not necessary, so long as the actor reasonably believed it to be so. On the other hand, an actual belief is not sufficient if it is found to have been unreasonable under the circumstances. A few U.S. jurisdictions hold that belief, even unreasonable belief, excuses; and the tentative draft of the American Law Institute's model penal code asserts this to be the preferable view. U.S. jurisdictions are divided on the requirement of a "retreat to the wall." The cases in some states hold that one who has in no way provoked the difficulty must withhold the use of deadly force until retreat is impossible or serves to increase, rather than diminish, his peril. The federal courts and probably a majority of state courts permit the defendant to stand his ground and to kill when the requirements of self-defense are met. Most U.S. jurisdictions recognize the retreat requirement when the defendant has in some manner provoked the altercation which ultimately leads to the necessity of using deadly force. When the defendant provokes the difficulty initially by feloniously assaulting the deceased, rights of self-defense may not be asserted until the accused has fully withdrawn from the altercation and has clearly communicated his intention to desist.

The Anglo-American law of justification states varying requirements for the use of force in other situations. These include the use of force to protect third parties from harm, to prevent commission of a felony, to arrest a fleeing felon and to defend property or habitation from the aggressions of another.

#### C. PARTICULAR OFFENSES

Certain types of behaviour are universally recognized as being dangerous to the security of individual and social interests. All advanced legal systems condemn as criminal the sorts of conduct described in the Anglo-American law as treason, murder, aggravated assault, theft, robbery, burglary, arson and rape. With reference to minor police regulations, however, substantial differences in the definition of criminal behaviour occur even among jurisdictions of the Anglo-American system. Comparisons of the continental European criminal law and that based on the English common law of crimes also reveal significant differences in the definition of certain aspects of more serious crimes. The continental law, for example, frequently articulates grounds for mitigation involving considerations taken into account in the Anglo-American countries only in the exercise of discretion by the sentencing authority or in the behaviour of lay juries. This may be illustrated by reference to so-called "mercy killings" (see *EUTHANASIA*). The Anglo-American law of murder recognizes no formal grounds of defense or mitigation in the fact that the accused killed to relieve the agonies of one suffering from an apparently incurable disease. In many continental and Latin America codes, provision is made for mitigation of offenses prompted by such motives, and in a few instances a defense to the criminal charge is recognized.

**1. Classification of Offenses.**—Under the common law, offenses were classified into three principal categories: treason, felony and misdemeanour. Significant consequences relating to

the penalties imposed and to the criminal procedures employed resulted from this division. U.S. jurisdictions generally distinguish between felonies and misdemeanours. Although the definition of felony is not uniform in the states, it is typically defined as a crime punishable by a term of imprisonment of not less than one year in the state penitentiary. Misdemeanours are often defined as offenses punishable only by fines or by terms of imprisonment in county or local jails. The distinction between felony and misdemeanour is less significant for the modern law, and many commentators have questioned its utility. Certain consequences continue to result from the distinction, however. Thus a convicted felon may suffer the loss of civil rights retained by the misdemeanant. Certain substantive doctrines take the distinction into account, such as that which authorizes the use of deadly force to effect the arrest of a felon, but not of a misdemeanant. In addition to felonies and misdemeanours, U.S. jurisdictions recognize a class of minor offenses that may be described as quasi-crimes. Such offenses are typically created by municipal ordinance or by county authority. Penalties are comparatively trivial. Often the right of jury trial is held not to extend to quasi-criminal proceedings, and the prosecution may not be required to establish guilt beyond reasonable doubt.

Crimes in England are classified into indictable offenses (which may be tried by jury) and summary offenses (those which may be tried summarily by magistrates sitting without juries). Indictable offenses are further divided into treasons, other felonies and misdemeanours. The remaining distinctions between treason and other felonies, however, were virtually obliterated by the Treason act, 1945. Classifications distinguishing offenses of greater seriousness from lesser crimes appear in the continental European codes. Thus the French Code Pénal distinguishes between *délit* and *contravention*, the German law between *vergehen* and *verbrechen*. (See also **FELONY; MISDEMEANOUR**.)

Other classifications of crimes have been employed for various analytical purposes. In the survey which follows, some of the major types of offenses are included in a classification of inchoate crimes, crimes against persons, crimes against property and crimes against government.

**2. Inchoate Crimes.**—The Anglo-American law defines several offenses that are sometimes labeled inchoate or preliminary crimes because guilt attaches even though the criminal purpose of the parties may not have been achieved. The first of these is an offense, usually a misdemeanour, known in England as incitement and most commonly in the United States as solicitation. The offense consists of urging or requesting another to commit a crime. With few exceptions the crime solicited must in England be an indictable offense. In the United States it is sometimes required to be either a felony or a misdemeanour involving breach of peace. The crime of solicitation is complete when the solicitation is made; the solicitor's liability does not depend upon commission of the requested offense. Criminal legislation may also prohibit certain specified types of solicitation. Examples include solicitation of a bribe or solicitation for immoral purposes, or, to take a more grave case, inciting members of the armed forces to mutiny. (See **BRIBERY; MUTINY; PROSTITUTION**.)

Criminal attempts constitute a second and more important category in inchoate offenses. Attempt consists of conduct intended to accomplish a criminal result which fails of consummation but goes beyond acts of preparation to a point dangerously close to completion of the intended harm. The line between acts of mere preparation and attempt is difficult to draw in many cases. Criminal attempt is said to require a specific intent. Thus, although in certain situations murder may be committed without an intent to kill, attempted murder cannot be established without proof of such intent. Unlike the law of some European countries, no defense is granted in the United States to an offender who voluntarily desists from committing the intended harm after his conduct has reached a point beyond mere preparation.

Conspiracy is defined by the common law as an agreement between two or more persons to accomplish an unlawful objective or to achieve a lawful end by the use of unlawful means. The offense is ordinarily said to be complete when agreement is reached,

but under some statutes, such as the federal general conspiracy law of the U.S., liability does not attach until one of the parties to the agreement commits an overt act designed to advance the purposes of the conspiracy. In the absence of statutory provisions to the contrary, the unlawful end need not be one which would be criminal if achieved by an individual acting alone. Thus, agreements to attain noncriminal ends conceived by the courts to be immoral or oppressive have been punished. Control of criminal activity involving group action is a problem of serious proportions in all advanced societies. The Anglo-American law of conspiracy, however, is far from satisfactory. Vagueness characterizes the definition of all crucial elements of the offense, and the procedures and rules of evidence applied in conspiracy prosecutions often place the defense at serious disadvantage. The European codes define a variety of offenses involving conduct of groups. But in the breadth of its scope and its amorphous quality, the offense of conspiracy in the Anglo-American law is very nearly unique. (See also CONSPIRACY.)

**3. Crimes Against Persons.**—In any advanced system of criminal justice the minimization of crimes of violence is a matter of primary concern to the legal order. The most serious of these, of course, are the criminal homicides. Murder in the Anglo-American system may be described as the killing of another human being with malice aforethought. The phrase "malice aforethought" has a technical significance and, in the course of time, has acquired meanings quite different from those commonly understood. Thus a killing may be said to be with malice aforethought when the accused intended to kill either the victim or another, intended to inflict serious bodily injury on the victim, did not intend to kill but engaged in conduct of extreme recklessness, killed another in the course of committing some other felony, or killed a peace officer while resisting a lawful arrest. All of these categories are subject to important qualifications and refinements. Most states of the U.S., beginning with the Pennsylvania statute of 1794, have divided murder into degrees, reserving capital punishment for murder in the first degree. First-degree murder is variously defined but ordinarily includes premeditated and deliberate killings and often killings occurring in the course of committing certain violent felonies. The English Homicide act, 1957, limits imposition of capital punishment to specified types of killings. The classifications of the English act, however, are substantially different from those made in most U.S. statutes.

The Anglo-American law defines a number of lesser homicide offenses. Involuntary manslaughter ordinarily involves a killing caused by the reckless or grossly negligent conduct of the offender or a homicide resulting from commission of an unlawful act other than a felony. Voluntary manslaughter is ordinarily a killing in "heat of passion" by an accused who acted in response to provocation of the victim, the provocation being of the kind which the law regards as sufficiently serious to reduce the offense from murder to manslaughter. Many states of the U.S. recognize a lesser offense, sometimes called reckless homicide, relating chiefly to deaths resulting from automobile accidents. All the European codes distinguish various grades of criminal homicide, the distinctions being based on considerations of the relative heinousness or dangerousness of the offender's conduct. (See also HOMICIDE.)

In addition to the criminal homicides the Anglo-American law defines other offenses against the person. Two of these, forcible rape and kidnaping (*q.v.*) for ransom, have been made capital crimes in some U.S. jurisdictions. Various sorts of assault and battery (*q.v.*) are punished in all states of the U.S. The common-law offense of mayhem (*q.v.*) was committed when the accused cut off or otherwise deprived another of the use of a limb or a member, thereby impairing the ability of the victim to defend himself. The crime of mayhem, usually broadened to include other kinds of serious bodily harm, has been made part of the statutory law of many U.S. jurisdictions.

**4. Crimes Against Property.**—In a developing legal system, among the first offenses to be defined and punished are those against property. Because of its antiquity and the fact that the relative importance of various forms of property alters as the

economic system develops, the criminal law of property offenses is likely to contain anachronistic elements unless subjected to continuing revision by the law-making authority. These problems clearly emerge in the Anglo-American law.

"Theft" is usually employed as the generic term encompassing the more common property crimes. The basic theft offense in the English common law was larceny (*q.v.*). The criminal act in larceny consists of the taking and carrying away of goods from the possession of another without the latter's consent. The offender must have an intent to steal (*animus furandi*), defined as an intent to deprive the owner of his goods permanently. Although the general larceny formula continued essentially unaltered throughout the latter course of its development, the actual scope of the offense was expanded by a series of judicial holdings and legislative provisions. This enlargement was achieved principally through an increasingly liberal view as to when goods were in the possession of another. Despite this expansion, the law of larceny by the 18th century was inadequate to cope with all the problems of the new commercial and industrial society. In response to these needs parliament enacted the first general embezzlement statute (39 Geo. III, c. 85), in 1799. Since embezzlement (*q.v.*) is entirely a creature of statute and since provisions defining embezzlement offenses vary considerably among Anglo-American jurisdictions, no single definition is adequate. In general these provisions relate to misappropriation of the goods of another which have been delivered or entrusted to the possession of the offender. A third important category of theft in the Anglo-American law is the crime of false pretenses. Although the origins of the law of criminal fraud are to be found in the early common law, the modern offense of false pretenses derives in large measure from the statute, 30 Geo. II, enacted in 1757. The offense ordinarily consists of inducing another to part with ownership of goods by the false representations of the accused. Akin to false pretenses is the offense of obtaining credit by fraud. Finally, the Anglo-American law punishes the receiving of stolen goods by one who knows or believes them to be stolen and intends to deprive the owner permanently of his property. Since the receiver provides the market for stolen goods, prevention of such conduct is obviously crucial to effective discouragement of large-scale thefts. Because of difficulties of proof, however, prosecutions of receivers are subject to unusual problems.

The distinctions between the various categories of theft are often difficult to draw in particular cases. The result is that offenders sometimes escape merited punishment by showing that their conduct did not constitute the particular offense charged. Effective administration of justice in this area is further handicapped by the presence of outmoded and irrational limitations on the definition of theft offenses. A number of U.S. jurisdictions, such as Massachusetts, have enacted consolidated theft laws which define a single statutory offense containing the elements of all the major theft crimes and which permit convictions upon a showing that the offender's conduct fell within any of these categories. The tentative draft of the American Law Institute's model penal code contains a notable effort to consolidate and rationalize theft law.

In addition to these major categories of theft, legislatures in all economically-developed nations have enacted a wide range of offenses relating to various aspects of modern commercial enterprise. Typical of these statutes are those adopted by U.S. state legislatures and the federal congress designed to eliminate frauds and to force full disclosure in the sale and issuance of corporate securities.

The law of advanced legal systems also makes criminal various types of conduct that constitute threats both to bodily security and to property. In the Anglo-American jurisdictions the most important offenses of this kind are robbery, burglary and arson. Robbery may be regarded as an aggravated larceny and consists of taking property from the person or presence of another by placing him in fear. U.S. statutes ordinarily authorize greater penalties when robbery is accomplished by use of a firearm or other dangerous weapon. Burglary (*q.v.*) at the common law was the breaking and entering of the dwelling house of another at night with

intent to commit a felony in the structure. In modern statutory law the offense has frequently been expanded to include buildings other than houses. The requirement that entry be made at night has sometimes been eliminated. Arson (*q.v.*) consisted of the malicious burning of the dwelling house of another. Modern law has, again, defined the offense to encompass burnings of other structures, including the dwelling house of the offender.

**5. Crimes Against Government.**—In the feudal system the most heinous offense was the breach of the allegiance owed by the vassal to his lord. So also, in the modern era, offenses threatening the security of the state are treated with exceptional seriousness. Treason is the only offense defined in the United States constitution and "consist[s] only in levying war against [the United States], or in adhering to their enemies, giving them aid and comfort" (art. iii, sec. 3). The same constitutional provision limits penalties and regulates the modes of proof in treason prosecutions. In addition to treason, a wide range of lesser "political crimes" have been defined in all countries, including sedition, theft of military and governmental secrets, and many more. The kinds of political crimes and particularly the procedures employed to enforce the law in these areas tend to reflect the political principles of the nation and the degree of tolerance afforded dissent. The definition of political offenses, however, is by no means a preoccupation only of totalitarian regimes. Increase in the number and expansion of the breadth of political crimes throughout the western world is one of the clear tendencies of 20th-century legislation. (See also TREASON AND SEDITION.)

Another important category of offenses is those that may be described as crimes against public justice and governmental processes. In the United States these include such offenses as bribery of public officials, perjury (*q.v.*), exerting improper influence on members of juries, and alteration or destruction of public records. Some of such conduct is not only made punishable by the criminal law but is subject also to the contempt powers of the courts.

### III. CRIMINAL PROCEDURE

The law of criminal procedure regulates the modes of apprehending, charging and trying suspected offenders, the imposition of penalties on convicted offenders, and the methods of challenging the legality of conviction after judgment is entered. The law in this area is called upon to advance and reconcile interests of the greatest importance. It must contribute effectively to the attainment of public peace and good order. At the same time, it must afford realistic protection to the rights of persons proceeded against by the system of criminal justice.

**1. Constitutional Limitations.**—The regulation of criminal procedure is one of the primary concerns of U.S. constitutional law. Certain protections against oppressive procedures, many of which derive from the common law and English constitutional history, are given explicit recognition in the federal bill of rights (*i.e.*, the first ten amendments of the United States constitution). Thus the 4th amendment prohibits unreasonable searches and seizures; the 5th amendment requires the use of indictment or presentment in cases of infamous crime, prohibits double jeopardy, and pronounces the general requirement of due process of law; the 6th amendment guarantees a speedy and public trial in criminal cases, the right of trial by jury, to be confronted by hostile witnesses, to have compulsory process to obtain favourable witnesses, and to be tried in the district in which the crime was committed; the 8th amendment forbids excessive bail and cruel and unusual punishments. The protections of the first nine amendments to the United States constitution, however, do not apply to the states; and the original constitutional document contained only a few provisions relating to state criminal procedures, including prohibitions of *ex post facto* laws and bills of attainder (art. i, sec. 10) and provisions regulating extradition (art. iv, sec. 2). The most significant limitations imposed by federal law on state procedures arise from the equal protection and due-process clauses of the 14th amendment, adopted in 1868. It was not until the decisions by the U.S. supreme court in such cases as *Moore v. Dempsey*, 261 U.S. 86 (1923) and *Powell v. Alabama*, 287 U.S. 54 (1932), however, that the 14th amendment was given

an interpretation importantly limiting state systems of criminal procedure. Since that time the court has applied to the states many of the specific restraints of the federal Bill of Rights, although in some areas the limitations on state authority defined by the 14th amendment are much less restrictive than those imposed on the federal government by the Bill of Rights. In addition, the constitutions of the several states contain provisions regulating criminal procedure. Some of these protections are expressed in language identical or similar to that of the federal Bill of Rights. (See also BILL OF RIGHTS, UNITED STATES.)

**2. Jurisdiction and Venue.**—Although the criminal jurisdiction of state and federal courts is subject to constitutional limitations, the rules of jurisdiction applied in most states of the U.S. are derived from the common law and in some respects are more restrictive than might be permissible as a matter of constitutional authority. The jurisdiction of a court refers to its capacity to take valid legal action. Questions of jurisdiction may relate either to the subject matter of the prosecution, the geographical limits of the court's power or whether the defendant is properly before the court. Thus, in most states, minor offenses may be tried before a magistrate or justice of the peace. Such a tribunal lacks jurisdiction to try more serious crimes, such trials being within the competence of courts of general criminal jurisdiction.

In the United States, jurisdiction over criminal conduct is primarily limited to that which occurred within the territorial limits of the particular state. Thus, when one fires a bullet across a state line and kills a victim in another state, U.S. courts have held that only the latter state has jurisdiction. In some instances, however, state legislatures have extended jurisdiction to conduct occurring outside the state but which directly affects the interests of the state or its citizens. The territorial principle has also been modified in the federal courts. Federal statutes confer jurisdiction to try various cases, including those of treason, forging or altering ship's papers, enticing desertion from military service, and bribery of a United States official, even though the conduct occurred outside the national boundaries. Another federal statute extends jurisdiction of federal courts over crimes committed on U.S. vessels and in aircraft on or over the high seas. In England, as in the United States, jurisdiction is determined primarily by reference to the territorial principle. A different view is taken in many European countries, where jurisdiction is considered as existing over nationals of the state without regard to the place where they may have committed the offense. Finally, it is generally assumed that, except in the trial of petty offenses, the presence of the defendant before the court is essential to the court's jurisdiction. In many states, however, once jurisdiction has attached, it may not be defeated by the voluntary absence of the defendant. Rule 43 of the Federal Rules of Criminal Procedure provides that voluntary absence of the defendant does not defeat continuation of the trial "in prosecutions of offenses not punishable by death."

Even assuming that a court has jurisdiction over the subject matter of the prosecution and the person of the offender, the question must be asked whether the court constitutes the proper place or venue of trial. Constitutional provisions, such as that in the 6th amendment to the U.S. constitution, generally provide that the defendant shall be tried in the district or county in which the crime occurred. The right thereby created may be waived by the defendant; indeed, the accused may request a change of venue because of prejudice against him in the community or in the court. When offenses are committed on moving vehicles, such as trains or boats, it may be impossible to determine precisely where the crime was committed. Statutes permitting venue to be laid in any county or district through which the vehicle passed have generally been upheld. Other special venue laws have also survived constitutional attack. (See also JURISDICTION.)

**3. Arrest and Search.**—The 4th amendment to the U.S. constitution and similar provisions of state law prohibit unreasonable searches and seizures. Since an arrest consists of the seizure of a person, the definition of valid arrest is subject to constitutional limitations. The constitutional criteria are held to be satis-

fied, however, by the common-law rules relating to arrest. At common law, arrest might be made either by warrant, issued by a magistrate on the basis of evidence creating reasonable belief that the person proceeded against had committed an offense, or, in some cases, without warrant. Arrests without warrant were held to be authorized in the following situations: A private person might validly arrest one whom he reasonably believed had committed treason or felony, provided that treason or felony had actually been committed. A private person could arrest a misdemeanant only when the offense involved a breach of peace and was committed in the presence of the former. Arrest powers of peace officers were said to be identical to those of private persons except that an arrest by an officer for treason or felony was valid even if no such offense had been committed, when the officer reasonably believed that the crime had been committed and that the arrested person was the guilty party. Modern legislation has often broadened arrest powers, particularly those of peace officers in misdemeanor cases. The constitutional validity of such statutes has ordinarily been affirmed by U.S. courts.

The legal consequences of illegal arrests are several. First, the arresting party may be held liable in a civil suit for damages. Second, since the use of force in effecting an arrest is usually justified only if the arrest is valid, the arresting party may be held criminally liable for injuries inflicted upon the person he seeks to apprehend. Finally evidence obtained in a search following illegal arrest may be rendered inadmissible in the criminal trial. This consequence is the result of the so-called "exclusionary rule," first recognized by the federal courts in the case of *Weeks v. United States*, 232 U.S. 383 (1914). In 1961 the U.S. supreme court ruled that the exclusionary rule must also be applied in state prosecutions. (See also ARREST; WARRANT.)

**4. Extradition.**—The process by which a party charged with a crime in another jurisdiction is apprehended and returned to that jurisdiction for trial is known as extradition. Procedures of extradition between sovereign nations are ordinarily regulated by treaty. The United States constitution deals with similar problems of interstate rendition among the various U.S. jurisdictions (art. iv, sec. 2, par. 2). These provisions direct that fugitives from the justice of another state be given up on the demand of that state. It has been held, however, that should the governor of the state of asylum refuse such a demand, the power of the federal government cannot be employed to compel him to comply (*Kentucky v. Dennison*, 24 How. 66 [1860]). If the governor orders compliance with the request of the demanding state, the arrestee may sue out a writ of habeas corpus (*q.v.*). In the subsequent judicial proceedings, issues are confined to whether the arrestee is the person named in the information or indictment, whether he was in the demanding state when the alleged offense was committed, and whether the indictment or information alleges with substantial accuracy an offense under the laws of the demanding state. The constitutional provisions, by requiring that the person proceeded against be a "fugitive" from the demanding state, create substantial problems. Thus an arrestee who became an accretory before the fact to a murder committed in another state is not subject to rendition to the state in which the murder was committed and in which he was not present. In order to meet this problem and to supplement the constitutional provisions, many states have adopted the Uniform Extradition act, which eliminates the "fugitive" requirement. The salutary reform achieved by the act has been imperiled in some states by an unduly restrictive interpretation of the statutory language (*People v. Werblow*, 241 N.Y. 55 [1925]).

Provisions somewhat similar to interstate rendition apply to persons charged with federal crimes in courts of the United States. Although the United States is a single jurisdiction and is thus not obliged to litigate the issue of transporting arrested persons from one federal district to another where prosecution is pending, early statutes and many decisions establish such a right in some cases. Rule 40 of the Federal Rules of Criminal Procedure distinguishes "nearby" districts from "distant" districts, the former including those in the state in which the prosecution is pending and those 100 miles from the place of trial. No hearing is neces-

sary if the arrestee is in a nearby district. The hearing required if arrest is in a distant district is held before a United States commissioner and is similar to hearings on extradition except that, if the prosecution is based upon an information rather than an indictment, it must be shown that there is probable cause to believe the accused is guilty of the crime charged. (See also EXTRADITION.)

**5. Interrogation and Confessions.**—A confession is a statement made out of court acknowledging the speaker's guilt of an offense. In the later history of the common law a coerced or involuntary confession was not admissible in a criminal trial. The same result is reached by U.S. constitutional law. Some U.S. decisions regard the admission of an involuntary confession as a violation of the defendant's privilege against self-incrimination, but most base their holdings on the requirements of due process of law. The scope of the confession rule has been the subject of sharp controversy. The view expressed most frequently in the older cases regards the confession as coerced only when the methods used to obtain it cast doubt on its accuracy or reliability. Beginning in the 1940s, however, the U.S. supreme court broadened the confession rule to invalidate not only those confessions that were probably unreliable but also those obtained by police methods regarded as reprehensible and improper. A voluntary confession is competent evidence of guilt, but in most U.S. jurisdictions it is not regarded as sufficient evidence of guilt. Thus, the confession must usually be corroborated by other competent evidence.

In the federal courts, additional efforts have been made to control the interrogatory practices of the police. Thus, even a voluntary confession of the arrested party is inadmissible if the police delayed unreasonably in bringing him before a magistrate and if the confession was made in the period of unreasonable delay. Among the state courts only those in Michigan have applied a similar rule to state criminal proceedings. Despite the various restrictions on the interrogatory practices of U.S. law-enforcement officers, the effect of the "judges' rules" in England is to confine police questioning within much narrower limits. The most important of these restrictions requires that when the officer charges the suspect with an offense, the suspect must be cautioned that he need not answer and that any answers will be recorded for possible use as evidence. (See also EVIDENCE: *Privilege and Public Policy*; DUE PROCESS; THIRD DEGREE.)

**6. Indictment and Information.**—In the United States, criminal prosecutions are commenced by a formal accusation verified by oath. Accusations are of three types: complaint, indictment and information. A complaint is ordinarily made by a private citizen or police officer, and its use is confined principally to cases of petty crimes. An indictment is a formal document returned by a grand jury. An information is an instrument prepared by the prosecutor. The 5th amendment of the United States constitution requires use of the indictment in cases of capital or other infamous crimes in the federal courts, but rule 7 of the Federal Rules of Criminal Procedure permits prosecutions of all but capital cases to proceed by information if the accused waives indictment by a grand jury. Waivers are frequent, and most prosecutions of even serious offenses in the federal courts are by information. Throughout the 19th century many states of the U.S. abolished the grand jury and, subject to various regulations, authorized use of informations. That such procedures do not violate the 14th amendment was established in the leading case of *Hurtado v. California*, 110 U.S. 516 (1884). Even in states retaining the grand jury, provision is usually made for waiver of indictment in some cases. Although the grand jury has been virtually abolished in England since 1933, cases tried by petty juries are based upon indictment. In the English practice, a bill of indictment may be preferred by any person and, when signed by the appropriate officer of the court, becomes an indictment.

The indictment or information must sufficiently allege the relevant facts to establish the jurisdiction of the court in which the case is tried, to provide the defendant with notice of the charges against him so that he may prepare his defense, and to protect the defendant from being tried again for commission of the same offense. Failure of the indictment in any of these respects may

subject it to a motion to quash by the defendant. In an earlier period the indictment was characterized by language of great prolixity. The tendency of the modern law has been to simplify criminal pleading and to eliminate the effects of trivial and merely formal errors. Nevertheless, the essential purposes of the charging function must still be achieved. The reforms introduced by the Federal Rules of Criminal Procedure are of particular importance. Rule 12 provides that a defense motion to dismiss the indictment may reach any defect ascertainable prior to trial which previously had been the subject of numerous pleas and motions. With regard to most of these defects, the defendant's failure to enter a motion to dismiss constitutes a waiver. But if an indictment or information is so defective as to fail to show the court's jurisdiction or to charge a crime, these failures may be asserted at any time during the proceeding and by a motion in arrest of judgment after conviction. (See also *INDICTMENT*.)

**7. Prosecution.**—In the United States, unlike England, the prosecuting function is chiefly performed by public officials elected or appointed for this purpose. Nor is this a recent development, for the office of public prosecutor emerged in the colonial period of American history. In Scotland, management of prosecutions is placed in the hands of an official known as the procurator-fiscal, whose functions are supervised by the lord advocate. The English system, however, has historically been one predominantly of private prosecution; i.e., proceedings are instituted by private individuals who employ solicitors and counsel to conduct the proceedings. In mid-20th century England, private individuals continued to initiate the great majority of prosecutions for such offenses as embezzlement and fraud. In most cases, however, prosecutions are initiated and conducted by the police, who frequently employ solicitors for this purpose. The office of director of public prosecutions was established by the Prosecution of Offenses act, 1879. The director is appointed by the home secretary and acts under the supervision of the attorney general. It is the obligation of the office to prosecute all capital cases and a variety of other cases including those of coinage offenses, offenses against the election laws and other crimes when such intervention is required in the public interest. The director is also charged with defense of criminal appeals in cases where he was responsible for the prosecution.

The prosecutor in the United States exercises a wide discretion. He cannot be compelled to initiate a prosecution. In extreme cases of nonfeasance, however, some states permit the appointment of special prosecutors to initiate and conduct proceedings in particular cases, and on occasion prosecutors guilty of abuse of discretion have been removed from office. The rules in the states governing dismissal of prosecutions by the state's attorney vary considerably. Such a motion, termed *nolle prosequi* ("not to be prosecuted") (*q.v.*), in about half the states requires consent of the court; in the remaining states, the prosecutor, like the attorney general of England, makes the ultimate decision and the court must grant the motion to dismiss. The states requiring acquiescence of the court to dismissal have usually discovered that, as a practical matter, the device does not seriously limit the prosecutor's discretion.

**8. Double Jeopardy.**—The 5th amendment of the United States constitution provides that no person shall "be subject for the same offense to be twice put in jeopardy of life or limb." Similar provisions are to be found in almost all state constitutions in the U.S. In general, once jeopardy has attached, an accused may not be tried again for the same offense, whatever the outcome of the first trial. Jeopardy is said to attach when the jury is sworn or, if the accused is tried without a jury, when the first witness is sworn. Certain exceptions to the general rule permit a second trial when the first proceeding is brought to a premature end by such circumstances as the illness or death of the trial judge or by failure of the jury to agree on a verdict. A new trial ordered by an appellate court when the criminal appeal was initiated by the convicted defendant does not constitute double jeopardy. In England, however, new trials are not ordered by the court of criminal appeal even when the conviction is quashed. New trials following an appeal by the state are not permitted in most U.S.

jurisdictions, although such a procedure in a state court was held not to violate the 14th amendment in *Palko v. Connecticut*, 302 U.S. 319 (1937).

The most difficult problems of double jeopardy involve the question whether the second prosecution is for the "same" or a "different" offense. It is everywhere held that acquittal or conviction of an offense prohibits subsequent prosecution of a lesser included offense (e.g., manslaughter is included in murder). The converse of the proposition is denied in a few states, however, and the protections against double jeopardy are there weakened by permitting prosecution of the more serious offense after conviction or acquittal of the included crime. The fact that offenses are defined in two different sections of the statutes does not prevent them from being regarded as the "same" offense for purposes of double jeopardy. The test applied in the federal courts is that two offenses are different if each offense requires proof of a fact that the other does not. Some of the state courts apply a broader test and hold that the offenses are the same if they arise from the same "transaction." Thus, an offender who sells illegal narcotics in his possession may not be convicted of both sale and possession. It has been held that if the same conduct constitutes a violation of the state and federal law, the offender may be prosecuted in the courts of both jurisdictions. By the beginning of the 1960s, however, an increasing number of state laws had prohibited state prosecutions following acquittals or convictions in the federal courts for offenses involving the same conduct.

**9. Proof of Guilt and Fair Trial.**—It is a basic principle of the Anglo-American law of crimes that guilt of a criminal offense must be established beyond a reasonable doubt. The proposition does not require absolute certainty of guilt by the fact finder, but it does assume a higher order of proof than that normally required in civil proceedings; i.e., proof by a preponderance of the evidence. In some jurisdictions minor offenses, usually those defined by municipal ordinance rather than state law, may be established by a mere preponderance of evidence. Some states of the U.S. place a burden of proof on the defendant to maintain certain special defenses, such as insanity. With these exceptions, the prosecution's burden of proof beyond reasonable doubt extends to all material elements of the crime. One of the material elements of a crime is the *corpus delicti* ("the body of the crime"), which means simply that commission of the crime charged must be proved. Contrary to popular belief, the *corpus delicti* requirement does not obligate the prosecution to produce the body of the victim in a homicide case; several reported decisions have resulted in conviction of the accused even though the victim's body could not be recovered, the death of the victim being established by circumstantial evidence.

One of the central concerns of the administration of criminal justice is to provide the accused with a fair hearing on the issue of guilt or innocence. A number of constitutional provisions in the U.S. refer expressly to various aspects of fair trial, notably the 6th amendment of the federal constitution with its provisions for trial by jury, speedy and public trial, confrontation and compulsory process. The right of jury trial, except in cases of certain trivial offenses, is recognized in both the federal and state courts, although in the latter juries of less than the 12 required at common law have been held not to offend the federal constitution. Decisions under the equal-protection clause of the 14th amendment have reversed state convictions when members of racial groups were discriminated against in the selection of grand and petit juries. In practice, juries are employed in a relatively small fraction of criminal cases. In most jurisdictions, considerably more than half the convictions follow upon pleas of guilty; and even when the defendant contests his guilt, he is ordinarily permitted to waive his right to jury trial. Rule 23 of the Federal Rules of Criminal Procedure permits the defendant to be tried without a jury if he "waives a jury trial in writing with the approval of the court and the consent of the government." In England, trial by jury is preserved in cases of indictable offenses, whereas petty offenses are tried summarily by magistrates. Under modern legislation, however, the two categories are not mutually exclusive;

some indictable offenses may, under certain circumstances, be tried summarily, and petty offenses punishable by more than three months' imprisonment may be tried on indictment.

Since the 1930s the United States supreme court has considered a wide range of issues relating to fair trial in the state courts, arising under the due-process clause of the 14th amendment. Some of the most important of these relate to the rights of counsel. In England, the right of one accused of a felony to employ counsel and to be represented by him in court was not fully recognized until the 19th century. It was no doubt the purpose of the provisions of the 6th amendment, guaranteeing rights of counsel in the federal courts, simply to permit a defendant to employ and be represented by counsel of his own choice. In the case of *Johnson v. Zerbst*, 304 U.S. 454 (1938), however, the 6th amendment was interpreted as requiring the court to appoint lawyers in felony cases to represent defendants lacking means to employ counsel. This broad rule has not been applied to the state courts. By the beginning of the 1960s the supreme court had announced that due process requires appointment of counsel for indigent defendants in all state capital cases, but in other cases only when necessary to ensure a fair trial. Since World War II many states have expanded their programs of legal aid, and several provide counsel to the indigent in all felony cases and, occasionally, in trials for misdemeanours. In England, legislative provision is made for legal aid when the prisoner is too poor to secure assistance and when it appears desirable in the interests of justice that legal aid be provided. (See also JURY; PRACTICE AND PROCEDURE.)

**10. Sentencing Practices.**—In the United States, sentencing powers usually reside in the trial judge. Some jurisdictions authorize the jury to make recommendations to the court in capital cases and, under some statutes, the recommendations are binding on the judge. In a few states, juries have been granted additional sentencing powers and are required not only to return a verdict on the issue of guilt but to specify the term of imprisonment to be imposed. Sentencing statutes vary considerably in their provisions, some authorizing only sentences for a definite term of years and others providing for a term with stated maximum and minimum limits. In most states, parole boards, subject to various requirements, are authorized to release prisoners under supervision before expirations of the maximum periods of imprisonment. Under the Federal Rules of Criminal Procedure and the law of a few states, a presentence investigation by the probation service and a report to the trial judge must be made before imposition of sentence or the granting of probation, unless the court directs otherwise. Although the judge is not required to adopt any recommendation made in the report, the provision for investigation and a hearing to consider questions of mitigation or aggravation are regarded as aids to a sound individualization of the sentence within the limits of permitted discretion. The trial judge may suspend the execution of the sentence or he may place the convicted offender on probation for a definite time under prescribed conditions, which usually include supervision by a probation officer. (See also PROBATION.)

**11. Postconviction Procedures.**—After conviction, a defendant may move in the trial court to arrest judgment or he may file a motion for 'new trial.' Among the grounds most frequently asserted in such motions are that the verdict is not supported by the law or the evidence; that newly discovered evidence has come to light; and that the court erred in its rulings on the admission of evidence. In modern practice, the legality of the conviction may also be challenged by review in an appellate court. Criminal appeals were unknown to the common law. In the 19th century a limited form of review was established in England by the creation of the court for crown cases reserved (11 and 12 Vict., c. 78). It was not until the Criminal Appeal act, 1907, however, that appellate review of criminal convictions was placed on a modern and satisfactory basis.

Criminal appeals play a more important role in the administration of criminal justice in the United States than in England. It was not until 1879, however, that writs of error in criminal cases were authorized in the federal practice. Provisions for criminal appeals were made in many of the states at somewhat earlier

dates. It has been held that the states are not under constitutional obligation to provide appellate review; but if criminal appeals are authorized, they must be conducted fairly and without discrimination. In addition, certain postconviction remedies performing specialized functions are available in most U.S. jurisdictions. The writ of habeas corpus may be employed to attack a judgment of conviction by challenging the jurisdiction of the trial court. The common-law writ of error *coram nobis* is recognized in some states and may result in the granting of a new trial upon a showing of facts not brought previously to the attention of the judge which might have altered the outcome of the trial had they been known to him. In some states and in the federal courts, statutory postconviction remedies are available, usually for the purpose of litigating alleged deprivations of the accused's constitutional rights at or before trial. (See also APPEAL.)

**12. Continental Countries.**—The criminal procedure of modern European countries presents many points of difference from that of countries in the Anglo-American tradition. These differences do not encompass fundamental objectives, however, for the continental law also seeks to advance public peace and order through methods which protect the legitimate interests of suspected or accused persons. The preliminary investigations of crime are principally in the hands of the police and public prosecutors. Judicial officers also participate in preliminary investigations to a degree unknown in most Anglo-American countries. Juries were introduced into continental procedure in cases of serious offenses as a result of their establishment in France after the French Revolution, and various modifications have occurred in the jury institution in the intervening years. Ordinarily the jury does not render a general finding on the issue of guilt but responds to a series of interrogatories submitted to it. Unlike the Anglo-American system which relies principally on examination and cross-examination by counsel, interrogation of witnesses is primarily the function of the presiding judge.

Williams, *Criminal Law: the General Part* (1953); Courtney Stanhope Kenny, *Outlines of Criminal Law*, 17th ed. by J. W. Cecil Turner (1958). (F. A. A.)

**CRIMINOLOGY** is the study of the causation, correction and prevention of criminal behaviour. It is not a clearly distinct and integrated science but rather one that collects the contributions of diverse specialists who study crime (*q.v.*) and related phenomena. Accordingly, the term "criminologist" does not designate a particular occupation but is applied to certain sociologists, psychiatrists, psychologists, lawyers, police officials, prison administrators, parole and probation officers and others who specialize in some aspects of criminology. In Europe writers on criminology have come mainly from university faculties of law and medicine, while in the United States criminology specialists generally are in university departments of sociology. The study of scientific crime detection techniques in police training schools also has been called criminology or scientific criminology, although where it is taught in universities, and especially as it involves the application of the physical sciences to crime detection, it increasingly is termed criminalistics (see INVESTIGATION, CRIMINAL: *Scientific Aids*). The study of methods of handling convicted criminals is a branch of criminology, sometimes distinguished as penology but increasingly called correction.

**Causation.**—The explanation of crime has always been the central concern of criminological inquiry. Early 19th-century research attempted to relate fluctuations in the amount or nature of crime to variations in climate and other aspects of the physical environment. The rise of the theory of evolution led later to a stress on heredity as the cause of crime. Most influential in this orientation was the Italian physician Cesare Lombroso (*q.v.*), who described the so-called criminal type as having peculiarities of physical appearance, particularly skull deformities, which were said to constitute a throwback to primitive man. Opposing this

view, the French magistrate and psychologist Gabriel Tarde contended that crime was learned only from association with other criminals. Meanwhile, European socialist writers of the 19th century ascribed crime to poverty rather than heredity. Early in the 20th century a British investigator, Charles Goring, greatly weakened Lombroso's influence when he reported finding about as many cases of Lombroso's criminal physical traits among English university students as among English convicts. Goring and others still assumed criminality to be hereditary but ascribed it to mental deficiency not correlated with the physical stigmata that Lombroso postulated.

In the first quarter of the 20th century the U.S. psychiatrist William Healy was among the most influential of many who promoted the idea that crime results from many factors operating together, the so-called multicausal theory. Their research method was to prepare a case analysis of each individual offender, noting as causes of criminality any marked deviation from presumed normality in health, personality, school record, home or other conditions. The English psychologist Sir Cyril Burt applied the same method in London, with findings much like Healy's. In the 1940s Sheldon and Eleanor Glueck extended this approach by measuring several hundred attributes in 500 delinquents and in a matched sample of nondelinquents in the Boston, Mass., area. They concluded that delinquents differed from nondelinquents in more often being impulsive, aggressive, hostile, poor learners in school and of mesomorphic (husky) body build and having inconsistent, discordant or criminal parents.

Since a tremendous variety of conditions may be demonstrated to be associated with some—or even most—crimes or criminals, the mere contention that crime has many causes has limited utility as a contribution to science or as a practical guide for dealing with criminals, unless rules for interrelating factors are formulated. Therefore there have been continued efforts to set forth a single theory that may account for almost all crime, or for specifiable types of criminal behaviour, without being incompatible with the evidence that many conditions have some correlation with crime.

Psychoanalytic and psychiatric writers view crime as a symptom of disturbing experiences in the intimate relationships of the family during the early years of life. In interpreting criminal cases they focus on one or more of such personality attributes as weak ego development, with resulting impulsiveness of acts, gross emotional instability and lack of guilt feeling. Traditionally, psychiatrists refer to the latter symptom as the primary basis for diagnosing "psychopathic personality." Early use of this diagnosis added the adjective "constitutional" to imply that such apparent absence of conscience was caused by inherited mental defect or by brain injury, but post-World War II writers increasingly ascribe those symptoms to defective early socialization, and the term "sociopath" became widely preferred to "psychopath."

In the 1939 edition of his *Principles of Criminology*, the U.S. sociologist Edwin H. Sutherland first presented his differential association theory as a general explanation for crime causation. This theory views crime as the normally learned behaviour of individuals who are exposed so much earlier, more intensely, more frequently or longer to procriminal behaviour that its influences outweigh those of anticriminal behaviour. Conditions correlated with crime, such as broken homes, retardation in school, high delinquency neighbourhoods, idleness or other factors which were stressed in the multicausal theory, are seen as determining crime only as they affect an individual's associations with criminal or with anticriminal behaviour. This principle of explanation was applied by Sutherland to all classes of crime, including white-collar crime, an otherwise confusing phenomenon of the deliberate violation of law by responsible persons of respectability and high social status in the course of their ordinary occupations. Research by Donald R. Cressey suggests the inadequacy of the theory for explaining embezzlement (if that act is defined as criminal violation of trust committed by persons previously trustworthy), and Edwin M. Lemert's research suggests the theory's inadequacy in accounting for simple forgery, an offense frequently associated with chronic alcoholism. Sutherland's theory has never been tested to the satisfaction of many criminologists, but its pro-

ponents contend that it is useful in the interpretation of most larceny, burglary and robbery cases, which account for 90% of major offense arrests in the U.S. and about 85% of indictable crimes known to the police in England and Wales.

During the second quarter of the 20th century, U.S. criminologists increased their concern with so-called organized crime and vice—business enterprises established to sell illegal commodities or services, such as gambling, prostitution, illegal liquor, narcotics and violent "protection." Such offenses, in which the presumed noncriminal is likely to seek the service of criminals, contrast with predatory crimes, in which there is clearly a victim who opposes the criminal. Large-scale criminal syndicates appear to have used wealth from the sale of alcoholic liquors during the prohibition period, and later from gambling, prostitution and the drug traffic, to invest in many legitimate enterprises and, in some cases, to enter politics. Their participation here becomes illegitimate when they employ violence or other illegal methods to combat their competitors. State and federal investigations and the hearings of U.S. senate committees in the 1950s, notably the so-called Kefauver committee, focused attention on the national ramifications of criminal organizations and led to some increased prosecution and regulatory legislation. Periodic scandals and exposés in other countries similarly illustrate the continuous need to be alert that crime does not become a part of the routine operation of respected business and governmental agencies.

**Correction.**—The history of the treatment of convicted criminals may be summarized as a sequence of retribution, restraint and rehabilitation. In this succession, however, older principles never were completely abandoned when emphasis shifted to newer concerns.

Almost the sole principle in early action against convicted criminals appears to have been the imposition of suffering equal or greater than that which the crime created. Until well into the 19th century, penalties consisted almost entirely of public degradation, corporal punishment, execution or banishment, accompanied by fines or confiscation of property.

The use of imprisonment as a penalty rather than merely for pretrial confinement was at first infrequent. It began to be reported in the 13th century, when life imprisonment was ordered if mitigating circumstances barred the death penalty or when imprisonment was used as a means of assuring collection of fines (the offender being released when his friends or relatives paid the required amount). From the 16th to the 18th century, imposition of imprisonment increased for lesser offenses, apparently motivated in part by a labour shortage concomitant with the growth of commerce. Prisoners were used extensively to operate galleys on coastal and inland waterways, and workhouses were created for "sturdy beggars." One of the first of these institutions, the Bridewell, which opened in London in 1553, has provided a nickname for similar establishments throughout the English-speaking world. In the 18th century a labour surplus developed, particularly in England, and in this period there was a great increase in punishment by death and by forced transportation to overseas colonies.

Only in the 19th century did imprisonment come to predominate among penalties for crime, its increase being associated with a reaction against the cruelty and ineffectiveness of capital and corporal punishments. This in turn seems to have reflected certain characteristics of the philosophy of the Enlightenment, particularly the increased respect for humanity and a heightened valuation of freedom, denial of which was viewed as one of the most severe penalties possible. The number of offenses punished by death in England is reported to have dropped from about 350 in 1780 to 17 by 1839, with imprisonment being the alternative penalty. The writing considered most influential in promoting such change was *Essay on Crimes and Punishments*, by Cesare Beccaria (1764), which appeared in 1764 and was widely translated and reprinted. It was long ascribed to Voltaire, who also was an influential critic of penal practice.

A distinctive feature of 19th-century law was the fixing of a precise duration of confinement as the appropriate penalty for each crime, in contrast to more indefinite periods prescribed earlier. The definite sentence principle reflected the philosophy of util-

tarianism, which influenced law, especially through the writings of Jeremy Bentham. He proposed to deter crime by a "hedonistic calculus" to determine penalties of restraint of freedom just sufficient to make the pain consequent to committing a crime clearly exceed the potential pleasure which might be gained from committing the crime. Any pain beyond this amount was considered unnecessary, hence unjust. While this balancing would seem to be a matter of exacting retribution, it was justified in terms of a psychological theory of human behaviour. The criminal was viewed not as having to pay for his crime but as being adequately punished if he and others merely were deterred as a result of the pain of restraint. The psychology involved in this approach can be criticized as unrealistic in assuming highly rational calculation by the offender and in neglecting the offender's consideration of his chances of not being apprehended. However, it paved the way for other judicial and correctional developments concerned with trying to change the mentality of offenders.

One such development was that of the Quakers in Pennsylvania. Under this Pennsylvania system of confinement the prisoners, instead of being housed and worked together in large halls, as was the practice in earlier prisons, were kept in solitary confinement, with only a Bible as reading matter, and were visited only by preachers and other respected persons. The Walnut street jail in Philadelphia was modified to this pattern between 1791 and 1801, and the Eastern State penitentiary, the first institution designed purely for this solitary penitence, was opened at Philadelphia in 1829. Opposition to the Pennsylvania system as being too costly and as allegedly producing insanity was spearheaded by supporters of a system named after New York's Auburn prison, constructed in 1816. The Auburn system featured small cells designed for solitary sleeping only, with waking hours devoted to congregate but silent work. The lock step and striped suit were later Auburn innovations. Alexis de Tocqueville is perhaps the most famous of many visitors from other countries sent to the United States specifically to study these penal developments. The Auburn system soon predominated in American correctional practice, but the Pennsylvania system was most widely copied in Europe. The convict prison at Pentonville in London (1842) was architecturally modeled on Pennsylvania's Eastern State penitentiary and became a prototype for more than 50 others, most of which remained in use in the second half of the 20th century.

A prison opened at Elmira, New York, in 1876, was the first of numerous establishments for young offenders to be called reformatories. On the whole, these institutions gave greater emphasis than other prisons to augmenting the academic and vocational education of inmates. In Great Britain the report of the Gladstone committee of 1895 on the general failure to reform youth led to a series of experiments culminating in 1908 with the establishment of a special program for youths in Borstal prison, near Rochester, Kent. Thereafter all institutions of a separate British system of prisons for selected 16- to 21-year-old inmates have been called Borstals. These institutions were distinguished at first by the extent to which they were staffed by idealistic members of the upper classes, who also provided extensive voluntary postrelease assistance through local Borstal associations, but volunteer participation declined sharply during the 1930s. In the United States the federal Youth Corrections act (1950) copied the Borstal sentence's guarantee of at least one conditional release from confinement before the end of the sentence in all but extremely intractable cases. (See also BORSTAL SYSTEM; REFORMATORY; PRISON.)

Probably the most important correctional development of the late 19th century was the introduction of probation and parole, which are ways of serving penal sentences under supervision in the free community. The first use of probation (*q.v.*), which is imposed by the court as an alternative to imprisonment, generally is ascribed to the efforts of John Augustus, in Massachusetts, starting in 1841. Similar practice developed in many places, however, as an outgrowth of the suspended sentence. Parole, a conditional release from prison after serving a portion of a sentence under confinement, generally is traced to a ticket-of-leave system introduced in prisons of Australia and Ireland in the 19th century. Supervision of the offenders in the community is similar under

both probation and parole, and either type of freedom may be revoked for violation of regulations, as for failure to endeavour to work regularly or to avoid known criminals. Increasingly, however, goals stressed in supervision have been not so much restriction of the offender as positive assistance and guidance. A distinctive feature of 20th-century crime correction, both in and out of prisons, has been the increased employment of psychiatrists, psychologists, social workers and sociologists for classifying offenders so that they may be placed in the available, vocational, educational or treatment program best suited to their needs, and to provide counseling and other aid.

Systematic research in correction at first consisted mainly in exposing cruel or unsanitary prison conditions. The most influential undertaking of this sort was John Howard's *State of the Prisons in England and Wales*, which appeared in 1777. Donald Clemmer's *The Prison Community*, in 1940, was the first major sociological study of a prison, not followed by others until Gresham M. Sykes' *Society of Captives*, in 1958. Criminological prediction research, an effort to guide parole and probation selection by systematic tabulation of the postrelease behaviour of different types of offenders, began with a pioneer study by Ernest W. Burgess in 1928, followed notably by the efforts of Sheldon and Eleanor Glueck, Lloyd E. Ohlin and others.

The beginning of correctional research on a major scale in Great Britain was marked by the publication, in 1955, of *Prediction Methods in Relation to Borstal Training*, by Hermann Mannheim and Leslie T. Wilkins. In 1958 Wilkins also helped California establish an extensive state program. The growing government programs attempt to evaluate the treatment of criminals statistically by determining the extent to which those treated revert to crime and by conducting some controlled experiments in correctional practice. Evaluation research in the United States often is hampered by difficulties in procuring national arrest records of released offenders in order to know more completely how many discharged prisoners or probationers get into further difficulty with the law. However, this type of research is expected to produce more scientifically adequate foundations not only for correctional practice but for criminological theory as well.

**Prevention.**—The study of juvenile crime, commonly called delinquency, has led to programs endeavouring to prevent crime by altering conditions believed to foster delinquency. Variations in prevention programs reflect different emphases in theories of crime causation.

Psychiatric and psychological research on crime has provided a major impetus for the promotion of child guidance clinics as crime prevention undertakings. These have concentrated their attention primarily on neurotic and emotionally unstable children, whether or not they were involved in crime. Most clinics receive a disproportionate number of such children from middle-class homes, for middle-class parents are more likely than working-class parents to perceive of such children as requiring psychiatric attention. However, working-class homes provide a majority of delinquency cases brought into court.

A series of studies of juvenile delinquents by Clifford R. Shaw and Henry D. McKay, initiated in the 1920s and continued for over 30 years, led to their leadership in the neighbourhood approach to crime prevention. The principal findings of their research, which have passed the test of time fairly well, include the following points: (1) Delinquency is most concentrated in city slum neighbourhoods located in areas where land is changing from residential to commercial and industrial usage. (2) The children of new and impoverished migrants to the city (rather than the migrants themselves) have the highest crime rates in the city. (3) Because the least attractive areas are the most accessible to new and poor migrants for residence, these neighbourhoods remain the highest delinquency areas despite successive migrations that make the population of such neighbourhoods change in racial or nationality composition. (4) Delinquency usually is group behaviour (two or more associates are involved in at least 90% of thefts by juveniles reported to the courts). (5) Delinquent gangs, which are common in high delinquency areas, promote delinquency by providing their members with prestige and loyalty, which these

youth are ill prepared to attain in more conventional social institutions.

The crime prevention programs growing most directly out of delinquent-neighbourhood research are Shaw and McKay's Chicago Area projects. These recruit slum residents to participate in neighbourhood committees that operate social and recreational centres in which juvenile gangs are involved in noncriminal group activities. Shaw and McKay and their protégés in many communities contend that a few professional persons employed for a delinquency prevention program can reach more slum youth or high crime potential by working with neighbourhood committees and gangs as units than they can by endeavouring to counsel the delinquents as individuals. They also contend that local adults or fellow gang members can communicate with the youths more effectively than an adult outsider and that slum residents can be trained so that they can effectively administer their own programs to make delinquents noncriminal.

Various compromises between the area-project approach and the traditional psychiatric case-work method of dealing with delinquents predominated in delinquency prevention programs in the U.S. in the 1960s. Under such titles as "detached workers" and "street corner workers," trained social workers were employed by major city agencies to locate and work with delinquent gangs in the slums. However, there have been objections to depending too greatly on slum-neighbourhood residents for direction of delinquency prevention programs, because of the high mobility of the more capable adults in the slum, the limited resources of most adults there and their frequent location in new housing projects where there is no long-established community leadership. Indeed, some programs have stressed use of case workers to evaluate the adequacy of slum parents and to seek aggressively to alter delinquency-producing home influences before the children become too advanced in criminality. This so-called reaching out method has been particularly promoted by the New York City youth board. It finds support from research by the Gluecks and by Walter Reckless on nondelinquents reared in high delinquency areas, which indicates that the family is the main insulator of such youth against delinquent-neighbourhood influences. (See also JUVENILE DELINQUENCY.)

A quite different approach to crime prevention involves efforts to reduce the profits of organized and professional crime, to which young offenders often graduate. Many states and municipalities have crime commissions to investigate alleged inefficiency of the police and the judicial system or to suggest new legislation. Crime prevention also is claimed as the basis for movements to legalize certain activities, such as the liquor business where it is prohibited, off-track gambling and narcotics distribution, which when not legalized are exclusively a criminal monopoly. The legalization argument contends that dissociating vices from crime reduces the resources of criminals, their interest in recruiting the innocent and their ability to corrupt police and other officials, and at the same time permits more effective regulation and treatment of the vices. Opponents to these views argue that legalization makes potential sources of vicious habits more accessible, hence vice becomes more widespread and promotes crime by impairing a person's ability to meet the responsibilities of noncriminal life.

**CRIMMITSCHAU** (KRIMMITSCHAU), an industrial town of Germany which after partition of the nation following World War II was in the *Besirk* (district) of Karl-Marx-Stadt, Saxony, German Democratic Republic. Pop. (1964) 31,074. The town is on the Pleisse river, 40 km. (25 mi.) W. of Karl-Marx-Stadt and 58 km. (36 mi.) S. of Leipzig. The Leipzig-Zwickau-Hof railway line passes through it. Crimmitschau is a textile centre. It has many factories producing cloth and knitted goods, spinning and weaving mills and textile manufacturing plants. The strike of the Crimmitschau textile machinery workers from Aug. 1903 to Jan. 1904 had the effect of mobilizing textile workers in the whole of Germany. A leader of the Crimmitschau women textile workers in this struggle was the pioneer for equal rights for women, Clara Zetkin (q.v.).

**CRINOIDEA**, a class of marine invertebrates of the phylum Echinodermata (q.v.); it comprises the attached, stalked sea lilies and the stalkless, free-living feather stars. The sea lilies, which flourished in former geological periods, are important index fossils.

See also references under "Crinoidea" in the Index volume. (EL. D.)

**CRINUM**, a genus of bulbous plants of the family Amaryllidaceae (q.v.) with fleshy leaves and a solid, leafless flower stalk bearing a cluster of handsome white or red funnel-shaped regular flowers. There are 100 or more species, native to tropical regions, some well known in cultivation.

The swamp lily, *C. americanum* (not a true lily, however), of the southern U.S., is sometimes planted for ornament. *C. bulbiferum* (or *bulbispermum*) of South Africa is the best-known garden crinum.

**CRIOBOLIUM**, the sacrifice of a ram in the cult of the Phrygian nature and vegetation deities Attis and the Great Mother. Perhaps it was a ceremony instituted after the rise and on the analogy of the taurobolium, which it probably resembled, but was in honour of Attis. When it was performed in conjunction with the taurobolium, the altar was almost invariably inscribed to both the Mother and Attis, while the inscription was to the Mother alone when the taurobolium only was performed. The criobolium was sometimes performed alone.

**CRIPPEN, HAWLEY HARVEY** (1862-1910), convicted wife-poisoner, was hanged at Pentonville prison on Nov. 23, 1910, following one of the most sensational English murder trials in the 20th century. Crippen, a U.S. citizen holding a medical degree, went to London in 1900. His wife, who affected the stage name of Belle Elmore, was a vivacious woman much absorbed in an unsuccessful career in the English music halls. Relations between Crippen and his wife deteriorated, and three years before the homicide, Crippen established an illicit liaison with Ethel Le Neve, a typist.

Mrs. Crippen was last seen alive at a social function on the evening of Jan. 31, 1910. Shortly thereafter Crippen falsely asserted that his wife had gone to the United States on family business, and later, that she had died of pneumonia. When Crippen's statements prompted investigation, he and Miss Le Neve, the latter disguised as a boy, attempted flight to America. A search of Crippen's home resulted in the discovery of mutilated human remains under the cellar floor. Crippen and Miss Le Neve were apprehended on an ocean vessel as it neared Quebec. This is believed to be the first occasion in which wireless telegraphy played a role in crime detection.

At his trial Crippen persistently and imperturbably maintained his innocence. The evidence against him, however, was overwhelming. It was established that the killing was accomplished by a lethal dose of hyoscine, a poisonous drug, and that Crippen

had purchased five grams of the poison shortly before his wife's disappearance. The remains were identified as those of Mrs. Crippen by an abdominal scar. They were wrapped in a pajama jacket traced to Crippen.

The trial was notable for the collapse of the medical testimony of the defense. The court of criminal appeal refused to disturb the conviction. Miss Le Neve was tried as an accessory after the fact and was acquitted.

See F. Young (ed.), *The Trial of Hawley Harvey Crippen*, "Notable British Trials Series," 2nd ed. (1950). One of the numerous discussions of the Crippen case may be found in Sir T. Humphreys, *A Book of Trials* (1953). (F. A. A.)

**CRIPPLE CREEK**, a city near the centre of Colorado, U.S., in a granite pocket 9,600 ft. above sea level, seat of Teller county and the heart of a gold-producing district once the richest in the world.

Gold was discovered in Poverty gulch, just northeast of the present city, early in the year 1891 by Robert Womack, a cowpuncher, who died poor; and the Independence vein, on the site of nearby Victor, was struck on July 4, 1891, by W. S. Stratton, a carpenter, who left a fortune of \$20,000,000. The gold output reached \$2,000,000 in 1893 and mounted rapidly to exceed \$18,000,000 in 1900.

From 1900 to 1910 it averaged \$15,000,000 annually, the following decade it averaged about \$10,000,000 and declined thereafter. Cripple Creek became almost a ghost town. The rise in the price of gold to \$35 per ounce in 1934, the digging of the Carlton drainage tunnel and the removal of the Golden Cycle mill to the district instilled new life. The gold production was about \$2,000,000 annually after 1950.

Three railways reached Cripple Creek during the years 1893–1901. Following fires that razed the lumber city in the 1890s, it rose in brick and stone.

In 1894 and again in 1903–04 there were serious labour disturbances, attended by violence and loss of life. The population of the district declined from 29,000 in 1900 to fewer than 1,000 after 1960. The city has become a favourite summer tourist resort. (L. R. HA.)

**CRIPPLES:** see REHABILITATION, MEDICAL AND VOCATIONAL.  
**CRIPPS, SIR (RICHARD) STAFFORD** (1889–1952), British statesman, chiefly remembered for his rigid austerity program as chancellor of the exchequer (1947–50), was born in London on April 24, 1889, the fourth son of Charles Alfred Cripps (afterward Lord Parmoor) who was a distinguished ecclesiastical lawyer. His mother was a sister of Beatrice Webb. He went to school at Winchester and from there won a scholarship to New College, Oxford, but as he wished to study chemistry he went instead to University College, London. During the early part of his life the bent of his mind remained strongly scientific and in World War I, being unfit for military service, he worked (1915–17) in the explosives department of the ministry of munitions.

Cripps's health collapsed in 1917 and he was an invalid for two years. In 1919 he returned to the bar (to which he had been called in 1913) and rapidly built up a highly successful practice based of mainly on patent cases, in which his scientific knowledge was of considerable use. In 1927 he became the youngest king's counsel of his day. During this period his interest in world problems only found religious expression. He was (and remained throughout his life) an active Anglican and a supporter of the World Alliance for Promoting International Friendship Through the Churches. Although his father, originally a Conservative, had been a member of the first Labour cabinet, Stafford Cripps belonged to no political party until 1929 when he joined the Labour party. In 1930, although not a member of the house of commons, he was appointed solicitor general by J. Ramsay MacDonald and received the knighthood which is customary for law officers. He was elected member of parliament in 1931 for Bristol East, which constituency he represented until 1950.

When MacDonald formed his national government in 1931 Cripps went into opposition with the bulk of the Labour party. However, his relations with his colleagues during the 1930s were far from smooth. He reacted to the 1931 defeat by adopting a

cataclysmic approach to socialism. In 1932 he helped to found the left-wing Socialist league. In 1935 he resigned from the Labour party national executive in opposition to the party's support for League of Nations sanctions against Italy. In 1936 he advocated a united front with the Communists and in 1938 he widened (and modified) his views to advocate a popular front and co-operation with anyone "from Churchill to Pollitt" who would stand up to Hitler. His persistence in this campaign led to his expulsion from the Labour party in 1939. During these years he was one of the most successful advocates at the bar.

In May 1940 Winston Churchill made Cripps ambassador to the U.S.S.R. He remained in Moscow until Jan. 1942. On his return he became a member of the small war cabinet, lord privy seal and leader of the house of commons, but in Nov. 1942 he transferred to a more administrative post—minister of aircraft production—which he held until the end of the war. He was then readmitted to the Labour party and joined C. R. Attlee's cabinet as president of the board of trade. In this capacity he launched Great Britain's postwar export drive, but he was also greatly occupied with the nondepartmental task of negotiating a settlement with India.

In Nov. 1947 (having been minister for economic affairs since early October) Cripps succeeded Hugh Dalton as chancellor of the exchequer. For the next three years he dominated the home policy of the Labour government. He concentrated on the balance of payments and investment, and he pursued a strict fiscal policy aimed at checking inflation by means of large budget surpluses. He earned the epithet of "austerity Cripps," but he gave moral leadership of unusual force to the country. He achieved a rapid rate of economic growth and a substantial improvement in Great Britain's trading position, but he was not able to prevent the devaluation of the pound in 1949. He was forced by illness to resign both from office and from parliament in Oct. 1950. He never recovered and he died at Zürich, Switz., on April 21, 1952.

(R. J.)

**CRISPI, FRANCESCO** (1819–1901), Italian statesman, an extreme nationalist who began his political life as a radical and ended up as the champion of monarchic autocracy, was born at Ribera, near Agrigento in Sicily, on Oct. 4, 1819. In 1846 he established himself as an advocate at Naples. On the outbreak of the Sicilian revolution at Palermo (Jan. 12, 1848) he hastened to the island and took an active part in guiding the insurrection. On the restoration of the Bourbon government (May 15, 1849) he was excluded from the amnesty and compelled to flee to Piedmont. There he eked out a penurious existence by journalism. After the Mazzinian conspiracy at Milan (Feb. 6, 1853) he was expelled from Piedmont for his republican sympathies and took refuge at Malta. Expelled from Malta for his journalistic writing, he joined Mazzini in London and continued to conspire for the liberation of Italy. On June 15, 1859, he returned to Italy, after publishing a letter repudiating the aggrandizement of Piedmont and proclaiming himself a republican and a partisan of national unity. Twice in that year he went the round of the Sicilian cities in disguise to prepare for another revolution against the Bourbons of Naples.

Arriving in Genoa, Crispi worked with A. Bertani, N. Bixio, G. Medici and Garibaldi to organize the expedition of the Thousand (see GARIBALDI, GIUSEPPE; ITALY: History). Overcoming Garibaldi's hesitation by a stratagem, he secured the expedition's departure on May 5, 1860. Disembarking at Marsala on May 11, Crispi on the 13th. at Salemi, drew up the proclamation whereby Garibaldi assumed the dictatorship of Sicily, with the program "Italy and Victor Emmanuel." After the fall of Palermo, Crispi was appointed minister of the interior. As the chief Sicilian in the revolutionary army, he virtually took over politics and the administration, but was shortly afterward obliged to resign because of the struggle between Garibaldi and the emissaries of Cavour, who wanted the island's immediate annexation. Appointed secretary to Garibaldi, Crispi secured the resignation of A. Depretis, whom Garibaldi had appointed pro-dictator, and would have continued his fierce opposition to Cavour at Naples had not the advent of the Italian regular troops and the annexation of the Two Sicilies to Italy brought about Garibaldi's withdrawal to Caprera (an island off Sardinia) and Crispi's own resignation.

Entering parliament in 1861 as extreme left deputy for Castelvetro (Sicily), Crispi acquired the reputation for being the most aggressive and most impetuous member of the Republican party, but in 1864 he made to the chamber a monarchical profession of faith in his famous phrase, "the monarchy unites us, the republic would divide us." Thus began his separation from Mazzini which marked an important point in the consolidation of the new state.

In 1866 Crispi refused to enter Bettino Ricasoli's cabinet. The following year he worked behind the scenes to make possible a Garibaldian invasion of the papal states, but in vain. Meanwhile in parliament he campaigned for universal suffrage and anticlericalism.

On the outbreak of the Franco-German War in 1870 Crispi sought to impede the projected alliance with France and to drive Giovanni Lanza's cabinet to attack and capture Rome. Urbano Rattazzi's death in 1873 induced Crispi's friends to put forward his candidature for the leadership of the left; but Crispi, anxious to reassume the crown, decided not to compete and supported the election of Depretis. After the advent of the left he was elected (Nov. 1876) president of the chamber.

During the autumn of 1877 Crispi went to London, Paris and Berlin, establishing cordial personal relationships with Gladstone and, above all, with Bismarck. The latter now became his model in politics. In Dec. 1877 Crispi at last achieved office and became minister of the interior in the Depretis cabinet. On Jan. 9, 1878, Victor Emmanuel's death enabled him to secure the formal establishment of a unitary Italian monarchy, the new monarch taking the title of Humbert I of Italy instead of Humbert IV of Savoy.

After only two months in office a storm of indignation was conjured up against Crispi in connection with a charge of bigamy, and he was compelled to resign. For nine years he remained under a cloud and in opposition to Depretis, but in 1887 he returned to office as minister of the interior in the Depretis cabinet, succeeding to the premiership on the latter's death (July 29, 1887). People now began to accuse him of lack of principle and an overmastering desire for power.

One of Crispi's first acts as premier was another visit to Bismarck. Basing his foreign policy upon the triple alliance as supplemented by the naval entente with Great Britain, he assumed a quite unnecessarily truculent attitude toward France and initiated a tariff war which did untold harm to Italy and from which he eventually had to climb down. At home he secured the adoption of new sanitary and commercial codes and reformed the administration of justice. Forsaken by his radical friends because of his growing conservatism and dictatorial behaviour, Crispi governed with the help of the right until on Jan. 31, 1891, his tactless conduct in parliament compelled him to resign. In Dec. 1893 the impotence of Giovanni Giolitti's cabinet to restore public order, menaced by disturbances in Sicily and in Lunigiana, led to a demand that Crispi should return to power. Crispi's fierce policy of social repression and his refusal to abandon a policy of active if over-expensive imperialism in Eritrea caused a breach between him and the radical leader F. Cavallotti, who then began against him a pitiless campaign of defamation. Grave financial irregularities were brought to light in the relations between Crispi's government and the big Roman banks. Yet strong support came to him from those who wanted the suppression of socialism in Sicily and an aggressive policy against Ethiopia. The general election of 1895 gave Crispi a majority, but a year later the humiliating defeat of the Italian army at Aduwa in Ethiopia brought about his resignation. Without doubt Crispi was heavily to blame for this defeat. Furthermore, at the end of 1897 the judicial authorities applied to the chamber for permission to prosecute Crispi for embezzlement. A parliamentary commission appointed to inquire into the charges against him discovered that Crispi, while personally not dishonest, had involved himself with shady financiers and had deliberately misled the public about certain financial scandals which implicated his friends. Crispi resigned his seat in parliament and withdrew from active politics.

Following in the wake of Bismarck, Crispi had reduced the powers and independence of parliament. He had outlawed socialism and imprisoned some of the deputies of the left. His exaggerated

notions about national honour led to a much more bellicose foreign policy than Italy's economy could afford. His death at Naples, on Aug. 12, 1901, came when Giolitti was beginning a much more liberal policy both at home and abroad, but many people looked back with nostalgia to the expansive days of Crispi, and his exaggerated nationalism was to be revived in the not so distant future. Mussolini regarded him as a precursor of fascism.

An edition of Crispi's *Scritti e discorsi politici, 1847-90* appeared in 1890. This was followed by posthumous editions of his *Carteggi politici inediti* (1912), *Questioni internazionali* (1913), *Ultimi scritti e discorsi* (1913) and *Discorsi parlamentari* (1915).

(D. M. SR.)

**CRISPIN AND CRISPINIAN, SAINTS**, the patron saints of shoemakers, have a legendary history, traceable to the 8th century. It is said that they were brothers, of a noble Roman family and that they traveled to Soissons, where they supported themselves by shoemaking and made many converts. The emperor Maximian condemned them to death but they escaped from the ordeals imposed by his prefect, and at last Maximian had their heads cut off (c. 286). Their remains were buried at Soissons but were afterward moved, partly to Osnabrück and partly to the chapel of St. Lawrence in Rome. There are also relics at Fulda, and a Kentish tradition claims that their bodies were cast into the sea and floated ashore at Romney marsh. Their feast day is Oct. 25. In France, especially, it was for centuries the occasion of solemn processions and merrymaking, in which guilds of shoemakers took the chief part. In England the day acquired additional importance as the anniversary of the battle of Agincourt.

**CRISPUS CAESAR** (FLAVIUS JULIUS, or sometimes FLAVIUS VALERIUS) (d. A.D. 326), was the eldest son of Constantine the Great (q.v.) by his wife Minervina whom he divorced in 307. Educated by the Christian writer Lactantius Firmianus, he was given the title of Caesar on March 1, 317, and became titular ruler of Gaul. In the war against Licinius (q.v.) in 324 he commanded the fleet and won a decisive victory in the Hellespont, but in 326 when accompanying his father to Rome to celebrate the 20th anniversary of his accession, he was executed at Pola (mod. Pula in Yugoslavia). His stepmother Fausta was also executed shortly afterward; the story became current that she had denounced him to Constantine for attempted seduction and was herself denounced by the emperor's mother, Helena. The incident remains a mystery.

(A. H. M. J.)

**CRISTEA, MIRON** (1868-1939), first patriarch of the Rumanian Orthodox Church, who worked for unity in both church and state, was born at Toplița, Transylvania, of peasant parentage on July 20, 1868. Educated at the theological seminary at Sibiu and at Budapest, he was elected bishop of Caransebeș in 1910. In 1918 he was a member of the delegation to Bucharest that sought the union of Transylvania with Rumania, and after the union he was unanimously chosen as primate (1919), becoming metropolitan of Walachia. He brought the principles of the ecclesiastical constitution of the metropolitan A. Șaguna (d. 1873) in Transylvania to bear on his work of consolidation. From 1926 to 1930 he was one of the three regents of the country during the ill health of King Ferdinand and the interregnum before the accession of King Carol. For the last year of his life he was prime minister under the latter. He was not however a "political prelate," but lent his name and influence to the highest office in the state in an attempt to achieve political stability and unity. From his enthronement as patriarch in 1925 his influence in promoting peace and unity came to be felt among Christians outside his own country and his own church. He visited the patriarch of Constantinople and other heads of orthodox churches on a journey to Palestine in 1927, and England at the invitation of the archbishop of Canterbury in 1936. He died in Cannes on March 6, 1939. (Mr. P.)

**CRISTÓBAL**, Atlantic terminal port, town and territorial subdivision of the Panama Canal Zone, named, along with the adjacent Panamanian city of Colón, for Cristóbal Colón (Christopher Columbus). Convenient to extensive modern docks and other

maritime servicing facilities operated by the Panama Canal company are commodious anchorages in Limon bay, protected from northers by breakwaters, making Cristóbal one of the key ports of the Caribbean. Pop. (1960) 817. The Cristóbal district (1960 pop. 11,499; area 140 sq.mi.) comprises the northwest section of the Canal Zone. See PANAMA CANAL; COLÓN. (M. DuV.)

**CRITIAS** (c. 460–403 B.C.), Athenian orator, poet, philosopher and statesman, prominent at the close of the Peloponnesian War. In his youth he had been a pupil of Gorgias and Socrates, and he was accused, with Alcibiades (q.v.), of complicity in the mutilation of the Hermae in 415, for which he was imprisoned but afterward acquitted. A member of the oligarchic government of the Four Hundred in 411, he nevertheless retained his influence when the Four Hundred were overthrown and helped to secure the reinstatement of Alcibiades. When Alcibiades was discredited in 407, Critias was attacked by Cleophon and exiled. He then went to Thessaly, where he stirred up the *penestae* ("serfs") against their masters and tried to establish a democracy. Returning to Athens, he became one of the Thirty Tyrants who in 404 were appointed by the Spartans after their victory in the Peloponnesian War. He was killed in battle against Thrasybulus and the returning democrats. Critias figures in the dialogues of Plato and some fragments of elegies by him survive.

**CRITICAL POINT**, in physics, the point above or below which certain physical changes will not occur. In the study of change of state (see HEAT and THERMODYNAMICS) the properties of the substance at this point are called its critical constants, such as critical temperature, critical volume and critical pressure. At the critical point of a single substance, the properties of liquid and gas are identical and the curve of vapour pressure *v.* temperature ends at that point. In mechanics, the smallest angle which an inclined plane must make with the horizontal in order that a body resting on it should slide is called the critical angle. (See FRICTION.) In optics, critical angle refers to the angle at which rays incident to the interface between a medium of high index of refraction and one of lower index are first totally reflected internally. In an oscillating system the critical damping is the minimum amount of damping that will cause the value of its potential energy to fall to zero most rapidly without further oscillation. (See CAPACITOR; INSTRUMENTS, ELECTRICAL MEASURING; VISCOSITY.) There are other instances of use of the word critical in the sense of "limiting"; e.g., critical mass, which if exceeded will cause fissionable material to explode.

**CRITICAL POINTS.** In mathematics, a critical point of a real-valued differentiable function of a real variable is a value of the variable at which the derivative of the function is zero. Geometrically, it is a point at which the graph of the function in Cartesian co-ordinates has a horizontal tangent. Thus the function

$y(a-x)$  has a critical point at  $x = \frac{a}{2}$ , since the derivative of the function, namely,  $a-2x$ , is zero there. (See CALCULUS, DIFFERENTIAL AND INTEGRAL.)

A critical point of a real-valued differentiable function of several (say  $n$ ) real variables is a point at which all the first partial derivatives of the function are zero. Thus the function defined by  $g(x,y) = ax^2 + 2bxy + cy^2$  has a critical point at  $x = 0, y = 0$ . Geometrically, the  $n$ -dimensional plane tangent to the graph of the function in  $(n+1)$ -dimensional space is parallel to the  $n$ -dimensional plane of the independent variables. If the function in question is the potential energy of a mechanical system with velocity zero, then a critical point of the function is an equilibrium point or natural position of rest of the system.

Critical points of real-valued functions on more general kinds of spaces, where generalizations of the derivative may not be available, are defined in terms of concepts from topology.

**Maxima and Minima.**—The impetus to study critical points arose in the search for maxima and minima in problems of geometry and mechanics. A function  $f$ , of one or many real variables, has a relative maximum at  $c$  if  $f(c) \geq f(x)$  whenever  $x$  is sufficiently near  $c$ , and a relative minimum at  $c$  if  $f(c) \leq f(x)$ . The maximum or minimum is said to be "absolute" if the inequality holds for all points  $x$  at which  $f$  is defined. An absolute maximum (minimum)

is a relative maximum (minimum), but the converse need not be true. The adjective "proper" is applied to a maximum if the inequality is  $f(c) > f(x)$  when  $x$  is different from  $c$ ; the adjective is applied similarly to a minimum.

In the geometric problem of finding the rectangle of maximum area with a fixed perimeter (say  $2a$ ), the absolute maximum, with  $0 < x < a$ , of the function with value  $x(a-x)$  already considered in the first paragraph must be found.

In the method of the calculus, to be illustrated here for a differentiable function of one real variable defined on a closed interval  $a \leq x \leq b$ , the maximum or minimum of  $f$  is found to occur at  $a$  or  $b$  or at a critical point of  $f$ . This shows the logical necessity for distinguishing which critical points are relative maxima, which are relative minima, and which are neither. In the mathematical argument, suppose  $f$  has a relative maximum at  $c$  with  $a < c < b$ . The argument for a relative minimum is similar. Then  $f'(c) = 0$ , i.e.,  $c$  is a critical point, for if  $f'(c) > 0$  then on any interval about  $c$  there is a number  $x$  for which  $x > c$  and  $[f(x) - f(c)]/(x - c) > 0$ , so that  $f(c) < f(x)$ . Similarly, if  $f'(c) < 0$  there is a number  $x$  such that  $x < c$  and  $f(c) < f(x)$ . In either case, there is a contradiction to the supposed maximum.

The first general method of investigating maxima and minima seems to have been published in 1629 by Pierre de Fermat. He used the principle that in the neighbourhood of a maximum or minimum the differences of values of the function are not affected by changes in the independent variable, a method closely resembling that of the calculus. The latter was invented later in the same century by Isaac Newton and by G. W. Leibniz, but questions of distinguishing among critical points for a function of one variable were first settled by Colin Maclaurin in his *Treatise on Fluxions* (1742).

Particular cases of maxima and minima had been discussed much earlier. Euclid (*Elements*, Book iii) finds the greatest and least straight line from a point to a circle. Apollonius (*Conics*, Book v) shows that the greatest and least distances from a point to a conic section are measured along the normals (perpendiculars) from the point to the conic. Some remarkable theorems on maximum areas are attributed to Zenodorus, and are preserved by Pappus and Theon of Alexandria. They include the following:

1. Of polygons of  $n$  sides with a given perimeter, the regular polygon encloses the greatest area.
2. The circle encloses a greater area than does any polygon of the same perimeter.

Johann Bernoulli's famous problem of the brachistochrone, or curve of quickest descent of a particle from one fixed point to another under the action of gravity, was proposed in 1696 (see CURVES, SPECIAL). The function (time of descent) depends on a curve (the path) and not on one or several real variables. Of similar character is the problem, considered by Newton in 1686 in his *Principia*, of finding the shape of the surface of revolution which will meet the least resistance in moving in the direction of its axis through a resisting fluid. Such problems gave rise to another part of the theory of critical points known as the calculus of variations (q.v.).

For a function of one real variable having a continuous second derivative near  $c$ , the distinction of maximum and minimum can be made as follows. From Taylor's theorem with remainder,

$$f(x) = f(c) + \frac{1}{2} f''(\xi)(x-c)^2,$$

where  $\xi$  is an appropriate number between  $x$  and  $c$ . Suppose that  $f''(c) \neq 0$ . One then notes, for  $x$  near  $c$ ,  $f''(\xi)$  and  $f''(c)$  have the same sign, so that  $f$  has a maximum at  $c$  if  $f''(c) < 0$ , and a minimum at  $c$  if  $f''(c) > 0$ . The function  $x(a-x)$ , according to this test, has a relative maximum at  $x = a/2$ . This argument breaks down if  $f''(c) = 0$ , but resolution is sometimes possible in terms of derivatives of higher order. Graphically, this test is made by distinguishing critical points where the graph is "concave down" ("concave up") as maxima (minima).

**Index.**—The situation for a function  $f$  of  $n$  real variables ( $n \geq 1$ ) with continuous second partial derivatives near  $c$  is that  $f$  can have  $n+1$  principal kinds of critical points at  $c$ , rather than just relative maxima or minima. These critical points are distin-

guished by an invariant called the *index*. The critical point of  $f$  at  $c$  is termed "nondegenerate" if the determinant of second partial derivatives  $|f_{ij}(c)|$  is not zero. In this case, the index  $h$  of  $c$  as a critical point can be distinguished in any of the following ways:

1. The quadratic form  $Q(x) = \sum_{i,j=1}^n f_{ij}(c) x^i x^j$ , which appears in the Taylor expansion of  $f$  about  $c$ , can be reduced by a non-singular linear change of the variables  $x$  to a signed sum of squares with  $h$  negative signs.

2. The dimension of the plane of maximum dimension on which  $Q(x)$  is negative for  $x \neq 0$  is  $h$ .

3. The system  $\sum_{j=1}^n f_{ij}(c) x^j - \lambda x^i = 0$  ( $i = 1, \dots, n$ ) possesses a maximum number  $h$  of linearly independent solutions  $x$  corresponding to negative values of  $\lambda$ .

There are topological determinations of the index of a critical point which are very useful. A critical point of index  $n$  is a relative maximum, while one of index 0 is a relative minimum.

The critical point at  $x = 0, y = 0$  of the function  $g(x, y) = ax^2 + 2bxy + cy^2$  is nondegenerate if  $ac - b^2 \neq 0$ . The critical point has index 0 (is a relative minimum) if  $a > 0, ac - b^2 > 0$ ; index 1 (is a so-called saddle point) if  $ac - b^2 < 0$ ; index 2 (is a relative maximum) if  $a < 0, ac - b^2 > 0$ . Examples of these cases are furnished by  $x^2 + y^2, -x^2 + y^2, -x^2 - y^2$  respectively.

In the example of potential energy, a proper maximum of potential energy corresponds to completely unstable equilibrium, while a proper minimum corresponds to completely stable equilibrium.

**Global Theories.**—The theory of critical points thus far described is a "local" theory, concerned with the behaviour of a function near a single exceptional point. There are also "global" theories "in the large" concerned simultaneously with all the critical points of a function.

Interest in critical points grew with the work of H. Poincaré and G. D. Birkhoff in the late 19th and early 20th centuries. Two theories arose, one by L. Lusternik and L. Schnirelmann and one by M. Morse. Each is concerned, for example, with a smooth real-valued function defined on a compact manifold (see MANIFOLDS), and each is intimately related to the topological structure of the manifold. Each theory says in its own terms that topological complexity of the manifold requires every smooth real-valued function defined on the manifold to have many critical points. Inversely, each says that the existence of a simple function on a manifold limits the complexity of the manifold.

For an elementary example of the Morse theory, consider the surface of the earth, with all natural bridges broken, as the manifold (it is a topological 2-dimensional sphere), and consider altitude above sea level as the function. Then the number of peaks (relative maxima, with index 2) plus the number of pits (relative minima, with index 0) minus the number of passes (saddle points, with index 1) is equal to two, the Euler-Poincaré characteristic of the topological sphere.

The Lusternik-Schnirelmann theory for a manifold  $X$  is summarized as follows. A closed subset of  $X$  is said to be "categorical" if it can be deformed (i.e., "slid and shrunk") over  $X$  into a point. The category of  $X$  is the smallest number of categorical sets whose union (sum) is  $X$ . For example, the category of a spherical surface is 2, the two sets being, for instance, upper and lower hemispheres. The principal Lusternik-Schnirelmann theorem states that the cardinal number of critical points of any smooth real-valued function on  $X$  is at least the category of  $X$ . For example, every function on the sphere has at least two critical points. Further developments of the theory, such as those of L. Elsholts, are concerned with estimates of the category of a manifold.

The theory of Morse is more refined. Suppose that  $f$  is a smooth function on a manifold  $X$  of dimension  $n$  and that all critical points of  $f$  are nondegenerate. Let  $M_i$  denote the number of critical points of index  $i$  and let  $R_i$  denote the Betti number of  $X$  in dimension  $i$  (see TOPOLOGY, GENERAL). Then  $M_i \geq R_i$ . More precise relations, which imply these, are as follows:

$$\begin{aligned} M_0 &\geq R_0 \\ M_0 - M_1 &\geq R_0 - R_1 \\ M_0 - M_1 + M_2 &\geq R_0 - R_1 + R_2 \end{aligned}$$

$$M_0 - M_1 + \dots + (-1)^n M_n = R_0 - R_1 + \dots + (-1)^n R_n.$$

Further developments of the Morse theory have included group-theoretic formulations such as that by R. Deheuvels, and strengthened inequalities by E. Pitcher which involve torsion coefficients as well as Betti numbers.

Each of the theories of critical points of a function on a manifold admits an extension to the extremals of an integral in the calculus of variations. In the latter field the Morse theory achieves great power.

**CRITICISM**, reasoned and systematic discussion of the arts explaining or evaluating their techniques and products. It is thus distinct from aesthetic perception, reaction or appreciation, with all of which it is often confounded. This article is restricted to the criticism of literature, which has engaged the efforts of more genius and presents in its history both greater variety and greater continuity than that of any other art. See also DRAMATIC CRITICISM.

**The Greeks.**—While the Sophists had analyzed tropes and figures, and while criticism was practised doubtless even earlier, Plato (c. 428-c. 348 B.C.) was the first theoretical critic. In his philosophy, all arts and sciences are as inferior to dialectic as their objects are to the "eternal ideas"; hence he treats poetry and rhetoric only generally, and in terms of criteria not of art but of ethics, politics and metaphysics. His view of knowledge as reminiscence implies that statements found in the Platonic dialogues are not to be taken as doctrines but as recollections of a truth once known, stimulated in the forgetful soul by dialectic; recapturing always incomplete, and relative to the stage of advancement both of the soul and the argument. Later critics, however, took his remarks on poetic inspiration and his strictures on poetry as rigid doctrine.

Plato applied the term "imitation" both to poetry and to the natural world, as copying the "Ideas"; Aristotle (384-322 B.C.) used it to distinguish the mimetic aspects of art. Plato, pursuing likeness, uses one method to find the one principle of all knowledge; Aristotle, pursuing differences, establishes sciences diverse in subject matters, principles and methods. In his view, thus, poetics is a science of the making of poetry considered as an imitative art; hence in *Poetics*, book i, he distinguishes the kinds of mimetic poetry according to the means (ch. 1), object (ch. 2), manner (ch. 3) and effect of imitation (ch. 4-5). Gathering these elements into a definition of tragedy (ch. 6) as an artistic whole, he reasons from it as from a principle to find the number, nature, relative importance and proper construction of the parts of tragedy: plot, character, thought, diction, music and spectacle (ch. 7-22). Epic he treats in terms of its differences from tragedy (ch. 23 ff.). Book ii of the *Poetics*, on comedy, is lost. His *Rhetoric* analyzes the three means of inducing conviction—character, emotion and proof—as they function diversely in political, legal and display oratory.

**The Alexandrian Age.**—In the Alexandrian age of philology and science (300-146 B.C.), poetics and rhetoric were severed from philosophy and pursued as autonomous studies or as departments of grammar. After the disappearance of the Aristotelian texts in 287 B.C., the distinction between mimetic and didactic poetry was lost; much looser discussion ensued of the respective roles in poetry, of nature and art, subject and style, instruction and pleasure. The decline of tragedy, the metamorphosis of epic into learned mimicry of Homer or into didactic treatises, the rise of romance and the growing preference for short forms such as elegy and idyll altered the body of literature on which criticism was exerted; such works as the *Homeric Problems* of Zeno set a fashion of allegory hunting which turned criticism itself into grammatical exegesis, and plot and character were treated as symbols. Significantly, the chief critics are, like Callimachus and Aristarchus, grammarians, editors, compilers; and Dionysius Thrax (fl. 100 B.C.), whose *Art of Grammar* was to have vast influence, lays claim

to poetic criticism as the highest office of grammar.

**Roman Rhetoric.**—Roman conquest of Greece in 146 B.C. shifted the centre of learning from Alexandria to Rome, and the high importance of persuasion in republican life raised rhetoric from a technique of proofs and styles to a master science of which poetry, history and even philosophy were offshoots. Cicero (106–43 B.C.), whose works reflect this change in status, bases his theory on the belief that oratory had founded and developed civilization. While his technical remarks draw heavily from Aristotle, whose works had been recovered, his conception of the ideal orator owes much to the Platonic conception of the dialectician. For Cicero as for Quintilian, whose *Institutio oratoria* (A.D. 93) prescribes the whole education of the orator, rhetoric is broadly humanistic, with rules suggestive rather than rigid. Elegancies of style were not, however, neglected by either, and were the special study of Dionysius of Halicarnassus, Demetrius and “Longinus”; indeed, the latter’s *On the Sublime* treats of a single quality of style—sublimity—effecting transport rather than persuasion. Under the empire, rhetoric’s usefulness diminished and it declined into preciosity and sophistry, as Cornelius Tacitus and others testify.

**Medieval.**—The early church, antiliterary and suspicious of things pagan, wrought not so much a rejection as a transformation of classical literature. Although Plato’s censures of poetry were rephrased by Tertullian, Augustine and Jerome, allegorical interpretation soon found Christian truth contained in works that, read literally, seemed pagan fiction; and poetry, as didactic allegory—perhaps its chief role during the middle ages—easily entered the service of theology. With poetry a versified rhetoric of indirect statement, criticism became the exegesis of its enigmas; and the passion for riddle reading, together with the loss of nearly all ancient criticism save the *De inventione* of Cicero and the *Rhetorica ad herennium* attributed to Cornificius, confined medieval poetic to a discussion of tropes and figures; and this conception of criticism underlies the Vergilian commentaries of Macrobius, Servius and Fulgentius, the 12th- and 13th-century *poetriae* of Matthieu de Vendôme, Geoffroi de Vinsauf and John of Garland, and the critical observations even of Dante Alighieri.

**The Renaissance.**—The way was prepared for Renaissance criticism by Laurentius Valla, Politian and other Italian humanists of the 14th and 15th centuries. Recovery of such works of classical theory as Quintilian’s (1416), Cicero’s *Brutus* (1421) and *Orator* (1422) and the translation of Aristotle’s *Poetics* by Giorgio Valla (1498) opened new ranges of method; the restoration of the great literary monuments, both Latin and Greek, afforded new models for recommendation. Moreover, literature itself had undergone subtle development; out of popular origins had sprung new forms such as the chivalric romance, the fabliau and the *novella*; drama and epic had revived; modern languages had all but supplanted Latin as the medium of serious literary art. With all this change came the problems of change, coupled with newly inherited unsettled questions of the past, to stimulate the efforts of Marco Vida, G. G. Trissino, A. S. Minturno, J. C. Scaliger and L. Castelvetro in Italy; Thomas Sibilet, Joachim du Bellay, Pierre Ronsard, Jean de la Taille and Jean Vauquelin de la Fresnaye in France; Roger Ascham, Richard Willes, George Gascoigne, Sir Philip Sidney, William Webbe and George Puttenham in England.

**Neoclassicism.**—Thus arose a neoclassicism based upon Roman rhetoricians, Horace and Aristotle as interpreted by Italians of the 16th century and by Dutch and Germans of the 17th (Daniel Heinsius, Justus Lipsius, J. Pontanus). In the fascination with Aristotle’s doctrine, his method, capable though it was of extension with the growth of literature, went unobserved; though 17th-century critics quickly discarded the medieval conception of poetry as allegory, the mimetic function was never fully disengaged from the didactic, even by Ben Jonson and John Dryden; and such rigid formulations as the *Art poétique* of Nicolas Boileau (1674), treating poetic kinds as natural and permanent species, could neither constrain nor serve literary development; indeed, their final effect was to provoke attack on the theory of fixed species and criteria, by David Hume, Samuel Johnson, Johann Friedrich Schiller and others.

**Criticism and Aesthetics.**—With specific technical criticism

discredited, criticism became increasingly qualitative, discussing poetic qualities rather than kinds, characteristics of parts rather than the structure of the whole. The rise of the “new science” of aesthetics (Alexander Baumgarten, 1750), the growing doctrines of taste and genius, the emphasis on imagination in art—begun by Francis Bacon and continued by Edmund Burke, Gotthold Lessing, Sir Joshua Reynolds, Kant and S. T. Coleridge—and the rise of romantic literature all co-operated to exorcise at last the spectre of didacticism; but criticism had grown ever more general, and 19th-century critical discussion, save for the particular insights of men such as Coleridge, turned on such generalities as the nature of poetry, poet, imagination, fancy, critic, etc. (Charles Ste. Beuve, Matthew Arnold, John Stuart Mill) and eventuated in impressionism (Walter Pater, Anatole France) or intuitionism (Benedetto Croce). (See AESTHETICS.)

**The 20th Century.**—As even these broad generalities came under attack, 20th-century critics strove to find new bases, drawing them from such sciences as psychology, anthropology, semantics and political theory. At mid-century, while the political, social and psychological aspects of literature had been somewhat clarified, aesthetic criticism was still qualitative, even in the hands of T. S. Eliot, and still centred, as in the Alexandrian age, on medium (I. A. Richards, William Empson, Cleanth Brooks) or on subject matter (Maude Bodkin); and the vogue of symbolism, fostered by the success of W. B. Yeats and Eliot, threatened to reduce poetry once more to didactic allegory and its criticism to grammatical exegesis.

As the foregoing survey shows, criticism does not in its history exhibit a steady logical development of principles laid down in antiquity, nor indeed the fortunes of a continued debate. It has strict unity neither of subject matter, method nor aim. Its continuity lies in the attempts of men to deal with a changing body of literature in terms of changing aspects of concern, for changing aims, through methods dictated by such concerns and aims and hence altering with them. Its character is, furthermore, affected by the circumstances of a given time: the state of a language or literature, the body of available doctrines, methods and models, the interpretation and application of these. So viewed, the history of criticism affords support neither for the skeptic who would see in it a prolonged contest, futile because the questions involved are unanswerable, nor for the dogmatist who would find in it a gradual progress toward his dogma. Criticism presents neither a single fully developed theory of literature nor a chaos of contradictions. It has had, like other departments of knowledge, its share of confusion and error caused, in its case, largely by shifts in the meanings of terms, the separation of doctrines from the methods which developed them and misapplications of method. Yet it is a fact often overlooked that criticism has usually solved the problems posed to it in each period, although the problems are not always posed and resolved to the satisfaction of later generations.

The subject matter of the arts is necessarily inexact, and hence not amenable to the methods of exact science; but the failure to provide, even by the 20th century, full and sound theories of rhetoric and poetics is not due to inexactness in the subject. It is due rather to certain human tendencies: the tendency to regard art as finite and completely developed, whereas, like all that depends upon invention, its capacity for development is infinite; the tendency to forget that sound theoretical bases are not nullified by the emergence of new forms and devices, or, conversely, to forget that theory must expand with art; the tendency to ignore differences of kind and function (e.g., to treat mimetic poetry as didactic); the tendency to confuse validity with universality, and hence to insist that a rule must be universally or absolutely true because it is true specifically and conditionally, or, conversely, to insist that a rule is utterly false because it is not true universally or absolutely. These tendencies, repeatedly resulting both in the premature framing and the premature rejection of theories, are the chief hindrances to critical progress, and are likely still to prevent our full realization of the vast fund of knowledge achieved by critical discussion over the centuries. (E. J. O.; X.)

**The “New Criticism.”**—In 1941 John Crowe Ransom coined the term “new criticism” for what is in certain essential respects a

return to the Renaissance rhetoricians' principle that a poem is an arrangement of words, to be apprehended in their interaction. It is not that plot, character and theme do not exist, but that for the reader of the work only the words on the page make them exist.

The particularity of insight required by this re-emphasis on the specific assisted in the final separation of the critic from the literary theorist. Most of T. S. Eliot's *Selected Essays, 1917-1932*, originally written as reviews, differed from adjacent reviews by the rigour with which details were examined and the economy with which quotations were juxtaposed to imply much exact comment. "Comparison and analysis," Eliot wrote in 1923, setting in circulation a formula borrowed from Remy de Gourmont, "are the chief tools of the critic."

In Eliot's work the "scale of values" with which critics are often credited is conceived to be not like the marks on a ruler, i.e., a set of graduations achieved in isolation from anything to be measured, but like the scale of C, i.e., a group of sounds so arranged as to clarify their relations. Ezra Pound's *ABC of Reading* (1934) expounds the view that critical skill is nourished chiefly by knowing what has been done in the arts, and consists principally in the ability to see what is before one. "I should like if possible," wrote Pound, "to sharpen your perceptions, after which your taste can take care of itself." Eliot's essay on Philip Massinger makes his "decadence" concrete in specific and demonstrable terms. Similarly, F. R. Leavis' *Revaluation* (1936) outlines several chapters of English literary history entirely in terms of particular instances, related and affiliated.

Naturally, such work allies itself with pedagogy: with sharpening the reader's ability to read. I. A. Richards' *Practical Criticism* (1929) demonstrated conclusively that many people professing interest in poetry have only the most rudimentary ability to apprehend it, and are arrested in the extremely complex business of reading by various partial satisfactions which Richards was able to codify. His pupil William Empson demonstrated in *Seven Types of Ambiguity* (1930) how subtle and evanescent effects can frequently be dissociated into multiple meanings that have been instantaneously apprehended and fused. In Empson's wake a great deal of ingenious exegesis, often interesting but not always relevant, was manufactured on behalf of a wide variety of poets.

The new criticism, despite its Alexandrian tendencies, gave new definition to the scope of criticism and achieved the most varied body of critical writing since the 18th century. (Hh. K.)

**CRITIUS AND NESIOTES** (fl. late 5th century B.C.), Greek sculptors of the time of the Persian wars. When Xerxes carried away to Persia the statues of Harmodius and Aristogiton made by Antenor, Critius and Nesiotes were commissioned to replace them. By the help of coins, vases, reliefs and fragments at Naples, now correctly restored, and Rome, it has been possible to identify Roman copies of the Tyrannicides of Critius; and to them well apply the words in which Lucian describes the works of Critius and Nesiotes, "closely knit and sinewy, and hard and severe in outline." Critius also made a statue of the armed runner Epicharinus. Perhaps the finest copy of the Tyrannicides is that in the Museo Nazionale in Naples; a reconstructed statue of Aristogiton is in the Museo dei Conservatori in Rome.

**CRITOLAUS** (2nd century B.C.), Greek philosopher, was born at Phaselis in Lycia. He studied under Ariston of Ceos and may have been his direct successor as head of the Peripatetic school; if so, his headship was of long duration, but the date of his death is not known. He was one of the three ambassadors, representing different schools of philosophy, whom the Athenians sent to Rome in 156-155 B.C. to protest against a fine of 500 talents imposed on their city. It was his policy to restore to favour, where possible, the original doctrine of his school; thus, he defended against the Stoics the belief in the eternity of the world and of the human race, using for this purpose arguments similar to those of Aristotle and Theophrastus and maintaining the belief in ether. But in ethics he went some way to meet the Stoic views; for instance, he defined the highest good in phraseology partly taken from Zeno, declared pleasure to be an evil and held that the goods of the soul entirely outweigh the goods of the body and those of external fortune.

See E. Zeller, *Aristotle and the Earlier Peripatetics*, Eng. trans., vol. II, pp. 479 ff. (1897); H. von Arnim, "Kritolaos," in Pauly-Wissowa, *Realencyclopädie*, vol. XI (1922); and K. O. Brink, "Peripatos," *ibid.* supp. vol. VII (1940). (D. J. A.)

**CRITTENDEN, JOHN JORDAN** (1787-1863), U.S. statesman best known for his efforts at compromise on the eve of the American Civil War. Crittenden was born near Versailles, Ky., on Sept. 10, 1787. After attending school in Jessamine county he studied law and in 1807 graduated from William and Mary college. He then opened law practice in Logan county and in 1809 was appointed territorial attorney general in Illinois. During the War of 1812, after he had returned to his native state, he combined military service with membership in the Kentucky legislature. His service in the U.S. senate began in 1817 and continued at irregular intervals until his death in 1863.

Crittenden supported his fellow Kentuckian, Henry Clay, for the presidency in 1824 and continued to have great respect for Clay and his policies for the rest of his life. With Clay, he opposed the financial policies of Andrew Jackson and of Martin Van Buren. He campaigned for William Henry Harrison in 1840 and resigned from the senate to become U.S. attorney general upon Harrison's election. Along with other Whigs in the cabinet, he resigned in Sept. 1841 in protest against the attitude toward the Bank of the United States taken by John Tyler, who had become president upon the death of Harrison.

As a "Conscience Whig," Crittenden opposed the annexation of Texas, opposed taking a belligerent attitude toward Great Britain over the Oregon boundary and refused to give more than lukewarm support to the Mexican War. In 1848 he was elected governor of Kentucky. In spite of his lifelong friendship with Clay, he supported Zachary Taylor for president in 1848, for he was convinced that Clay could not win election. This led to a misunderstanding between Clay and Crittenden that lasted until just before Clay's death in 1852.

Crittenden opposed the Kansas-Nebraska act of 1854 in congress and when this issue led to the breakup of the Whig party, he joined the American, or Know-Nothing party in 1856. Later he joined the Constitutional Union party, campaigning for John Bell and Edward Everett in 1860.

After Lincoln's election, he introduced his "Crittenden resolutions" in Dec. 1860. These proposed that the Missouri Compromise (*q.v.*) line be restored and continued to California, that slavery be guaranteed indefinitely in the District of Columbia, and that slaveholders be reimbursed for runaway slaves not returned. The compromise effort was eventually defeated by Lincoln's strong stand against any extension of slavery into the territories, and by radical Republican leadership in congress.

Early in 1861, Crittenden returned to Kentucky to try to save his state for the Union. In March, and again in May, he demanded that Kentucky remain in the Union, although he urged its neutrality in the war. On May 27 he acted as chairman of the Frankfort convention of border state leaders, which asked the South to recon-

sider its position on secession. He then returned to congress, this time to the house of representatives. He opposed the confiscation acts, the Emancipation Proclamation and the military regime in Kentucky. In the meantime, one of his sons, Thomas L. Crittenden, had become a major general in the Union army; another, George B. Crittenden, a major general in the army of the Confederacy. Crittenden was preparing to run for re-election to congress at the time of his death in Frankfort, Ky., July 26, 1863.

**CRIVELLI, CARLO** (c. 1430/35–c. 1493/95), one of the most striking figures of 15th-century Venetian painting, was born in Venice but left that city after being sentenced to prison and thereafter worked chiefly in the March of Ancona, and especially in and near Ascoli. He was probably an offspring of the Vivarini school and was influenced by Squarcione's academy at Padua. He signed as "Carolus Crivellus Venetus"; from 1490 he added "Miles," having been then knighted (*Cavaliere*) by Ferdinand II of Naples. Among his earliest works are the "Madonna" in the Verona museum and an altarpiece at the Municipio of Mazza Fermana (1468). The National gallery in London has fine examples of Crivelli; in Berlin is a "Madonna and Saints" (1491); in the Vatican gallery a "Pietà"; and the Brera of Milan contains several examples, among which is his masterpiece of later years, "The Coronation of the Virgin" (1493).

"PIETÀ" BY CARLO CRIVELLI; c. 1485. IN THE VATICAN GALLERY, ROME

Crivelli's works are of marked individuality—hard in form, definite in outline; stern, forceful, energetic, but often glowing with colour and sumptuous, fantastic ornamentation. He died between 1493 and 1495. It is surmised that Carlo was of the same family as the painters Jacopo and Vittorio Crivelli. Pietro Alamanni was his pupil.

See Bernard Berenson, *The Venetian Painters of the Renaissance* (1899).

**CRNA GORA:** see MONTENEGRO.

**CROAGH PATRICK** (CRUACH PHADRAIG, "the rick of St. Patrick"), a splendid quartzite peak, lies to the southwest of Westport at the head of Clew bay in Mayo, Republic of Ireland. It rises in a sharp pyramid to 2,510 ft. from a plateau 800–1,100 ft. high in which stands over a coastal lowland nearly a mile wide. From the top can be seen the head of Clew bay, varied by scores of drumlins, with the hills of north Mayo beyond. The mountain, having some archaeological remains, has acquired a mass of legend. It is said to have been visited by St. Patrick who, according to one report, here began his Irish ministry and banished snakes from the country with his bell. He blessed Connemara but, thinking it bleak, he went on elsewhere. In modern times, Croagh Patrick has become the scene of an annual pilgrimage, the last Sunday in July (Garland Sunday), in which thousands of people take part. Starting from Murrisk, 5 mi. W. of Westport, many go up the mountain barefoot, and the course is marked by the Stations of the Cross and by statues; on the summit is a tiny chapel made from cement carried up in bags by pilgrims.

(T. W. FR.)

**CROATIA** (HRVATSKA), a country of southeastern Europe, politically organized since 1946 as one of the six republics of federal

Yugoslavia. Comprising as it does the territories of Dalmatia and most of Istria (Austrian provinces before World War I) as well as the formerly Hungarian Croatia-Slavonia, it extends in a crescent from the fertile plain between the Danube, Drava and Sava rivers in the east to the Gulf of Venice in the west and then southward along the Adriatic coast to the frontier of Montenegro. It is bounded on the north by Slovenia and by Hungary and on the east by Serbia; within the crescent, its frontier marches with Bosnia-Herzegovina, which moreover as a narrow corridor to the Adriatic crosses Croatian territory north of the point where it joins Montenegro. Area 21,829 sq.mi. Population (1961) 4,148,122.

The people (see YUGOSLAVIA) are mainly Croats and Roman Catholics. Their position has exposed their social life and culture to influences from central Europe, from the Balkans and from the Mediterranean, Italian influences being prevalent in Dalmatia and Istria. Zagreb is the capital, Rijeka (Fiume) the chief port. Other major ports are Zadar, Sibenik, Split and Dubrovnik.

Croatia-Slavonia's economy used to be based primarily on agriculture and cattle breeding. After World War II, however, industry made rapid progress. While the timber industry maintained its earlier importance, the expansion of light industry and the discovery of rich oil fields considerably changed the character of the country. The peasant population, which amounted to 82% in 1919, numbered 52% in 1960. The hardy people of the mountainous littoral of Istria and Dalmatia are traditionally either wine and olive growers or fishermen and seafarers, but there too more attention was paid after World War II to the industrial exploitation of natural resources (hydraulic power, coal and bauxite) as well as to shipbuilding and to tourism (especially in Dalmatia).

## HISTORY

The Croats (*Chrobati*, *Hrvati*) migrated in the 6th century A.D. from White Croatia, a region which is now Ukraine between the Southern Bug and Dnieper rivers, to the lower Danube valley. Thence they continued toward the Adriatic, where they conquered the Roman stronghold Salona in 614. After settling in the former Roman provinces of Pannonia and Dalmatia and liberating themselves from the warlike Avars, they began to develop independently. The farming Croats continued their former way of life under their *zupani* or tribal chiefs, who performed administrative, judicial and military functions, undisturbed by the municipal life surviving in the old Roman colonies in coastal towns under Byzantine protection. In the 7th century, when they were converted to Christianity, a bishopric for all Croatian lands was established at Nin (north of Zadar). Shortly afterward they received the privilege of using their national language in church services—a ritual right still preserved in some coastal dioceses. Under pressure from the neighbouring Frankish and Byzantine empires, the tribal organization of the Croats gradually gave way to larger units, and in the 8th century there existed two Croatian duchies, one in Dalmatia along the Adriatic coast, the other in Pannonia. After the Frankish-Byzantine peace of 812, Pannonian Croatia became a part of the Frankish empire and the Dalmatian duchy recognized nominal Byzantine supremacy. In the middle of the 9th century the Pannonian Croats liberated themselves and joined the Dalmatian duchy, which also shook off foreign domination. By 880 Branislav (879–892) became the first independent *dux Croatorum*.

**The Croatian Kingdom.**—One of Branislav's successors, Tomislav, annexed the Dalmatian cities and in 925 received the royal crown from Pope John X. Tomislav and his heirs made strenuous efforts to defend their kingdom both from the short-lived Bulgarian empire in Pannonia and from Venice, which was spreading its power along the Dalmatian coast. The Byzantines helped Stjepan Držislav (969–997) to liberate the coastal towns from Venice but succeeded in re-establishing their own influence on the Adriatic. Petar Kresimir (1058–74) altered this situation. He broke off relations with Byzantium, strengthened Croatia's ties with the papacy and enlarged the state boundaries. Croatia then reached the peak of its power. It spread southward along the Adriatic coast from the river Rasa in Istria to the rivers Tara and Piva in Montenegro, eastward to the Drina and northward to the Drava and to the Danube. Nevertheless, Kresimir's policy divided

the nation into a Latin group which upheld the king and a national group which enjoyed popular support in opposing the king's policy. This division became fatal during the reign of Dimitrije Zvonimir (1076-89), who was crowned in Split by the legate of Pope Gregory VII. Invited by the pope to participate in a war against the Seljuk Turks, Zvonimir convened a great assembly to win his subjects over to this campaign. The people accused him of being a papal vassal and killed him. Anarchy and civil war followed, and with it the decline of the Croatian kingdom. The Byzantines again secured their position in Dalmatia, and in 1091 Laszlo I of Hungary occupied most of Pannonian Croatia, claiming the Croatian throne as Zvonimir's brother-in-law.

Laszlo's deputy Almos founded a bishopric at Zagreb in 1094, and this soon became the centre of ecclesiastical power. Petar Svacic, who resided at Knin, was proclaimed king by the Dalmatian Croats in 1093, but the pope considered him a rebel and invited King Kalman of Hungary to unseat him. Kalman invaded Croatia, and Svacic fell in 1097 in the defense of his country. He was the last king of Croat blood. After prolonged warfare Kalman negotiated a treaty, the so-called *pacta conventa*, with the Croats' representatives. They elected him their king and he pledged himself to respect Croatian state rights. In his coronation sermon in Biograd (near Zadar) in 1102 Kalman swore that Croatia and Hungary would remain two independent kingdoms under St. Stephen's crown and that the king would personify this union. Only Bosnia, a part of the Croatian kingdom, refused to submit to a foreign monarch.

**Union With Hungary.**—Henceforth for eight centuries Croatia was connected with Hungary. Their relationship often changed. Some kings attempted to abolish the personal union and to integrate Croatia into Hungary, while on other occasions the Croats selected their kings independently of the Hungarians. Several Croatian *bans* or viceroys, members of the feudal nobility, conducted semi-independent policies, particularly on the Adriatic coast, or became hereditary rulers in Bosnia. The reign of the Hungarian national dynasty, the Arpads, was instrumental in introducing feudalism on a western pattern in Croatia. In 1301, on the extinction of the Arpads, the Croats crowned Charles Robert of Anjou-Naples as their king at Zagreb. This broke the personal union with Hungary until the Hungarians also accepted him in 1310 (as Charles I of Hungary). After the death of Louis I of Hungary and Croatia and several years of dynastic conflicts, the Croats in 1403 crowned the Neapolitan prince Ladislav at Zadar. It was to secure financial means to fight Sigismund, his rival in Hungary and later Holy Roman emperor, that Ladislav sold Dalmatia (*q.v.*) to Venice, which ruled it for the next four centuries. The appearance of the Turks in the Balkans in the 15th century imposed a period of hard struggles on the Croats. Bosnia, which under Tvrtko Kotromanic (1353-91) became an independent kingdom, fell to the Turks in 1463. The battle at Krbavsko Polje (1493), where most of Croat forces perished, was followed by the defeat of Louis II of Hungary and Croatia at Mohacs (1526), after which the greater part of Pannonian Croatia shared the fate of central Hungary and fell under Turkish domination. The once wide Croatian kingdom was reduced to *reliquiae reliquiarum* ("relics of relics"). Zagreb became a border fortress, and henceforth the Croatian capital.

**The Habsburg Period.**—In preference to the Hungarian candidate John Zapolya, the Croatian estates sitting at Cetin on Jan. 1, 1527, elected the Habsburg Ferdinand of Austria (the future Holy Roman emperor Ferdinand I) as king. They confirmed the succession to him and his heirs in return for the promise of common defense and his respect of their prerogatives. For the next century Croatia was a bastion defending central Europe from the Turks. The Vojna Krajina (Ger. *Militärgrenze*), a military frontier zone on Croatian territory, was formed in 1578. As this zone was subject directly to the emperor in Vienna, it meant a further loss for the Croats.

Turkish invasion instigated a partial change in the ethnic aspect of Croatian lands. Large numbers of Croats abandoned their homes and moved northward seeking safety, some even going out of Croatia altogether into Austria. In partly depopulated areas the rulers settled German and Hungarian soldiers and craftsmen or granted certain privileges to the Serbs who escaped from the Bal-

kans and took refuge in the Vojna Krajina to become defenders of the Habsburg empire. As the Turks were driven back in the 17th century the Habsburgs revealed absolutist tendencies. They attempted to curtail the state rights and autonomy of Croatia and Hungary and to reduce them to mere provinces under centralized royal power. The Croatian and Hungarian nobility jointly resisted such encroachments on their prerogatives and finally plotted an anti-Habsburg movement aiming at the political independence of their countries. The plot failed. Its Croatian leaders, Count Petar Zrinski (whose grandfather had been the heroic defender of Sziget against Sultan Suleiman in 1566) and Duke Krsto Frankopan, were beheaded at Wiener Neustadt in 1671 and their estates distributed among alien nobility. This meant a further invasion of Croatia by foreigners.

In 1712 the Croatian diet accepted the Pragmatic sanction declaring that in default of male heirs the succession to the throne could be assumed by a Habsburg princess. The Hungarians accepted it 12 years later, after receiving imperial guarantees of the indivisibility of the lands of St. Stephen's crown. Because of this stipulation the Hungarians considered Croatia as annexed territory while the Croats claimed that they were an associated kingdom. This controversy upset the old relationship between Croatia and Hungary.

**The Rise of Croatian Nationalism.**—After the annexation of Rijeka (Fiume) to the crown of St. Stephen in the 1770s, the Hungarians began trying to give their language official status in Croatia. This provoked a forceful reaction and a sudden awakening of the Croats' national consciousness. The French Revolutionary Wars and the Napoleonic establishment of the Illyrian provinces of the French empire, which after 1806 included Dalmatia and a part of Croatia south of the Sava, fomented national sentiments. Beside the progressive measures of the period, particularly in economy and education, the beneficent administration made possible the appearance of the first newspaper in the Croatian language.

After the fall of Napoleon relations between Croats and Hungarians soon became critical. To strengthen their opposition to the germanizing policy of the Habsburgs, the Hungarian revolutionaries strove to consolidate the lands of St. Stephen's crown and to establish a Magyar national state from the Carpathians to the Adriatic. The Croats refused to renounce their nationality or to accept any violation of their autonomy in the national interest of the Hungarians. In open defiance of Hungarian claims, Count Juraj Draskovic proposed in 1832 to the Hungarian parliament a national and cultural program for Croatia. It expressed the ideas of the "Illyrian movement," organized by Ljudevit Gaj, which aimed at the union of all South Slavs (Yugoslavs) within the Habsburg federation. Nevertheless, in April 1848, the Hungarian parliament approved laws which radically affected Croatia's autonomous position. Instigated by the *bán*, Josip Jelacic, in Sept. 1848, the Croatian diet rejected the Hungarian laws and accepted a series of national laws of a revolutionary character. It broke off ties with Hungary and affirmed the independent position of Croatia including Rijeka and the Vojna Krajina. It also abolished serfdom and proclaimed the equality of all citizens. After abortive attempts to compromise with the Hungarians Jelacic led his troops into Hungary. His success was of little avail for Croatian rights and interests. In defending the Croats from Magyar nationalism he saved the Habsburg empire from the Hungarian revolt.

After 13 years of imperial absolutism and political lethargy a reorganization of the Habsburg empire was planned by the centralist patent of Feb. 26, 1861. The Croatian diet, claiming that the events of 1848 dissolved their legal bonds with Hungary, protested against the patent and demanded a federalist constitution. Thereupon the diet was dissolved in 1865 and no new diet was elected. In 1867, the crown and the Hungarians reached their "Compromise" (*Ausgleich*), whereby the Germans and the Hungarians were established jointly as the dominant nations of the new dual monarchy of Austria and Hungary, Croatia having been assigned to the Hungarian part. In April the emperor Francis Joseph convoked a new diet inviting it to send a delegation to Budapest to attend his crowning as king of Hungary. The diet refused and in May was dissolved again. In 1868, however, the Croats and the

Hungarians concluded a compromise of their own, the *nagodba*, whereby the triune kingdom of Croatia, Slavonia and Dalmatia was recognized as a distinct political nation with its own territory, though still part of the Hungarian as opposed to the Austrian unit. In spite of this, Dalmatia was not united with Croatia-Slavonia and remained an Austrian province. Croatia obtained autonomy in home affairs, education, judiciary and later in agriculture. The local government was headed by a *ban* proposed to the emperor by Budapest but responsible to the Croatian diet. The diet was represented in the common parliament in Budapest. The Croatian language was given official status throughout the land. The *nagodba* was accepted by a corruptly elected diet and remained valid until 1918.

Croatian opposition to *nagodba* expressed itself in two different movements, both initially inefficient because of the very restricted electoral right. Josip Strossmayer, bishop of Djakovo and leader of the National party, developed the Illyrian movement into a cultural South Slav community under Croatian leadership, but lacked dynamism to make it a program of political action. The rebellious Ante Starcevic's program called for resistance to Austrian and Hungarian interference with Croatian national interests and aspired to self-determination and ultimate freedom of the Croats. His Party of Rights requested the union of all Croatian provinces of the empire, including Dalmatia and Bosnia-Herzegovina. Starcevic's program instilled a fighting spirit into Croatian politics. Hungary tried to restrain Croatian opposition by appointing Count Karoly Khuen-Héderváry as *ban* in 1883, but 20 years of his policy of magyarization only exacerbated Croatian-Hungarian relations. The year 1903 was a turning point in Croatian politics. The political leaders in all Croatian provinces became intensively active, seeking to concentrate their forces and to organize them into new parties and initiating co-operation with the Serbs in Croatia. A program of action—the "Rijeka resolution"—was proposed by Ante Trumbic (q.v.) and Frano Supilo in 1905 and accepted by many Croatian politicians and by Serbian representatives in Croatia. In 1906 the Croatian-Serbian coalition won a sweeping electoral victory and henceforth became an important political factor. Another achievement of decisive consequence was the organization of the Croatian Peasant party by the brothers Ante and Stjepan Radic. Realistic and aware of social problems, they stimulated an interest in politics among the peasants.

The governing circles in Budapest and Vienna refused to palliate this seething discontent with timely concessions. The Hungarians intensified their oppression either by appointing in Croatia underlings subservient to Budapest or instigating persecutions and trials. In 1907 the *ban*, Levin Rauch, having failed to secure a majority, suspended the diet. In 1909 the leaders of the Croatian-Serbian coalition having been accused of treason, brought an action for libel against the historian Heinrich Friedjung in Vienna, in which it was shown that the documents on which the charges of treason were based had been forged and supplied to Friedjung by Austro-Hungarian officials. In 1912 Rauch's successor Nikola Tomasic suspended the constitution. This was followed by the appointment of a royal commissar, whose dictatorial methods only cemented Croatian-Serbian solidarity in the empire.

Some influential court and military circles in Austria expected to counteract Croatian political evolution by proposing trialism instead of dualism. By trialism all the South Slav lands of the empire would have been united under the name and leadership of Croatia, which would have had status equal to that of Austria or Hungary. This failed because of Hungarian opposition. Most Croats saw by then that within the Habsburg empire there could be no satisfactory solution of their problem.

**The Yugoslav Union.**—Serbian and Montenegrin victories over the Turks in the Balkan Wars of 1912–13 encouraged the Croats to envisage freedom in an independent Yugoslav union that would include Serbia and Montenegro, but in 1914, when the archduke Francis Ferdinand was assassinated at Sarajevo, relations between the Croats and the Hungarians appeared to be calm, thanks to the policy of compromise pursued by the Croatian-Serbian coalition, which in 1913 had become the government party in Croatia. The unsettled problem of Croatia's status, however, prepared the

way for Yugoslav revolutionary action. With the outbreak of World War I the Austro-Hungarian authorities introduced measures of extreme severity throughout their South Slav provinces.

In his coronation speech in 1916 the emperor Charles recognized Croatian integrity in relation to Hungary, thereby establishing the equality of both countries under St. Stephen's crown. Then the Yugoslav club in the Vienna parliament, in May 1917, demanded the union of all the South Slav provinces under the Habsburg crown. Among the Croats, meanwhile, the movement for a Yugoslav union was gaining strength, with Starcevic's Party of Rights as its protagonist. The centre of Croatian politics, however, was the Yugoslav committee in Paris and London. This had been organized in 1915 by a group of Croatian, Serbian and Slovene politicians from the empire, led by Trumbic. Its program was the complete separation of the Croats, Serbs and Slovenes from the Habsburg empire and their union with independent Serbia. The committee became one of the decisive factors in the settlement of the Croatian problem. On July 20, 1917, Trumbic and Nikola Pasic, the Serbian prime minister, signed the declaration of Corfu which established the basic principles of a future Yugoslav state. In March 1918, at their meeting in Zagreb, the South Slav political leaders of the Habsburg empire declared themselves openly in favour of an independent Croatian-Serbian-Slovene state, thus approving the Corfu declaration. On Oct. 29, 1918, the Croatian diet broke off all ties with Hungary and Austria and proclaimed an independent Croatia which entered into a state union with other South Slav provinces of the empire, to be governed by a national council. On the request of council's emissaries, on Dec. 1, 1918, the Serbian prince regent Alexander proclaimed the union of this state with Serbia and Montenegro. Yugoslavia (q.v.) came into being.

Dominated by the Serbs, the new Yugoslav regime showed amalgamating tendencies. These immediately encountered strong opposition from the Croats, who resented encroachments on their national individuality and traditional autonomy. Against the centralizing policy of the Belgrade government they demanded a federal organization of Yugoslavia. After the election of 1920 the Peasant party under Stjepan Radic led Croatian opposition. The assassination of Radic and some of his political collaborators in the Belgrade parliament on June 20, 1928, produced a serious crisis. King Alexander attempted to remedy this by introducing a dictatorial regime in Jan. 1929, but failed to achieve his objective. The Croats organized a solid national front around the Peasant party and obstinately persisted in their demands. Finally, as conflict between Serbs and Croats was preventing the consolidation of Yugoslavia, the Belgrade government had to give in. On Aug. 26, 1939, a settlement, the *sporazum*, was reached whereby Croatia united with Dalmatia and parts of Bosnia-Herzegovina became an autonomous *banovina* within Yugoslavia.

**The Independent State of Croatia.**—Croatian nationalists who aimed at complete independence remained dissatisfied with the *sporazum*. In World War II, after Yugoslavia had been occupied and dismembered by the Axis powers, an Independent State of Croatia was proclaimed in Zagreb on April 10, 1941, and recognized four days later by Hitler and Mussolini. It embraced Croatia-Slavonia, part of Dalmatia and Bosnia-Herzegovina, covered an area of 39,660 sq. mi. and in all had about 6,663,000 inhabitants. Since Vladimir (Vladko) Macek, the leader of the Peasant party, refused the German offer to head the new state, it was entrusted to Ante Pavelic (1889–1959), head of the Fascist terrorist organization Ustasa. A nationalist fanatic, Pavelic re-entered Croatia from Italy, where he had spent 12 years of exile plotting revolution. He ruled his puppet state as a *poglavnik* (leader) and introduced a dictatorial regime characterized by methods of extreme brutality and violence. An attempt was made in 1944 to bring Croatia over to the side of the Allies, but it was mismanaged; its leaders, Ante Vokic and Mladen Lorkovic, were arrested and shot by Pavelic's henchmen.

The Independent State of Croatia survived the capitulation of Germany for a few days only. Pavelic fled to Austria in May 1945 and later to Argentina. The puppet state gave place to the people's republic of Croatia within Communist Yugoslavia.

**The People's Republic.**—The Communists, in the course of

their resistance to the German and Italian occupying forces in World War II, had organized local committees in the territories over which they won control and in 1943 they had subjected their committees to the Anti-Fascist Council of National Liberation of Croatia (Z.A.V.N.O.H.). In May 1945, after the occupation of Zagreb by the partisans, this council became the people's government and Croatia became again an integral part of Yugoslavia. According to the constitution of Jan. 31, 1946, the government's authority "derives from the people and belongs to them"; all natural resources, capital, commerce and means of production were brought under public ownership and managed by the government or by public bodies. Private property remained only on a restricted scale. Peasant holdings were limited to approximately 20 ac.

**Organization.**—The supreme republican authority in Croatia is the *sabor* (parliament), consisting of two chambers: the house of representatives and the council of producers. The *sabor* appoints its executive council, which enjoys autonomous powers in certain specific matters or executes directives from the central Yugoslav government in Belgrade. National committees in the communes, towns and villages have the status of lower governmental agencies in the republic of Croatia. The communes are self-governing communities in an economically interdependent territory; the towns and villages are basic units where public opinion may be expressed in local affairs. Industrial, financial and commercial enterprises are run on behalf of all the workers by workers' committees, but the director, a government nominee, can veto any committee decisions. Collective farms are run in a similar way.

**CROCE, BENEDETTO** (1866–1952), the foremost Italian philosopher of his time, was born on Feb. 25, 1866, at Pescasseroli, Aquila, of an Abruzzese family, the seat of which had been transferred to Naples by his grandfather. There Croce was educated at a Catholic school. In 1883, having lost both his parents in an earthquake, he went to live in Rome with his paternal uncle and guardian, Silvio Spaventa. He entered the university, but did not pursue his studies there. Returning to Naples in 1886, he occupied himself for several years with researches into local history and antiquities. His contributions to philosophy began with two essays (1893 and 1895) on the nature of history and on the method of literary criticism, the leading ideas of which he developed in two later papers in 1900 and 1905. Between 1896 and 1900 he published also a group of essays on points of Marxian economic doctrine. Shortly after, in 1902, he began the systematic exposition of his "Philosophy of the Spirit," divided into four volumes: *Aesthetic*; *Logic*; *Philosophy of Conduct (Economics and Ethics)*; and *Theory and History of Historiography*.

In 1903 he founded the periodical *La Critica*, in which, during the course of the following 41 years, he published, part by part, nearly all his writings and reviewed all the most important historical, philosophical and literary work that was being produced in Europe at the time; and from 1945 until his death he continued this activity in the *Quaderni della "Critica"*, of which 20 numbers appeared at irregular intervals. He became a senator in 1910 and was minister of education in Giovanni Giolitti's last cabinet (1920–21).

In 1925 he drew up the anti-Fascist intellectuals' manifesto, and in 1926 his house was sacked by Fascists; but Mussolini never dared to forbid him to publish. In 1943 Croce refounded the Liberal party, of which he was made president. He was minister without portfolio in the governments of Pietro Badoglio and Ivanoe Bonomi (1944) and a member of the consultative council (1945) and of the constituent assembly (1946–47). In 1947 he founded the Istituto Italiano di Studi Storici (Italian Institute of Historical Studies) in a wing of his own house in Naples.

Within a decade this institute was to produce some notable works in the Crocean tradition. Croce died in Naples on Nov. 20, 1952.

**Philosophy.**—The philosophy of Croce, often erroneously classed as "Hegelian," had its avowed sources in the ideas underlying the literary criticism of Francesco de Sanctis and, more generally and remotely, in those foreshadowed in the *Scienza Nuova* of G. B. Vico—both, like himself, Neapolitans. More significantly, it arises from and perpetually returns to his own personal experience in his lifelong and multifarious activity as a student of literature and history. Here he finds himself in vital touch with concrete reality and deliberately confines his reflections to the content of actual or enacted history with a view to its interpretation. Thus he asserts the identity of concrete philosophy with history and defines the task of abstract philosophy as the discovery and formulation of the immanent methodology of history. From the common domain of both he excludes any supposed "realities" which transcend experience; and he abstains from speculation about such "realities" or about primal origins and ultimate ends. History as enacted and occurring and history as interpreting what is thus "given" he views as the work of one spirit, which there expresses and embodies itself. In every part and moment of history that spirit is wholly and indivisibly present and active. Its presence and operation are not confined to human history, but extend in all directions to the utmost bounds of experience. The spirit which is thus omnipresent throughout the whole content of experience is indivisibly one, but its unity is also a quaternity, and it has in its structure four eternally distinct and distinguishable "grades," the ordered circle of which in its life or progress it perpetually traverses, so endowing or filling itself with experience and ever enriching its being. Its four functions in their conjoint exercise generate the contents of experience, within which we can and must distinguish four corresponding grades, stages, kinds or realms, namely the several subject matters of aesthetic, of logical, of economic and of ethical theory, which together without addition constitute the whole of philosophy.

In its total cognitive function this spirit manifests itself as art, the first or "dawn" form of knowledge. In this grade it expresses itself in individual embodiments; in so expressing itself it at once creates and beholds what it creates and has for its objects (which are also its works) whatsoever in experience presents a characteristic individuality. In its second cognitive grade, as logic or abstract philosophy, it expresses, brings to existence and to view, and so knows whatsoever is universal. Uniting, as it cannot but do, both functions and thus becoming concrete in history, it effects a deductive synthesis between what is individual and what is universal; in doing so, it wins actual understanding of the real and enters upon a course of knowledge which runs from sense perception up to explicit history.

The history which thus comes to be understood is wholly the work of the same spirit in the exercise of its total practical function, which has two corresponding grades, in the lower or earlier of which it enacts what is individual, in the higher or later what is universal, or rather, in its actual or concrete exercise, enacts both in one and so fills the stage of history with its deeds. Still more actually or concretely, it is active at once as making or creating and as knowing or understanding its own history, which is its whole self. The only reality which can truly be called absolute is a history without beginning and without end, self-begotten and self-explaining.

Croce developed and applied this fundamental doctrine in extraordinarily various and often highly novel and even paradoxical ways, which excited widespread interest and evoked abundant criticism and opposition. Against his critics he carried on a sustained and skillful polemic. His influence as a philosopher has been compared by many people with that which Hegel exercised in the 19th century, but the strongly nonacademic and antimetaphysical character of his thought make its effect very different. It is to students of history and to critics of art and of poetry that Croce's antisystematic attitude has proved most congenial; and the expansion of his influence seems likely to be in direct proportion to the usefulness of particular doctrines of his to their work. For a portrait of Croce see ITALIAN LITERATURE.

**CROCE, GIOVANNI** (c. 1557–1609), the leading Venetian composer of his day, was born at Chioggia, near Venice. His teacher, Giuseppe Zarlino, secured him a place in the choir of St. Mark's, Venice. By 1585 he was a priest; in 1595 he became assistant choirmaster at St. Mark's and in 1603 won the competition for the choirmastership. He died in Venice, May 15, 1609. Croce's madrigals and canzonets (publ. in 7 books, 1585–1607), though conservative, were widely admired for his light touch and alert rhythms.

Croce's sacred music (published 1591–1610), including Masses and motets, Magnificats, psalms, etc., shows a development from the manner of Palestrina to the polychoral style associated with Monteverdi, using solo voices, instrumental rhythms and basso continuo.

**BIBLIOGRAPHY.**—Modern reprints include Masses ed. by F. X. Haberl in *Repertorium Musicae Sacrae*, vol. i–ii (1879 and 1886); and four motets in K. Proske (ed.), *Musica Divina*, iv (1863). See also E. Einstein, *The Italian Madrigal* (1949); D. Arnold, "Giovanni Croce and the Concertato Style," in *The Musical Quarterly*, xxxix (Jan. 1953).

**CROCHETING:** see **NEEDLEWORK: Crocheting.**

**CROCIDOLITE:** see **ASBESTOS.**

**CROCKET**, in architecture, a small, independent, sharply projecting medieval ornament, usually occurring in rows, and decorated with foliage. In the late 12th century, when it first appeared, it had the form of a ball-like bud, with a spiral outline, like an uncurling fern frond; but in the later Gothic period it took the form of outcurved, fully developed leaves reaching, in the 15th century, complex, involuted richness. Crockets are used especially on the inclined edges of spires, pinnacles and gables, and are also found on capitals, cornices and, occasionally, around arches.

**CROCKETT, DAVY (DAVID)** (1786–1836), American frontiersman who became a legendary figure of rather fantastic dimensions, was born in a pioneer cabin in eastern Tennessee on Aug. 17, 1786. His father, having little means, hired him out to more prosperous backwoods farmers, and Davy's schooling amounted to 100 days of tutoring with a neighbour.

Successive moves west to middle Tennessee brought Davy close to the area of the Creek War, in which he participated from 1813 to 1815, and which broadened his personal contacts. In 1821 he was elected to the Tennessee legislature, winning popularity through campaign speeches studded with yarns and homespun metaphors. In the legislature an opposing speaker referred to him as the "gentleman from the cane," alluding to the dense canebrakes of western Tennessee where Davy hunted bear and coons during the winter. This image of the rough backwoods legislator caught the popular imagination during Crockett's lifetime and after his death.

Following a second term in the state legislature in 1823, Davy ran for the United States congress. He failed to be elected in 1825, won in 1827 and 1829, lost in 1831, barely won in 1833 and suffered his final defeat in 1835, as a result of concentrated opposition by the party of Andrew Jackson. Thereupon he headed west to Texas, joined the American forces and died with those who were slaughtered at the Alamo by a Mexican army under Santa Anna on March 6, 1836.

During his first congressional term Crockett broke with Andrew Jackson and the new Democratic party, Davy desiring preferential treatment for the squatters occupying land in western Tennessee. The Whigs early courted and publicized Crockett, in the hope of creating a popular "coonskin" politician to offset Jackson. In 1834 he was conducted on a triumphal speech-making tour to Whig strongholds in the east. From the many stories appearing in newspapers and books during his congressional years the legend rapidly

grew of an eccentric, but shrewd, "bar-hunting" and Indian fighting frontiersman.

Actually Crockett engaged in several business ventures, and delivered his speeches in fairly conventional English. A series of Crockett almanacs, appearing from 1835 to 1856, developed the legend along the lines of old world folk epics. In the same period a popular play, *The Lion of the West*, presented the backwoods Crockett in the character of Nimrod Wildfire. A sudden revival in 1955, occasioned by Walt Disney television films about Crockett, spread his name across the United States and to other countries.

The *Autobiography* of David Crockett, which he wrote in 1834 with Thomas Chilton, representative from Kentucky, played up the backwoods scene and said little about politics. It helped introduce a new style of vigorous, realistic writing into American literature.

**BIBLIOGRAPHY.**—The standard modern biography is by James A. Shackford, *David Crockett: the Man and the Legend* (1956). A selection of the almanac legends is given in *Davy Crockett: American Comic Legend* (1939), ed. by Richard M. Dorson, who discussed their epic qualities in "Davy Crockett and the Heroic Age," *Southern Folklore Quarterly*, vol. vi, pp. 95–102 (1942). Different images of Crockett are treated by Walter Blair in "Six Davy Crocketts," *Southwest Review*, vol. xxi, pp. 443–62 (1940).

(R. M. DN.)

**CROCKETT, SAMUEL RUTHERFORD** (1860–1914), Scottish novelist who belonged to the "kailyard school" of writers who made exaggerated use of Scottish dialect, was born at Little Duchrae, near New Galloway, on Sept. 24, 1860. He graduated from Edinburgh university in 1879 and in 1886 became minister of Penicuik, but eventually abandoned the ministry for novel writing. *The Stickit Minister* (1893) and *The Lilac Sunbonnet* (1894) followed the vogue for novels in Scottish dialect set by J. M. Barrie. Later he published a series of retold versions of the tales of Scott. Crockett died on April 21, 1914, at Avignon, France.

See M. M. Harper, *Crockett and Grey Galloway* (1907).

**CROCKFORD, WILLIAM** (1775–1844), proprietor of Crockford's club, was the son of a London fishmonger and for some time he himself carried on that business. After winning a large sum of money, either at cards or by running a gambling establishment, he built, in 1827, a luxurious gambling house at 50 St. James's street, which he organized as a highly exclusive club. Crockford's quickly became the rage: every English social celebrity and distinguished foreign visitor hastened to become a member. Hazard was the favourite game, and very large sums changed hands. Crockford retired in 1840; he had acquired fabulous wealth, but subsequently lost much of his gains in unfortunate speculations. He died in London on May 24, 1844.

**CROCODILE**, a common name for reptiles of the family Crocodylidae, order Crocodilia; the similar term crocodilian is applied to any of the Crocodilia, including also the alligators, caymans and gavials. The true crocodiles, almost exclusively tropical reptiles, are found in greatest variety in South America, where about ten species occur. In size crocodiles range from the Congo dwarf (*Osteolaemus osborni*), averaging 3 ft. long, to the salt-water (*Crocodylus porosus*) of southeastern Pacific distribution, averaging 12–15 ft. *Crocodylus acutus* is the only crocodile that ranges into the U.S., along the Florida Keys. See **CROCODILIA**. See also **ALLIGATOR**.

**CROCODILE BIRD** (*Pluvianus aegyptius*), a ploverlike courser which derives its name from its frequent association with the Nile crocodile (*Crocodylus niloticus*) from the mouth and hide of which it picks and devours parasites. It is also of service to the crocodile by uttering warning cries on the approach of danger. See also **POLOVER**.

A. W. AMBLER FROM NATIONAL AUDUBON SOCIETY

CROCODILE BIRD (PLUVIANUS AEGYPTIUS)

**CROCODILIA**, an order of the vertebrate class Reptilia. The common name crocodilian is applied to any member of the group, though more specific names such as crocodile, alligator and gavial

(qq.v.) are used for certain subgroups. The Crocodilia are members of the Archosauria, or ruling reptiles, the subclass including the dinosaurs. The first recognizable crocodilian appeared in the Triassic (about 175,000,000 years ago), and though the order once flourished, it now includes only about 25 species.

The present-day Crocodilia are placed into three families: Crocodylidae, the true crocodiles; Alligatoridae, the alligators and caymans; and Gavialidae, the true gavia. The last is distinguished by its extremely long, slender snout, by the large number of teeth (more than 22 in each jaw), and by the separation of certain skull bones (nasals and premaxillaries) that are joined in members of the other two families. Both the Alligatoridae and the Crocodylidae have less than 22 teeth in each jaw. In the Alligatoridae the teeth of the lower jaw fit inside those of the upper jaw, whereas in the Crocodylidae the teeth of the two jaws form a single interdigitating row when the jaws are closed. In crocodiles the fourth tooth of the lower jaw fits into an indentation of the upper jaw and is exposed to view when the mouth is shut (see fig. 1). In alligators and caymans this tooth is hidden from view when the mouth is closed, as it fits into a pit of the upper jaw.

Crocodilians are rather uniform in appearance. All of them have a heavy, cylindrical body; a large, triangular head; short legs; and a very strong tail, flattened from side to side. The thick, scaly skin has large, flat plates on the belly and large, keeled ones on the back. Various genera and species differ from this generalized description only in minor ways, one of which is in the outline of the head and snout (see fig. 2).

Although persistent popular reports place the maximum length of present-day crocodiles at 30 ft., authenticated record lengths do not exceed 23 ft. Even the largest species rarely reach such lengths. Most of the big adults of the two largest species, the saltwater crocodile (*Crocodylus porosus*) and the gavia (*Gavialis gangeticus*), fall between 12 and 15 ft. Adults of four other species, the black cayman (*Melanosuchus niger*), Nile crocodile (*Crocodylus niloticus*), American crocodile (*Crocodylus acutus*) and Orinoco crocodile (*Crocodylus intermedius*), commonly exceed lengths of ten feet. Two species of smooth-fronted caymans (*Paleosuchus*) and two species of African dwarf crocodiles (*Osteolaemus*) are less than six feet as adults.

With the exception of the American alligator (*Alligator mississippiensis*) and the Chinese alligator (*Alligator sinensis*), all contemporary crocodilians are confined to the tropics and subtropics. All are amphibious in habit, living in and along lakes, marshes and rivers. Though a number of extinct forms were marine, today only one species, the salt-water crocodile of the East Indies and adjacent areas, habitually swims out to sea.

All crocodilians are powerful swimmers, the heavily muscled, flattened tail driving them through the water while the limbs are held pressed against the sides.

Valves prevent water from entering certain body openings while the animal is submerged. The nostrils, which are at the tip of the snout, are surrounded by muscles that by their contraction close these openings. At the rear of the head the ear openings are protected by muscular flaps that can be pressed tightly against the surrounding surfaces. Because the skin is directly attached to the skull without muscular padding and because there are no fleshy lips, water cannot be prevented from entering the mouth, but it is

kept out of the throat by a large muscular flap that closes off the rear of the oral cavity.

Crocodilians frequently float at the surface of the water, with only the tip of the snout and the eyes (atop the head) projecting. In this position, too, the valve at the throat is closed. A pair of bony tubes runs through the skull from the nostrils to a point behind the level of the throat valve. With this apparatus a crocodilian can breathe as long as the tip of the snout is above the surface of the water.

In the floating position a crocodile waits for potential prey, often a small mammal, to come to the water's edge to drink. When it sees the prey, the crocodile submerges, almost without a ripple, and cautiously swims toward the animal till it is only 20 feet or so away; then the crocodile abandons caution and with one or two powerful beats of its tail is upon the startled quarry. The prey, seized between the crocodile's gaping jaws, is pulled into the water and drowned. Small prey is crushed to death in the crocodile's viselike grip.

Most crocodilians feed on fishes, turtles, birds and mammals, including animals that are too large to swallow whole. Once large prey—as big as a deer or cow in the case of the largest crocodiles—is drowned it is dismembered. This is often accomplished by the crocodile's spinning rapidly on its longitudinal axis while gripping a limb of the prey until the limb is twisted off the body. Baby crocodilians usually feed on insects and other small invertebrates. The diet changes as the crocodilians grow, gradually including more and more vertebrates and larger prey. The gavia and the slender-snouted species of crocodiles, such as the so-called false gavia (*Tomistoma schlegelii*), feed almost exclusively on fishes, which are caught by rapid sidewise motions of the snout.

A few species, notably the salt-water crocodile and the Nile crocodile, are known to attack and eat men on occasion. Not all adults of these species will attack a man, but large individuals must be considered dangerous animals.

Food is swallowed in large chunks, as crocodilians are unable to chew. Mechanical reduction of the food into smaller bits takes place in the heavily muscled stomach and is promoted by the grinding action of gastroliths, or stomach stones, which the crocodilian picks up from the stream bed. Powerful contractions of the stomach move the gastroliths among the chunks of food.

All crocodilians reproduce by means of eggs that are laid on land. The female American alligator makes a moundlike nest of mud and decaying vegetation. When completed, the nest is usually about three feet high and six feet across. The whitish, hard-shelled eggs, about three inches long and 20 to 70 in number, are laid in a hollow in the centre of the nest and then covered with debris. The Nile crocodile deposits its 30 to 50 eggs in sand. The nest, excavated by the female in a river bank, is usually 1½–2 ft. deep. Heat to promote incubation is provided by the sun in the case of sand nests or by decaying vegetation in the case of the alligator's mound nest. The female loosely guards the nest against egg predators. In the southern United States, raccoons and other animals may dig up and eat the eggs.

After the young hatch, which takes approximately nine weeks for the American alligator, the female is attracted to the nest by the peeping calls of the hatchlings; she helps them to leave the nest by scratching away the debris cover. At hatching the young are roughly three times the length of the egg. They are immediately able to fend for themselves, and the female pays no further attention to them. Growth in the early years is rapid and in the larger species approximates one foot each year. After the first five or six years the animal grows much more slowly.

Crocodilians are long-lived. Individuals of both species of alligators have been known to live more than 50 years in captivity, and many American alligators have been kept more than 30 years. Although the maximum recorded life of a true crocodile in captivity is 22 years (for an Orinoco crocodile), presumably crocodiles are potentially capable of living even longer. Probably few crocodilians live more than 30 years in the wild, where they must contend with enemies at all times.

The most menacing of the crocodile's enemies is man. Many species of crocodilians are facing extinction at the hands of hide

FIG. 1.—AMERICAN CROCODILE (*CROCODYLUS ACUTUS*), SIDE VIEW SHOWING PROTRUDING 4TH TOOTH. ONE OF THE FEATURES THAT DISTINGUISHES THE CROCODILES FROM THE ALLIGATORS

FIG. 2.—DORSAL VIEW OF CROCODILIAN HEADS: (A) GAVIAL; (B) CROCODILES; (C) ALLIGATORS AND CAYMANS

Spectacled caiman (*Caiman sclerops*), whose length rarely exceeds six feet, is widely distributed throughout the Amazon and Orinoco basins, the Guiana region and northeastern Brazil

True gaviel (*Gavialis gangeticus*), common in the Indus, Ganges, Mahanadi and Brahmaputra river systems of Indian region of southern Asia

Siamese crocodile (*Crocodylus siamensis*), found in southern Vietnam, Thailand and the northern part of the Malay peninsula

American alligator (*Alligator mississippiensis*), one of the two species of crocodilians found in the U.S., inhabits the swamps, rivers and lakes of southeastern U.S., from the Carolinas to Texas

**CROCOITE**, a mineral consisting of lead chromate, is identical in composition ( $PbCrO_4$ ) with the artificial product chrome-yellow used in paint. It is found as well-developed crystals of a bright hyacinth-red colour, which are translucent and have an adamantine to vitreous lustre. On exposure to light much of the translucency and brilliancy is lost. Crystals were first found in the Urals in 1763 in quartz veins traversing granite or gneiss. Gold is often found associated with this mineral. Crystals far surpassing in beauty any previously known have been found in the Adelaide mine at Dundas, Tasmania. They are long, slender prisms, three or four inches in length, with a brilliant lustre and colour. In the United States crocoite has been found in California and Arizona. Crocoite crystallizes in the monoclinic system. The streak is orange-yellow; hardness 2.5 to 3; specific gravity 6.0. (L. J. S.)

**CROCUS.** A genus of over 80 species of popular ornamental plants of the iris family (Iridaceae; *q.v.*), from Eurasia, especially in the drier regions, containing about a dozen species widely cultivated for ornament. The thickened underground stem, the so-called "bulb," is actually a corm (see STEM).

Crocuses as garden plants are divided into at least two groups:

- (1) the familiar spring-flowering species; and (2) the autumn-flowering sorts that are not so well known. Of the first group, which should be planted in the autumn for next season's bloom, the most popular are *C. vernus*, the common crocus of most gardens, initially violet or blue, but now in many other colours; *C. moesiacus*, the Dutch crocus, with yellow flowers; *C. susianus*, the cloth-of-gold; and *C. imperati* from Italy, which is one of the earliest to bloom and has lilac

J. HORACE MCPARLAND CO.  
CROCUS VERSICOLOR

or white, purple-striped flowers.

Of the autumn-blooming species (not to be confused with the autumn crocus; see COLCHICUM) the finest is the saffron crocus (*C. sativus*) with white or lilac flowers, the orange stigmas of which are the source of saffron (*q.v.*). Corms of fall-blooming crocuses should be planted in midsummer for bloom eight weeks later. (N. Tr.; X.)

**CROESUS**, last king of Lydia (c. 560-c. 546 or 540 B.C.), of the Mermnad dynasty, succeeded his father Alyattes after a struggle with his half brother. He is said to have acted as viceroy and commander in chief before his father's death. He completed the conquest of Ionia by capturing Ephesus and other mainland cities, but lack of sea power forced him to give up his project of subduing the islanders, whom he enlisted as allies. He also allied himself with Sparta. His wealth was proverbial. He was a client of the oracle at Delphi, where a number of rich gifts of his were seen by Herodotus. Various legends were told about him by the Greeks, one of the most famous being that of Solon's visit to him with the lesson it conveyed of the divine nemesis that waits upon excessive prosperity (Herodotus i. 29, *et seq.*). (The story is discredited, however; see SOLON.) After the overthrow of the Median empire Croesus found himself confronted by the rising power of Cyrus the Great, and along with Nabonidus of Babylon took measures to resist it. A coalition was formed between the Lydian and Babylonian kings; Egypt and Sparta promised troops, and Croesus took

the initiative by invading Cappadocia. After a supposedly indecisive battle at Pteria he returned to Sardis to gather the forces of the confederacy. Cyrus followed him, took him completely by surprise, and stormed Sardis (c. 546 or 540). From Bacchylides it may be gathered that Croesus hoped to escape his conqueror by burning himself on a funeral pyre, but that he fell into the hands of Cyrus. A different version of the story is given (from Lydian sources) by Herodotus (followed by Xenophon), who makes Cyrus condemn his prisoner to be burned alive; Apollo, however, came to the rescue of his worshiper with a rainstorm, and the name of Solon uttered by Croesus resulted in his deliverance. According to Ctesias, who uses Persian sources, and says nothing of the attempt to burn Croesus, he subsequently became attached to the court of Cyrus and received the governorship of Baren in Media. Herodotus makes him accompany Cyrus' successor Cambyses to Egypt. Fragments of columns from the temple of Artemis at Ephesus now in the British Museum have upon them a dedication by Croesus in Greek. See also LYDIA; and for his coinage, NUMISMATICS.

**CROFT, SIR HERBERT, BART.** (1751-1816), English author, who planned a revised edition of Johnson's *Dictionary*, contributed a life of Edward Young to his *Lives of the Poets* and achieved notoriety by *Love and Madness*, a collection of love letters which included material on Thomas Chatterton. His scholarly and linguistic gifts were shown in a critical French dictionary and in a number of other books in French. Croft was born on Nov. 1, 1751, at Dunster Park, Berkshire. He became vicar of Prittlewell, Essex, in 1786, but spent much time in France, and died in Paris, April 26, 1816. His plan for revision of Johnson's *Dictionary* was frustrated by lack of money, like many of his ventures.

Croft's *Love and Madness, a Story too true, in a series of letters between Parties whose names could perhaps be mentioned were they less known or less lamented* (1780), was a collection of letters supposedly exchanged between Martha Ray, the mistress of Lord Sandwich, and a clergyman who was in love with her and eventually shot her. It is less interesting for its revelations of this forgotten story than for its inclusion of Chatterton's letters and of a memoir based on then unpublished material.

**CROFT, WILLIAM** (1678-1727), English organist and composer chiefly of church music, was born at Nether Ettington, Warwickshire, and received a musical education at the Chapel Royal under John Blow. He was organist of St. Anne's, Soho, from 1700 till 1712, of the Chapel Royal from 1707, on the death of Jeremiah Clarke, and of Westminster abbey from 1708. In 1700 he collaborated with Clarke, Blow, Francis Piggott and John Barrett in a *Choice Collection of Ayres for the Harpsichord or Spinnet*. In 1724 appeared his *Musica sacra, or Select Anthems in Score* containing a setting of the burial service of the Church of England that remains in use in the 20th century. Croft's occasional anthems, such as "I will give thanks," for the victory at Blenheim (1704), contain some of his best writing. He also wrote incidental music and works for violin, voice and harpsichord. He died at Bath on Aug. 14, 1727. (C. A. L.)

**CROFTER**, a term used, particularly in the Highlands and islands of Scotland, to designate a tenant who rents and cultivates a small holding of land or "croft." This Old English word, meaning originally an enclosed field, seems to correspond to the Dutch *kroft*, a field on high ground or downs. By the Crofters' Holdings (Scotland) act, 1886, a crofter was defined as the tenant of a holding who resides on his holding, the annual rent of which does not exceed £30 in money and which is situated in a crofting parish. The law relating to "crofters," *i.e.*, those holding crofts in the "crofting counties" of Argyll, Caithness, Inverness, Orkney, Ross and Cromarty, Sutherland and Zetland, was consolidated in the Crofters act of 1955, which also established a Crofters' commission for developing and regulating the crofting way of life. (A. D. G.)

**CROGHAN, GEORGE** (1720?-1782), American colonist, Indian agent and trader, who migrated from Ireland to Pennsylvania in 1741. He settled on the Pennsylvania frontier near Carlisle. His early success in the Indian trade—the exchange of textiles, hardware and other items for furs and skins—was facilitated by his mastery of Indian customs and languages. He was also aided by his association with William Trent, an educated young trader,

who had established business connections with Philadelphia merchants who supplied goods for the Indian trade. The rapid extension of Croghan's trading enterprises into the villages of the Ohio Iroquois, the Delawares, the Shawnees and the Miamis led to his appointment as an Indian agent for the province of Pennsylvania in the 1740s.

After the outbreak of the French and Indian War in 1754, Croghan's far-flung trading business collapsed. In 1756 he accepted an appointment as deputy for Sir William Johnson, British superintendent for the northern Indians. As Johnson's chief deputy, a post he held for 15 years, Croghan in the 1750s and 1760s conducted extensive negotiations with the northern tribes, who complained of abuses in the fur trade and encroachments on their lands. He appears to have had a part in negotiating most of the important Indian treaties of the period. When he was sent to the Illinois country to open it for British occupation, he met the great Ottawa chief Pontiac for final peace negotiations and at the same time planned a land speculation project for the Illinois area. Croghan later represented the British government at the important treaty at Ft. Stanwix, N.Y., in 1768, and retired from the Indian service four years later. During the American Revolution he was loyal to the patriot cause, although his land speculation designs caused him to be under suspicion of disloyalty. He cleared himself of charges in 1778 but was unable to establish his title to thousands of acres in western Pennsylvania. He also lost huge landholdings in New York through forced sales and mortgages.

Throughout his career Croghan was involved in many land speculation schemes and trading enterprises that left his name on many 18th-century maps. He died impoverished on Aug. 31, 1782. Croghan's chief contribution to American history is his record as an Indian agent in the period before the American Revolution. He demonstrated that he was, in many respects, the ablest peacemaker in this period of Indian diplomacy in the North American wilderness.

**CROISSY, CHARLES COLBERT, MARQUIS DE** (1625-1696), French statesman who, as Louis XIV's foreign minister from 1679, was chiefly concerned with the policy of annexation through "chambers of reunion," was the younger brother of the great Jean Baptiste Colbert (q.v.). He began his career in the office of the minister of war, Michel le Tellier. In 1656 he bought a counselorship at the *parlement* of Metz, and was appointed intendant of Alsace. He was made president of the sovereign council of Alsace in 1657 and served as *président à mortier* in the *parlement* of Metz (1662-63). Having also held other intendencies (1661-67), he was in 1668 made intendant of Paris, but he delegated this charge until 1675. During this time he represented France at the conference of Aix-la-Chapelle (1668) and went on a mission to London (1670-74) to secure Charles II's co-operation against Holland. In March 1675 he was sent as an envoy to Nijmegen.

The intendency of Alsace, his duties at Metz and a diplomatic mission to Vienna (1660) had made Colbert de Croissy acquainted with the complex affairs of the Holy Roman empire. In Alsace he had drawn up a detailed statement of the king's rights and had tried to strengthen the royal authority there so as to put the country's affairs in order, thus starting the process which transformed the mosaic of towns and fiefs into a province ready for incorporation into France. Likewise, during the Nijmegen negotiations (1675-78), he obtained the confirmation of the French king's rights in Alsace, despite the resistance of the emperor's envoys. He was then made secretary of state for foreign affairs (1679).

Colbert de Croissy's purpose was to claim all territories that had been feudally dependent on provinces already ceded to France under the recent treaties. This was not a new theory, but to apply it effectively was a difficult undertaking. To do so, "chambers of reunion" were set up at Douai, Besançon, Breisach and Metz. These studied the evidence of feudal dependence and thereupon declared the several territories to be reunited with France. The consequent reunions were considered by the empire as annexations

in time of peace. Historians still debate whether the original responsibility for this policy belongs to the marquis de Louvois or to Colbert de Croissy. Louvois seems to have had much to do with its application in Alsace, but even there the program had already been prepared by Colbert de Croissy. From all angles, Colbert de Croissy identified himself with the policy as a whole.

To counteract the resentment provoked by the annexations, Colbert de Croissy sought alliances with German princes within the empire (e.g., Brandenburg in 1681) and also concluded one with Denmark (1683), but these lapsed. The League of Augsburg was formed against France, and by 1688 war had become inevitable (see *GRAND ALLIANCE, WAR OF THE*). After Colbert de Croissy's death, at Versailles on July 28, 1696, Louis XIV recalled the more moderate Arnauld de Pomponne to the ministry of foreign affairs.

Colbert de Croissy's papers are in the archives of the French ministry of foreign affairs. Some are printed in the *Recueil des instructions données aux ambassadeurs et ministres de France*, 17 vol. (1884-1901). Other documents are edited by F. A. M. Mignet in *Négociations relatives à la succession d'Espagne*, vol. iv. (1842).

**CROKER, JOHN WILSON** (1780-1857), British politician and writer famous for his critical severity as a reviewer and for his rigid Tory principles, was born at Galway, Ire., on Dec. 20, 1780, the elder son, by his second marriage, of John Croker, surveyor general of customs and excise for the port of Dublin. He graduated at Trinity college, Dublin, in 1800 and after a period at Lincoln's Inn he was called to the Irish bar in 1802.

In 1804 his anonymous verse satire *Familiar Epistles to Frederick E. Jones, Esquire, on the Present State of the Irish Stage* achieved great success and notoriety, as did also a number of anonymous prose pamphlets on Irish society and affairs, including the satirical *Intercepted Letter From Canton* (1804) and the more serious *Sketch of the State of Ireland, Past and Present* (1808) which advocated Catholic emancipation.

In 1807 Croker entered parliament as member for Downpatrick and made his first speech, unprepared, on the day he took his seat. From the first he had the backing of the duke of Wellington, then Sir Arthur Wellesley and chief secretary for Ireland, and the friendship between them continued unbroken until the duke's death. Croker was given a leading part in the Tory defense of the duke of York against the charges of Colonel Wardle and in 1810 his abilities were recognized by Spencer Perceval in his appointment to the office of secretary to the admiralty, which he held until 1830, when the Whigs returned to power. Croker's official career began with a spectacular exposure of a colleague's misappropriation of public funds. He built up the importance of the office, resisted the attempts of the duke of Clarence (afterward William IV) to make himself, as lord high admiral, independent of the admiralty council and encouraged nautical science and exploration.

Croker played a leading part in the opposition to the Reform bill, replying frequently to Macaulay's advocacy, and he refused to sit in the reformed parliament. After 1832, however, he remained in close contact with the Tory leaders, especially Sir Robert Peel, until the latter's conversion to the repeal of the corn laws split the party. From 1831 to 1854 Croker was the chief political writer for the *Quarterly Review*, with which he had been connected from its foundation and to which, between 1809 and 1854 he contributed about 270 articles on a great variety of subjects. In politics a staunch Tory of the older school, Croker wrote with intense party feeling and his reputation suffered from the attacks of his political opponents, especially Macaulay. The quarrel produced Macaulay's unfair review of Croker's edition of Boswell's *Life of Johnson* (1831) and Croker's later damaging criticism of the first two volumes of Macaulay's *History of England* (1849).

His literary tastes were largely those of the 18th century, as may be seen from his severe criticisms of Keats's *Endymion* and Tennyson's *Poems* of 1832. For some years before his death he had been accumulating material for an annotated edition of Pope's works; this passed to Whitwell Elwin, who began the edition later completed by W. J. Courthope. Croker was a frequent reviewer of contemporary history and memoirs and an authority on the French Revolution; at his death his valuable collection of documents on this subject was left to the British museum, London. He edited *Letters to and from Henrietta, Countess of Suffolk* (1824) from the *Suffolk Papers* (then in his possession and later bequeathed to the British museum), also John, Lord Hervey's *Memoirs of the Reign of George II* (1848), the *Letters of Mary Lepel, Lady Hervey* (1821) and *Walpole's Letters to Lord Harford* (1825). Croker did much to further public encouragement of the arts and sciences, was concerned in the purchase of the Elgin Marbles (1816) and was principal founder of the Athenaeum club. He died at Hampton, Middlesex, on Aug. 10, 1857.

See L. J. Jennings (ed.), *The Croker Papers*, 3 vol. (1884); Myron F. Brightfield, *John Wilson Croker* (1940). (R. G. Cx.)

**CROKER, THOMAS CROFTON** (1798–1854), Irish antiquary whose collections of songs and legends formed a storehouse for writers of the Irish literary revival, was born at Cork, Jan. 15, 1798. During rambles in southern Ireland, 1812–16, he collected legends, folk songs and keens, some of which he sent to Thomas Moore, who acknowledged a debt to him in his *Irish Melodies*.

This collection formed the basis of Croker's *Fairy Legends and Traditions of the South of Ireland* (1825–28), which was praised and translated into German by the brothers Grimm, and by Sir Walter Scott, who described Croker as "little as a dwarf, keen-eyed as a hawk, and of easy prepossessing manners." After 1818 Croker lived in England, working as clerk in the admiralty until 1850. His later works included *Popular Songs of Ireland* (1839), and publications for the Percy society of which he was co-founder (1840). He helped to found the Camden society (1839) and the British Archaeological association (1843). He died in London, Aug. 8, 1854.

**CROLL, JAMES** (1821–1890), Scottish scientist best known for his theory that the glacial ages were caused by a change in the eccentricity of the earth's orbit combined with the precession of the equinox, was born near Cargill, Perthshire, Jan. 2, 1821. He was self-educated, but in 1859 was made keeper of the Andersonian museum in Glasgow, and from 1867 to 1880 was in charge of the Edinburgh office of the geological survey of Scotland. He wrote some books, much discussed in their day, including *Climate and Time, in Their Geological Relations* (1875) and *Climate and Cosmology* (1885). His *Autobiographical Sketch of James Croll, With Memoir of His Life and Work* was edited by J. C. Irons (1896). Croll died near Perth on Dec. 15, 1890.

**CROLY, GEORGE** (1780–1860), British author and Anglican clergyman whose vigour and eloquence as a preacher were apparent also in his poetry and prose, although marred by a turgid and extravagant style, was born in Dublin on Aug. 17, 1780. Educated at Trinity college, Dublin, he received a curacy in the north of Ireland. About 1810 he moved to London, where he wrote for literary journals and published several poetical works, including *Paris in 1815* (1817) in the manner of Lord Byron's *Childe Harold*. *Solathiel* (3 vol., 1828) was his chief novel, but he wrote many other prose works on history, religion and biography, all in an elaborate and unreal style lacking in humour and imagination.

Through his patron, Lord Brougham, in 1835 Croly received the living of St. Stephen's, Walbrook, London, where he died on Nov. 24, 1860.

**CROLY, HERBERT DAVID** (1869–1930), U.S. author, editor and political philosopher, was born in New York city, Jan. 23, 1869. Both of his parents were widely known journalists. Educated in public and private schools of New York city and at Harvard university, he spent his early adult years editing or contributing to architectural journals. His first book on social and political problems, *The Promise of American Life* (1909), was also his most important; it influenced both the "New Nationalism" of the Republican president Theodore Roosevelt and the "New Free-

dom" of the Democratic president Woodrow Wilson. In 1914 Croly founded the weekly *New Republic*, "A Journal of Opinion," gathering about him a distinguished staff. The paper, which began publication just after the opening of World War I, gained rapidly in circulation, partly because it was supposed (incorrectly) to be a mouthpiece for President Wilson. When the terms of the treaty of Versailles were published in 1919, Croly denounced them, an act that cost his paper half its circulation.

Croly was the first important writer to attack American complacency and to argue that democratic institutions must constantly be revised to fit changing situations. While a true democrat, he believed in dedicated leaders of superior quality; it was said of him that "he sought Jeffersonian ends by Hamiltonian means." In his last years, disillusioned by Pres. Warren G. Harding's "return to normalcy," he gave his attention chiefly to philosophic and religious questions.

Croly's other works include *Progressive Democracy* (1914), biographies of Marcus A. Hanna (1912) and Willard Straight (1924) and several books on architecture. He died in New York city on May 17, 1930. (B. Bl.)

**CRO-MAGNON MAN**, the name originally given to a small number of human skeletons of prehistoric age found in a rock shelter at Cro-Magnon near Les Eyzies in the Dordogne department of France. It has since been used with reference to a prehistoric race of such men which inhabited western Europe, and is generally associated with the Aurignacian culture. (See FRANCE: *Archaeology*.) The discovery at Cro-Magnon was made in 1868, when workmen engaged in constructing a railway from Périgeux to Agen unearthed remains of more than five human skeletons, together with animal bones, sea shells in the form of necklaces and stone tools. Louis Lartet, a geologist, carefully excavated the site and published his findings that year. The stone tools were similar to those which had been discovered in 1860 at Aurignac by Lartet's father, Édouard, and which were given the name Aurignacian. The skeletons themselves were fragmentary, but three crania were fairly well preserved and, in particular, one of a senile man, popularly known as "le Vieillard." This important discovery was the first to be made of human fossils in a recognizable archaeological context acknowledged to be of pre-Neolithic age—in fact, the first man of the Paleolithic (q.v.) to be scientifically excavated.

**Distribution.**—The discovery was important not only because of its early date but because the skeletons proved to be typical of a race widespread throughout Europe at this time, most common in France, but stretching north to Belgium and from Wales to eastern Europe. These early discoveries of Old Stone Age man were made toward the end of the 19th century, and grouped together by French archaeologists as the race of Cro-Magnon. This wide area has now proved to contain a rather varied number of slightly differing peoples throughout the length of the later Old Stone Age, and the term Cro-Magnon is more generally used with reference to people occupying southwestern France in the Aurignacian period. Skeletal remains of this period have been discovered at Combe Capelle, Menton, Les Cottés, Isturitz and elsewhere.

**Origin.**—Placed in their historical context, the physical or anatomical characteristics of these people are very striking because they are entirely different from the distinctively specialized Neanderthal man (q.v.), whom they follow and replace chronologically. In a short space of time—geologically speaking—Neanderthal man was entirely replaced in this same geographical area by men of the Cro-Magnon type, whose physical characteristics, origin and culture were entirely different from those of the earlier inhabitants. This change occurred just after the coldest stage of the first glaciation of the last ice age when, in many archaeological sites, the Mousterian culture of Neanderthal man was replaced by the Aurignacian culture of the Cro-Magnon people. Since there is no true cultural or anatomical continuity in these western European sites between these two groups, it has generally been assumed that either the extremely cold climate or the more intelligent and skilled Cro-Magnon people caused the annihilation of Neanderthal man. The available archaeological and anatomical evidence suggests that the Cro-Magnon type of man evolved farther east, in Asia, and moved westward into Europe to replace its earlier inhabitants. Farther

east, some degree of anatomical continuity can be traced between the two groups.

**Physical Characteristics.**—Cro-Magnon man contrasts with Neanderthal man (*Homo neanderthalensis*) by being entirely modern in physical characteristics. In classification he falls into the "caucasoid" subspecies of modern man, *Homo sapiens sapiens*. These early Europeans had only a few characteristics which would serve to distinguish them from some modern western and north Europeans. In particular, they had a large brain (1,550–1,750 c.c.) and were tall and muscular in comparison to modern man (average brain size 1,350 c.c.). The skull was large, pentagonal and dolichocephalic (long-headed). The face was broad and short, with well-separated and low, broad, rectangular orbits; the mouth rather narrow and prognathous; the *foramen magnum* (the opening in the skull for the spinal column) relatively long. The original Cro-Magnon fossils were described by P. Broca and F. Pruner-Bey in 1868. They are to be seen in the Musée de l'Homme, Paris.

**Ecology.**—Cro-Magnon man was a food gatherer and subsisted primarily by hunting. After the first glaciation of the last ice age the glaciers moved back northward, the arctic conditions being replaced in turn by a tundra and steppe fauna and flora. The open plains were well stocked with bison, musk oxen and horse, while the cooler regions carried the great mammoth, the woolly rhinoceros, reindeer and many other animals. Working with his fellows in groups, man had mastered the art of hunting these large and dangerous animals, and possibly the commonest method of capture was to stampede a herd of animals over a cliff, or into a narrow ravine. Besides being a source of meat, the animal skins supplied man with clothing and shelter, the fat was used for oil lamps, and the bones and ivory made possible an enormous development in toolmaking. The rivers were certainly full of fish, and Cro-Magnon man was developing techniques for catching them.

During the winter and in the later colder periods, the overhanging rock shelters and cave mouths, which are so common in limestone areas, provided shelter. Perhaps the need for this shelter, and the increasingly complex material culture, served to some extent to anchor this otherwise nomadic people. In these shelters the dead were placed in shallow graves, and in this characteristic the Cro-Magnon people resembled Neanderthal man, who also must have believed in an existence after death, which is indicated by the burial custom. Red ochre was probably used extensively as a body paint, as in modern tribes, as well as to colour the bodies of the dead.

**Material Culture and Date.**—Today it is usual to associate the Cro-Magnon race with the Aurignacian industry in its original sense, for it has more recently been divided into the Châtelperronian, Aurignacian and Gravettian industries. It is convenient to treat as one race these men who occupied Europe subsequent to the first glaciation of the last ice age, becoming more numerous toward the end of this period, and who were responsible for this culture sequence. In the early 1960s there was still insufficient evidence to distinguish the "races" of Grimaldi, Predmost and Chancelade, as had been done by some authors. Cro-Magnon man was not only responsible for a very fine stone and bone industry but for the first art. Small engravings, reliefs and sculptures of animals have been found, as well as statuettes in mammoth ivory and fine-grained rock depicting grotesque female figures, often apparently pregnant, and very likely designed to affect magically the fertility of the tribe. Bone implements are sometimes decorated with geometric patterns. Most striking, however, are the superbly painted caves, some of which, including the famous cave at Lascaux, are probably of late Aurignacian date. The art, however, had a definite function, and the animals depicted in the caves were undoubtedly intended to influence magically the success of the hunting expeditions upon which the survival of the community depended. But these artistic achievements show a sensitivity of observation, a technical ability and a creative consciousness which prove Cro-Magnon man to have been a highly evolved human being, both physically and mentally. Radiocarbon age determinations from certain sites in France suggest that the earliest known Cro-Magnon skeletal remains date from about 30,000 years B.C., though cultural evidence suggests that the Cro-Magnon race entered western Europe

5,000–10,000 years earlier.

**Theories on Fate.**—The Cro-Magnon people were from time to time invaded by others coming from the east. New populations, bearing new culture traits, moved westward and occupied successively the former strongholds of Cro-Magnon man. But the Cro-Magnon folk survived, and the modern dolichocephalic inhabitants of western Europe are not far removed anatomically from their prehistoric forebears. There seems no reason to doubt that these modern groups are descended to some extent from people similar to those whose skeletons have been discovered in these Upper Paleolithic sites. A close resemblance to Cro-Magnon man has been noticed by anthropologists in certain living groups in the Dordogne, and in Scandinavia, parts of Spain and the Canary Islands. Thus, human skeletons bearing the Cro-Magnon characteristics occur throughout the Solutrean, Magdalenian and later prehistoric cultures until the present day. They have been found in many sites besides those of Aurignacian date cited above. See also *ARCHAEOLOGY: Prehistory; MAN, EVOLUTION OF*.

**CROMARTY, GEORGE MACKENZIE**, 1ST EARL OF (1630–1714), Scottish statesman who held political office in Scotland both before and after the revolution of 1688–89, was born at Innerteil, Fife, in 1630 and educated at Aberdeen university. He joined the Scottish rising on behalf of Charles II in 1654 and was in exile until the Restoration, when he became a lord of session with the title of Lord Tarbat (1661). The king's commissioner in Scotland was the earl of Middleton, who had led the rising in 1654, and Mackenzie, as a member of parliament, worked with him against the earl of Lauderdale. The latter's predominance in Scottish affairs kept Mackenzie out of office from 1664 to 1678, but he subsequently became lord justice general (1678), lord clerk register and again a lord of session (1681). From 1682 he was a leading member of the government of Charles II and James VII (James II of England) in Scotland. In 1689 he was arrested, but soon made his peace with William III for whom he acted in framing the church settlement and mediating with the episcopalian party and the Highland clans. Again in office as lord clerk register (1692–96), a secretary of state (1702–04) and lord justice general (1705–10), he was, in the last phase of his inconstant career, an advocate of the union of 1707. He received his earldom in 1703 and died in Ross-shire on Aug. 17, 1714. (GN. D.)

**CROMARTY**, a small burgh and seaport of Ross and Cromarty, Scot., 3½ mi. E.N.E. of Inverness by road. Pop. (1961) 605. It is situated in the Black Isle near the mouth of the Cromarty firth under the shelter of the South Sutor—one of the headlands which guard the entrance to the fine landlocked harbour. Before the union of the shires of Ross and Cromarty it was the county town of Cromartysire and gave the title to the earldom of Cromarty. A flourishing fishing industry was once carried on, but this practically disappeared and the town became a summer resort. The parish is rich in historical legends and folklore. Behind the town stands a monument to Hugh Miller (1802–56), the geologist and writer, and the thatched cottage in which he was born is now maintained by the National Trust of Scotland. Sir Thomas Urquhart, translator of François Rabelais, was born where Cromarty house now stands; the Saltire society has placed a tablet to his memory in the old parish church which is an early post-Reformation building. The former shire of Cromarty was incorporated with Ross-shire in 1889. Its nucleus consisted of the lands of Cromarty in the north of the peninsula of the Black Isle. To this were added from time to time the various estates scattered throughout Ross-shire—including the districts around Ullapool and Little Loch Broom and a tract to the north of Loch Fannich—which was acquired by the ancestors of Sir George MacKenzie (1630–1714), afterward Viscount Tarbat (1685) and 1st earl of Cromarty (1703). Desirous of combining these properties into one shire, Viscount Tarbat procured their annexation to his sheriffdom of Cromarty in 1685 and 1698. (See ROSS AND CROMARTY.) Invergordon, 5 mi. W.N.W. on the opposite coast, is in

regular communication with Cromarty by motorboat. At Invergordon is a naval base which gained notoriety as a centre of a naval mutiny in 1931. Nigg, across Nigg bay from Invergordon, has a church with a strange sculptured stone possibly dating to the 7th century.

**CROME, JOHN** (1768–1821), English landscape painter, founder and chief representative of the "Norwich school"—often called Old Crome, to distinguish him from his son—was born at Norwich on Dec. 22, 1768, the son of a weaver. During his apprenticeship to a house painter he sometimes painted signboards, and devoted what leisure time he had to sketching from nature. Through the influence of a rich art-loving friend he was enabled to become a drawing master, and in this he was engaged throughout his life. About 1790 he was introduced to Sir William Beechey, from whom he gathered additional knowledge and help in his art. In 1805 the Norwich Society of Artists took definite shape. Crome was its president and the largest contributor to its annual exhibitions.

Crome first exhibited at the Royal academy in 1806. With few exceptions his subjects were taken from the familiar scenery of his native county, which he depicted with techniques largely derived from his study of Dutch painters, particularly Hobbema. Fidelity to nature was his dominant aim. His most important works are: "Mousehold Heath, near Norwich"; "Clump of Trees, Hautbois Common"; "Oak at Poringland"; the "Willow"; "Coast Scene near Yarmouth"; "Bruges, on the Ostend River"; "Slate Quarries"; the "Italian Boulevards"; and the "Fishmarket at Boulogne." He executed a good many etchings, and the great charm of these is in the beautiful and faithful representation of trees. He died at Norwich on April 22, 1821. His son, John Bernay Crome (1794–1842), was his assistant in teaching, and the younger Crome's best pictures were in the same style. A collection of "Old" Crome's etchings, entitled *Norfolk Picturesque Scenery*, was published in 1834, and was reissued with a memoir by Dawson Turner in 1838, but in this issue the prints were retouched by other persons. See also PAINTING: *Baroque Through Impressionist Painting: Great Britain*.

**CROMER, EVELYN BARING, 1st EARL** (1841–1917), British administrator and diplomat whose 24-year rule in Egypt profoundly influenced its development as a modern state, was born at Cromer hall, Norfolk, on Feb. 26, 1841, of a family distinguished in political life and merchant banking. He was commissioned in the royal artillery in 1858 and spent the first years of his service in the Ionian Islands, Malta and Jamaica. Returning to England he passed through the staff college and was posted to the war office. He went to India in 1872 as private secretary to his cousin, Lord Northbrook, the viceroy. In 1877 he was appointed British commissioner of the Egyptian public debt office which had been set up to deal with the liabilities of the khedive Ismail. Baring's ability in financial administration quickly won him a dominant place on the board, and when in 1879 the Ottoman sultan deposed Ismail, Baring became the British controller general in the Anglo-French dual control. In 1880 he returned to India as financial member on the viceroy's council, remaining there until 1883. He proved a wise financier during a period of economic stringency and was knighted for his work.

After the defeat of the nationalist rising under Arabi Pasha in 1882, Egypt was occupied by the British, and Sir Evelyn Baring returned as British agent and consul general with plenipotentiary and diplomatic rank. Egypt was still dislocated by the revolt, while in the Sudan the mahdist rebellion was gaining momentum. So great had been the losses in men and equipment there that Baring felt the tottering Egyptian finances could not bear any further strain. He advised the abandonment by Egypt of all its Sudanese possessions except the towns of Wadi Halfa and Sawakin. The British government shared his views, and the policy of abandonment, much criticized in Great Britain and Egypt, was forced on the ministry of Mohammed Sharif Pasha which resigned in protest in Jan. 1884. The British government proposed the appointment of Maj. Gen. C. G. Gordon to superintend the evacuation of the

Egyptian garrisons. Baring, who questioned Gordon's suitability for this task, hesitated, but in view of the strength of popular feeling in Great Britain, reluctantly consented to the appointment against what he afterward felt to have been his better judgment.

With the evacuation of the Sudan completed, Baring resumed the reorganization of the Egyptian government services and in 1885, against opposition from the bondholders, obtained a loan for irrigation. Gradually his prudent handling of the Egyptian economy began to show a positive result and in 1889 the budget yielded a surplus. He now overhauled the railways, the administration of justice and state education. In his relations with the Egyptian ministers there was little question of consultation; his suggestions had the force of commands. He was raised to the peerage as Baron Cromer in 1892. The death in 1892 of the khedive Mohammed Tewfik with whom he had worked well, and the succession of the young Abbas Hilmi, who not unnaturally chafed under Cromer's tutelage, complicated his work.

The crushing defeat of an Italian army by the Abyssinians at Aduwa in March 1896 and the advance of Belgian and French expeditions toward the Nile suggested that the time was opportune for an Egyptian reoccupation of the Sudan. Dongola was occupied in Sept. 1896, and on Sept. 2, 1898, an Anglo-Egyptian force under Sir Horatio Herbert (afterward Lord) Kitchener broke the mahdist power at the battle of Omdurman. Great Britain, which had contributed substantially to the reconquest of the Sudan, demanded a share in its administration. The former Egyptian possession was placed under an Anglo-Egyptian condominium, devised by Cromer, which not only excluded the capitulations (*q.v.*) and the presence of foreign consular agents, but also denied to Egypt any real partnership in the joint government. The signature of the condominium agreement of 1899 by Cromer and the Egyptian prime minister, Butrus Ghali Pasha, was resented in Egypt. Cromer was created a viscount in 1899 and an earl in 1901. He took a leading part in the negotiations which led to the Anglo-French settlement of 1904 whereby France gave Great Britain a free hand in Egypt, and in the dispute with Turkey over Sinai in 1906.

Cromer's outstanding ability, his forceful character and his pre-eminent position in Egypt inevitably made him a controversial figure. While he enjoyed the friendship of prominent Egyptians such as Sheikh Mohammed Abduh, the great reformer, he failed to come to terms with the new generation of Egyptians who blamed him for withholding political reforms and neglecting education. But if he diverted the bulk of the available revenue to railways, irrigation and agriculture, he did so from a deep conviction that economic and social progress must come before the political and cultural wants of the intelligentsia whom in any case he distrusted. It is significant of his attitude that, while he was at pains to study Turkish, the language of the ruling elite, he did not consider it necessary or even advisable to learn Arabic, the language of the people. He was therefore out of touch with the Egyptian middle class from which most of the younger nationalist leaders were drawn.

In June 1906 a British officer was killed in a fracas with Egyptian villagers at Dinshaway during a pigeon shoot. The heavy sentences imposed by the judges disturbed Egyptian public opinion and, though Cromer was abroad at the time and had nothing to do with the trial, popular indignation made him the scapegoat. The widening rift between the British representative and articulate Egyptian opinion persuaded Sir Henry Campbell-Bannerman's ministry to adopt a more accommodating policy in Egypt. Cromer, overworked and exhausted, resigned in 1907 and was succeeded by Sir Eldon Gorst. He spent his retirement in literary pursuits and took some part in politics as leader of the free-trade wing of the Unionist party. In 1916 he presided over the Dardanelles commission, but the strain was too great and after one of the meetings he collapsed. He died in London on Jan. 29, 1917.

Cromer's published works include *Modern Egypt*, 2 vol. (1909), a defense of his Egyptian mission, and *Abbas II* (1915), a polemical biography. His annual reports on Egypt, 1884–1906, present an official account of his stewardship. See EGYPT: *History*.

See Lord Zetland, *Lord Cromer* (1932).

(R. L. HL.)

**CROMER**, an urban district and seaside resort of Norfolk, Eng., lies 25 mi. N. of Norwich by road. Pop. (1961) 4,895. The

town is near the end of the Cromer ridge, but the high yellow-brown cliffs on which it stands are being rapidly washed away into sandy beaches, revealing signs of prehistoric man. About 2.5 mi. inland is a Roman camp. The fine 14th century church of St. Peter and St. Paul has a lofty tower (160 ft.) that once served as a lighthouse, and a window designed by Sir Edward Burne-Jones. Cromer is a coast guard and lifeboat station with a lighthouse.

**CROMPTON, SAMUEL** (1753–1827), English inventor of the spinning mule, was born on Dec. 3, 1753, at Firwood near Bolton, Lancashire. From an early age he worked about the farm and spun cotton at Hall-i'th'-Wood, to which his family had removed. The defects of the spinning jenny inspired him with the idea of devising something better, and for five or six years the effort absorbed all his spare time and money, including what he earned by playing the violin at the Bolton theatre. About 1779 he succeeded in producing a machine which, by simultaneously drawing out and twisting the cotton roving fed into it, reproduced mechanically the actions of hand spinning and enabled yarn of the finest quality to be made. It was known as the muslin wheel or the Hall-i'th'-Wood wheel, and later was called the mule because it was a cross between Richard Arkwright's spinning machine and James Hargreaves' spinning jenny; it combined the drafting rollers of the one with the traveling carriage of the other. Unlike the jenny, however, the spindles were mounted on the carriage but the roving creel and drafting rollers were fixed.

After Crompton's marriage in 1780 a demand arose for the yarn which he made at Hall-i'th'-Wood, but he could not afford to take out a patent. He therefore decided to reveal the secret of his machine on the promise of a number of manufacturers to pay him for its use, but all he received was about £60. He then resumed spinning on his own account, but with indifferent success. In 1800 a sum of about £500 was raised for his benefit by subscription, and in 1812, when there were already at least 360 mills using 4,600,000 mule spindles, parliament allowed him £5,000. With this money he embarked in business, first as a bleacher and then as a cotton merchant and spinner, but without success. In 1824 friends bought him an annuity of £63. Crompton died at Bolton on June 26, 1827.

See G. J. French, *The Life and Times of Samuel Crompton* (1859); H. C. Cameron, *Samuel Crompton* (1951). (K. R. G.)

**CROMWELL, HENRY** (1628–1674), fourth son of Oliver Cromwell and the ruler of Ireland during the Protectorate, was born at Huntingdon on Jan. 20, 1628, and educated at Felsted school. He served under his father in the latter part of the first phase of the Civil War. In 1650 he took some troops to assist Oliver in Ireland and was one of the Irish representatives in the Nominated (or Barebone's) parliament of 1653. In Aug. 1654 he was appointed major general of the forces in Ireland and in December was made a member of the Irish council of state. On the departure for England of the lord deputy, Charles Fleetwood, in Sept. 1655, Henry was left for practical purposes the ruler of Ireland although he was given the title of lord deputy only in Nov. 1657. He had no voice in Irish policy, but his enforcement of the Cromwellian settlement was moderate and successful. Disapproving strongly of the excessive power in the hands of the army leaders, especially the Anabaptists, he diverged from Fleetwood's policy in protecting the interests of the English settlers and in holding the scales evenly between the different Protestant sects. By strict economy he overcame the financial problems of government, and successfully managed the reduction of the army in Ireland despite several months' arrears of pay. The earl of Clarendon attests Henry's undoubted popularity in Ireland.

On the succession of Richard Cromwell to the office of protector at his father's death (1658), Henry, although appointed lieutenant and governor general of Ireland, was reluctant to remain there. Having rejected proposals to assist in the restoration of Charles II, he was recalled to England in June 1659 just after his brother's fall. He resigned office at once, and although he lost some property at the Restoration, he was allowed to keep the estate he had bought in Ireland. His last years were passed at Spinney abbey in Cambridgeshire, where he died on March 23, 1674. In 1653 he married Elizabeth (d. 1687), daughter of Sir Francis Russell,

and left five sons and one daughter.

See R. W. Ramsey, *Henry Cromwell* (1933).

**CROMWELL, OLIVER** (1599–1658), lord protector of the Commonwealth of England, Scotland and Ireland from 1653 to 1658, was born at Huntingdon on April 25, 1599, the second son of Robert Cromwell and Elizabeth Steward. Oliver's paternal great-great-great-grandfather, Morgan Williams, is said to have belonged to a respectable Glamorgan family and to have accompanied King Henry VII from Wales. Morgan's son married Katherine Cromwell, whose brother Thomas became Henry VIII's chief minister. Consequently the family name was changed from Williams to Cromwell. Oliver's father, being a younger son, had a modest income, but at one time served as a member of parliament and held important local offices in Huntingdonshire.

**Early Years.**—Oliver Cromwell was educated at the Huntingdon free school and at Sidney Sussex college, Cambridge. He left Cambridge when he was 18, possibly because of his father's death (1617), and at 21 married Elizabeth, daughter of Sir James Bouchier, an Essex merchant. Both at school and at Sidney Sussex, which is said to have been a "nursery of Puritans," Cromwell imbibed the Puritan approach to life, but his "conversion" did not take place until he was about 28, a practising farmer and the father of five children. Although he later wrote: "You know what my manner of life hath been . . . I was a chief, the chief of sinners," there is no evidence, except much later stories, for supposing that in his youth he was guilty of anything more than high spirits. Essentially he was an outdoor man, fond of riding and sport.

In the 1620s Cromwell must have been in straitened circumstances, because two-thirds of the income of his father's estate had to go to Oliver's mother, but an uncle, Richard Cromwell, left him a little property in 1628 and he later received a more substantial inheritance from his mother's brother Thomas Steward. It was because of this that in 1636 Oliver and his family went to live at Ely in Cambridgeshire, having previously farmed near Huntingdon and St. Ives. At Ely he took a large part in local affairs. Already in 1628 he had been elected member of parliament for the borough of Huntingdon, but after 1629 there were no parliaments for 11 years.

When, however, Charles I was compelled to call in turn the so-called Short and Long parliaments in 1640, Oliver Cromwell was elected for the borough of Cambridge. He was then aged 41, a reasonably successful farmer with some experience of administration but no real training as a soldier.

**Parliamentary Opposition.**—The only speech that Cromwell is known to have made in the house of commons in 1628–29 was when he took part in an attack on the bishops. In the parliaments of 1640 many of his friends and relations were members and he undoubtedly belonged to the group that supported John Pym and John Hampden in their vehement criticism of the king's policies. Cromwell was fairly prominent in the early months of the Long parliament, speaking in several debates and serving on various committees. He was particularly critical of "innovations," by which he meant any form of ritualism, in the Church of England, and was soon to become a leader of the "root and branch" party; i.e., those who wanted to abolish the archbishops, bishops and other officers of the existing church hierarchy. He is not known to have taken any part in the debates on the earl of Strafford's attainder, but he moved the second reading of a bill for annual parliaments. He acquired some proficiency as an orator, but is said to have had a "sharp and untuneable" voice.

On the whole, religious questions took a secondary place in the first year of the Long parliament and Cromwell expressed concern that so little had been achieved in the matter of reform. The "root and branch" bill met with resistance and its opponents—the nucleus of the future royalist party—showed their unwillingness to strip the king of all his ancient prerogative powers during the prolonged debate on the Grand Remonstrance (Nov. 1641). After the Remonstrance had been carried by only 11 votes Cromwell is said to have told Viscount Falkland, a fellow member that if it had been rejected "he would have sold all he had the next morning and never seen England any more." This is the only basis

for a story that Oliver Cromwell once thought of settling in the new world.

### MILITARY CAREER

**The Civil War: 1642-43.**—In Jan. 1642, after the king's unsuccessful attempt to arrest five members of parliament for treason, Cromwell moved that a committee should be appointed to consider means of putting the kingdom in a state of defense (that is, against the king). In March he was concerned with Ireland, where rebellion had broken out the previous autumn, and subscribed £500 to buy land there as a contribution to a war chest. He served during the summer on a committee whose business was to prevent troops being recruited for the king in Yorkshire, and then on another committee for raising military and naval forces for parliament. In Aug. 1642, after the king had rejected parliament's final terms for a settlement, Cromwell rode down to his constituency to prevent plate, money, horses or arms being sent from the university to the king. He seized the castle, impounded much of the college plate and disarmed the local residents. By his prompt action he secured Cambridgeshire for the parliamentary side.

On Sept. 13, 1642, Oliver Cromwell received orders to muster a troop of cavalry which he had raised in Huntingdonshire and Cambridgeshire and it is presumed that this force joined the parliamentary army in the midlands. Cromwell seems to have arrived late at the battle of Edgehill (Oct. 23) and then to have withdrawn on London with the rest of the army. Later his troop returned to East Anglia and he was appointed a member of both the Eastern and the Midland associations. Cromwell, who was promoted from captain to colonel in Feb. 1643, then concentrated on training a double cavalry regiment of 14 troops (later known as the "Ironsides"). He laid great stress on training and morale. Soon after the setback at Edgehill he told his cousin John Hampden, "You must get men of a spirit, a spirit that is likely to go on as far as gentlemen will go or else I am sure that you will be beaten still." He insisted upon having "honest and religious men" in his regiment and tried to ensure that they received prompt pay and adequate clothing, but both as colonel and later as general he believed in rigorous discipline.

During 1643 Cromwell and his regiment were busy in the eastern counties. He wanted not only to secure them as a base for parliament, but by taking Newark in Nottinghamshire to increase the pressure upon the royalists in Yorkshire and cut them off from the king's headquarters at Oxford. His first clash with the enemy was at Grantham, south of Newark, on May 13 when his cavalry charged "at a pretty round trot," killed 100 and took 45 prisoners. His superior officers were, however, unwilling to attack Newark and by midsummer almost the whole of Yorkshire had been lost to the royalists who sent a force south to attack Peterborough. In the cavalry fight at Gainsborough (July 28) Cromwell reformed his men in a moment of crisis in the face of an unbeaten foe. He was commended for his "discretion and valour" and at the same time was appointed governor of Ely. When the parliamentary offensive was resumed in Lincolnshire Cromwell commanded the vanguard at the battle of Winceby (Oct. 11), where his horse was killed under him as he led a downhill charge. During the later part of this campaign he met Sir Thomas Fairfax, whose abilities he respected, but he thought poorly of others of his fellow officers who he did not believe had their hearts in the war.

**"The Great Independent."**—In 1644 parliament appointed Edward Montagu, earl of Manchester—the richest magnate in Cromwell's native county of Huntingdonshire—to take command of the new army of the Eastern association. Cromwell became his second-in-command with the rank of lieutenant general; in fewer than two years, though he was no more than an amateur, his powers of leadership and his natural skill as a cavalry officer had moved him far up the military ladder. Manchester described him as "a very wise and active head, universally well loved as religious and stout" though "a known Independent and favourer of the sects." Cromwell's reputation as "the great Independent"—that is, one believing in the right of the individual Christian congregation to choose its own ministers—was, in fact, already established.

A Calvinist and a fatalist, he tried to interpret God's will for himself. Providence, he thought, showed the way by the nature of events. His own regiment, even his original cavalry troop, was reckoned by him to be a "church" moved by the spirit of God. Thus while he was opposed to the Anglican ecclesiastical hierarchy and to all ritual services and ceremonies, he was equally anxious to avoid fastening a rigid Presbyterian system of a Scottish pattern upon the English Puritan congregations. Consequently Cromwell was reluctant to accept the alliance concluded by parliament (1643) with the Scottish covenanters. He agreed, however, to serve on the Committee of Both Kingdoms, which subsequently became responsible for the direction of the war. With the death of John Pym at the end of 1643 and the failure of the earl of Essex as commander in chief, Cromwell was becoming recognized as one of the outstanding Puritan military leaders. He enhanced his reputation during the campaign of 1644.

**Campaign of 1644.**—At the beginning of 1644 Cromwell carried out harassing operations between Cambridge and Oxford. It was at this time that the second of his four sons, Capt. Oliver Cromwell, died; his eldest, Robert, had died before the war. Soon after, Cromwell had a quarrel with Manchester's third-in-command, Maj. Gen. Lawrence Crawford, a Scotsman whom he accused of punishing junior officers merely for their religious opinions. Most of Manchester's army were Independents or sectarians who looked to Cromwell to protect their freedom of conscience. After acting as a covering force while Manchester stormed Lincoln in May, Cromwell and his cavalry joined the forces besieging York in June and on July 2 formed the left wing at the battle of Marston Moor (*q.v.*) where the king's army suffered its first major defeat of the war. Cromwell and Fairfax, supported by the Scots under David Leslie (afterward Lord Newark), shared the honours of the battle because two of the higher commanders fled the field believing all was lost. The victory was not followed up. Manchester returned to Lincoln and remained inactive for a month; he refused either to move against Prince Rupert, who was in northwest England, or to besiege Newark. Cromwell grew restless; he quarreled with Crawford and was reprimanded by Manchester. He succeeded, however, in inducing parliament to instruct the assembly of divines, which was then considering the future organization of the national religion, to provide an "accommodation" for "tender consciences," and he received the thanks of the house of commons for his services at Marston Moor. In October he took part in the second battle of Newbury, where unfavourable ground prevented his cavalry from making much impression on the royalist defenses. Though he pursued the king toward Oxford, the enemy safely escaped the grip of a larger army.

**The New Model Army.**—Disgusted by these failures, Cromwell resumed his seat in the house of commons in Nov. 1644 and delivered an attack upon the earl of Manchester. Manchester then declared in the house of lords that Cromwell was a "factious and somewhat inert officer." The Presbyterian leaders even proposed to bring Cromwell to trial as an "incendiary." Thus to military differences were added religious animosities. The charges against Cromwell were not upheld, and he now made the statesmanlike proposal that all should apply themselves to winning the war. He agreed to a suggestion that henceforward no officers who were members of either house of parliament should be allowed to hold any office or command and that a new army should be formed under an impartial nonpolitical general. So the "New Model army" was set up, absorbing the army of the Eastern association; Sir Thomas Fairfax was appointed commander in chief and Cromwell prepared to resign his commission and retire from active warfare. However, the commander in chief was allowed to make new appointments subject to the approval of parliament, and although, after two extensions of his command, Cromwell returned to Ely ready to give up his commission, the post of lieutenant general in the New Model army was significantly left vacant by Fairfax. It seems obvious that Fairfax recognized Cromwell's extraordinary gifts and popularity as a soldier and was determined to re-employ him. At any rate on the eve of the critical battle of Naseby (*q.v.*; June 14, 1645) Fairfax ordered Cromwell to join his army as lieutenant general, even though the house of lords

had not confirmed the appointment. In his dispatch written after the battle Cromwell gave credit to the new commander in chief and his men as well as to God and reminded the house of commons that "he that ventures his life for the liberty of his country" deserved to be protected in his own liberties, including liberty of conscience.

Cromwell now accompanied Fairfax to the southwest and took part in the battle of Langport (July 10) where a royalist army under Lord Goring was beaten. Then he helped to soothe the "club-men" of Dorset who were anxious to keep both the contending parties out of their county. After being present at the siege of Bristol, he moved into Wiltshire and Hampshire where he besieged Basing house, a royalist stronghold belonging to the Roman Catholic marquess of Winchester. After the garrison, though hopelessly cut off, had refused to yield, the place was stormed. When a breach had been blown no quarter was given and 300 of the defenders massacred. As a result of this severity another royalist strong point surrendered without a fight. Cromwell, whose discipline throughout the campaign was strict, could no doubt have prevented the violence and plundering at Basing house if he had wished. This was to be the pattern of his later conduct at Drogheda in Ireland. He joined Fairfax at Exeter late in Oct. 1645 and winter quarters were established in the southwest. Cromwell's commission was renewed and he was awarded £2,500 a year secured on confiscated royalist estates. In 1646 he took part in the final stages of the siege of Oxford, which brought the first phase of the Civil War to a close. Then he settled with his family in London and became active in the house of commons.

**Quarrels of Army and Parliament.**—The problems before the victorious parliamentarians were how to reach a constitutional agreement with the king, how to disband the army, how to suppress the continuing rebellion in Ireland and how to frame a satisfactory religious settlement. Cromwell was anxious to come to an understanding with the king who, once the Scottish army had left England early in 1647, was a prisoner. Cromwell wanted a fair deal for the army which had served parliament so faithfully and successfully. He recognized the importance of restoring order in Ireland and he worked ceaselessly for a religious settlement which, while it abolished the bishops and the Book of Common Prayer, would allow freedom of conscience for all Christians within a general framework of order. Most of the remaining members of the commons wanted to demobilize the army as quickly as possible and to recruit volunteers to serve in Ireland. Moreover, there was in the house a predominant Presbyterian element, antagonistic to the sects, which ignored Cromwell's appeals for liberty of conscience. Cromwell expressed his disgust. He told Fairfax that "never were the spirits of men more embittered than now." Although at the request of parliament he tried to persuade the soldiers to accept a compromise on the terms of their demobilization, he found he could not induce them to volunteer for Ireland. As both sides remained adamant, he decided after prolonged hesitations to throw in his lot with the army. He left London and arrived at the army headquarters at Newmarket at the beginning of June. He expressed his approval of the action of Cornet George Joyce, an officer in Fairfax's life guard, in seizing the person of the king and bringing him to the army, though it is doubtful that he had ordered Joyce to do so and he certainly denied that he had given him instructions to move the king from his previous place of captivity.

The quarrel between parliament and the army thus reached a climax. The army moved from Newmarket toward London and compelled the Presbyterian leaders in parliament to flee, but afterward it withdrew. Meanwhile Cromwell and his son-in-law Henry Ireton met the king and drew up a plan for a constitutional settlement, which they hoped would be acceptable both to him and to parliament. However, the entire political situation deteriorated. A mob invaded the house of commons and forced Cromwell's friends in turn to flee, while the Presbyterian leaders came back. In August Cromwell rode with his cavalry into London and after restoring order there began to busy himself in trying to conciliate the different parties. Now not only were the Presbyterians and Independents at loggerheads, but the army itself was divided between

those who wanted a conservative constitutional arrangement with the king and the extremists in the rank and file who advocated a democratic system and the abolition of the monarchy and the house of lords. These latter proposals, put forward by a party known as the Levellers, were debated in the army in Oct.-Nov. 1647. In vain Cromwell, who took the chair at these meetings (held at Putney), strove for unity, concord and compromise. Deep passions were aroused. The king took the opportunity to escape from the control of the army and fled to the Isle of Wight, hoping to regain his throne while his enemies quarreled with one another. Cromwell was bitterly disappointed. He felt it was hopeless to go on bargaining with Charles. On Jan. 3, 1648, he told the commons that the king was "an obstinate man whose heart God had hardened." But all through the winter he struggled to formulate an acceptable settlement. He contemplated replacing Charles I on the throne by his eldest son. The king, meanwhile had reached a secret agreement with a party in Scotland to fight on his behalf, and at the same time he inspired a fresh royalist rising throughout England and Wales.

**The Civil War: Second Phase.**—Fairfax ordered Cromwell to go to south Wales. He concentrated his force at Gloucester and then marched to Pembroke castle where the governor and garrison had changed sides. The siege lasted nearly seven weeks because the castle was massively fortified and had to be starved into surrender (July 11, 1648). Cromwell then made a forced march north to cut off the Scottish invasion. His infantry covered 260 mi. from Pembroke to Pontefract in Yorkshire in 27 days. On Aug. 16, Cromwell having joined Maj. Gen. John Lambert at Knaresborough, a council of war was held and the decision taken to attack at Preston, even though the parliamentary army of 9,000 men was known to be inferior in number to the Scots. In fact Cromwell encountered only the northern (English) royalists at Preston and destroyed them in an infantry contest. Then he pursued the Scots toward Warrington. At Winwick pass the Scottish infantry was beaten and 6,000 prisoners taken. Finally the Scottish commander, the duke of Hamilton, and his cavalry were forced to surrender (Aug. 25) to Lambert in Staffordshire. Thus the invasion was crushed and the Scots and northern royalists defeated piecemeal. It was Cromwell's greatest triumph as an independent commander. He now turned to clear the north of England and then, on Sept. 21, crossed into Scotland. He entered Edinburgh on Oct. 4, came to terms with the marquess of Argyll and left behind two regiments to lend him support against Hamilton's party. Berwick and Carlisle surrendered to the English and a fortnight later Cromwell was back in Yorkshire to supervise the siege of Pontefract.

**Execution of Charles I.**—Meanwhile in the south the fighting came to an end. The king still hoped that dissensions among his enemies would enable him to make good terms for his restoration to the throne and negotiations were continuing between him and parliamentary commissioners in the Isle of Wight. However, the army was angry at the renewal of the war and demands were made for the king's deposition and trial. Cromwell himself thought that the royalists had acted shamefully in breaking their promise not to fight again and in inviting the Scottish invasion. He said that to negotiate further with Charles I was to meddle with "an accursed thing." Both the northern and southern sections of the army demanded that "impartial justice" should be done to "all offenders," and eventually Cromwell informed Fairfax that he agreed with this view. He felt that the army had been chosen by God to oppose and fight the king and that providence now ordained his trial as a criminal. These conclusions he reached slowly and painfully in Yorkshire. On Dec. 7, 1648, having been recalled by Fairfax, he returned to London where he approved the purge of the house of commons by the army. He still seems to have hesitated, perhaps hoping against hope for a last-minute compromise with the king. Charles, now brought to Windsor as the prisoner of the army, refused all concessions and was determined on martyrdom. Cromwell, who was one of the 135 commissioners appointed to try the king, had finally made up his mind that Charles must die and, according to stories told after the Restoration, was active in promoting the verdict of death and inducing his fellow commission-

ers to sign the death warrant. Cromwell regarded the execution of the king (Jan. 30, 1649) as an act of justice for his crimes, particularly in engineering the renewal of the war, and there is no solid evidence that he ever repented of it.

**Cromwell in Ireland.**—Cromwell was chosen the first chairman of the council of state—the organ of the purged parliament that governed England as a republic. The Levellers were disappointed at this oligarchical form of government and John Lilburne, their leader, incited mutiny and threatened to burn down Whitehall palace. Lilburne was imprisoned and Fairfax and Cromwell together suppressed the mutiny, but a threat to the security of the new republic arose in Scotland and Ireland. Cromwell agreed in June 1649 to lead a force to Ireland, provided that adequate funds and equipment were guaranteed, and he landed at Dublin on Aug. 13, as lord lieutenant and commander in chief. The royalist army had suffered a defeat 11 days earlier and the royalist lord lieutenant retired his remaining best troops to the fortified town of Drogheda, north of Dublin. Cromwell stormed the town on Sept. 10–11, when a large part of the garrison was deliberately put to the sword because it had refused quarter and had defended the breach in the wall. Cromwell was justified in inflicting this punishment by the current laws of war, but he himself wrote afterward that “this was a righteous judgment of God upon these barbarous wretches, who have imbrued their hands in so much innocent blood, and that it will tend to prevent effusion of blood for the future; which are the satisfactory grounds for such actions, which otherwise cannot but work remorse and regret.” The massacre struck terror into the Irish, who surrendered several fortresses without fighting. Wexford resisted on Oct. 11, and there was again great slaughter after the first assault had been repulsed, although there it was accidental rather than intentional. In November Waterford also resisted strongly. By the end of 1649 much of the coast of Ireland was in Cromwell’s hands. He then moved his army inland and took a number of fortresses in Munster and the Irish capital of Kilkenny. After the surrender of Clonmel early in May 1650, he returned to England, having been recalled because of a new danger from Scotland.

**Cromwell in Scotland.**—The Scottish covenanters had declared Charles II to be king and refused to recognize the English republic. The English parliament retorted by sending an army under Cromwell to invade Scotland. Since Fairfax had refused to take this command, Cromwell became (June 26, 1650) by act of parliament captain general and commander in chief as well as retaining the title of lord lieutenant of Ireland. He entered Scotland on July 22 with an army of 10,500 foot and 5,500 horse. He spent a month in marching around Edinburgh and in fruitless skirmishes because the Scots refused to be drawn into a battle. He lost nearly a half of his army through sickness, ran short of supplies and finally led his men back to the port of Dunbar, east of Edinburgh, to await reinforcements. The Scots, under Leslie, had, however, outmaneuvered the English and by occupying a position 2 mi. S.W. of Dunbar on Doon hill had cut them off from their home bases. Therefore, when Leslie brought his men down from Doon hill on Sept. 2, Cromwell decided to surprise him by attack at dawn next day. The Scots repulsed the first English assault, but at the critical moment Cromwell threw in his reserve of one cavalry and three infantry regiments. The Scots, cramped in the centre and on their left wing, were almost annihilated. Next day Cromwell’s forces occupied Edinburgh (although the castle held out until Christmas Eve) and he then confronted the remaining Scots, who were well fortified in a position south of Stirling. In Feb. 1651 Cromwell was taken ill with malaria contracted in Ireland and it was not until June that active campaigning was resumed. He then sent Lambert across the Forth to turn the Scottish position. This accomplished, the bulk of the English army followed and threatened the Scots’ rear, and the Scots took the obvious course open to them and crossed the border into England.

Cromwell was not surprised by this countermove and felt confident of checking and then overtaking the invading army. Leaving Col. George Monck behind to secure Scotland, Cromwell sent ahead his cavalry and followed with the infantry into Yorkshire. While Charles II was reaching Worcester on Aug. 22, having

picked up fewer recruits on his way than he had hoped, Cromwell blocked the king’s further advance at Evesham. By dividing his forces he was able to attack Worcester from two sides. A bridge of boats was thrown across the river Severn south of the town and Cromwell in person led the way across. Charles II tried to break out of the city to the east, but Cromwell recrossed the river and rode at the head of a successful counterattack. He described the battle of Worcester (Sept. 3) as a “crowning victory.”

## LORD PROTECTOR

**End of the Rump Parliament.**—As commander in chief Cromwell lived, from the end of 1651 onward, in official residences at the Cockpit in Whitehall and at Hampton Court palace. He had been assigned an additional income out of more confiscated royalist estates and became a comparatively wealthy man. In 1652 he pressed for an amnesty to royalists, urged the reform of the law and wanted a new parliament to be elected under a fresh constitution. In Nov. 1651 the house of commons had agreed to have an election three years later, but Cromwell still felt unsatisfied and worked for the reform and strengthening of the republican government. The Anglo-Dutch naval war also disturbed him, as he did not care for fighting against fellow Protestants, but he did his duty as a commander and member of the council of state. Gradually antagonism sprang up between the army leaders and the civilian members of the Rump parliament who were freely accused of feathering their own nests at the republic’s expense. In April 1653, after all attempts at a compromise between the two sides had failed, Cromwell took a guard of soldiers and, having accused the members of injustices and corruption, forcibly dissolved the house of commons. In its place the council of the army selected 140 men from a list of names submitted by the congregational churches both to legislate and to direct the government. This assembly became known variously as the Little, Nominated or Barebone’s parliament and was afterward described by Cromwell as a tale of his own “wickedness and folly.” On Dec. 12 Lambert, after drawing up a new constitution known as the Instrument of Government (*q.v.*), engineered the dissolution of the Little parliament, which delivered up its powers to Cromwell from whom it had first received them.

**Lord Protector.**—According to the terms of the Instrument of Government, Cromwell became lord protector of the Commonwealth of England, Scotland and Ireland and was assisted in the execution of his duties by a council of state. Legislation was to be initiated or approved by a “freely elected” unicameral parliament which was required to sit for at least five months every three years. On Dec. 16, 1653, Cromwell took the oath as lord protector and on Sept. 3, 1654, addressed his first parliament. The freely elected protectorate parliament at once showed itself unwilling to accept the constitution that had been fastened on the country by the army’s leaders. Thereupon Cromwell, insisting that the constitution had received the implicit consent of the nation, told the members of the new parliament that they must accept the “fundamentals” of the new rule if they wished to keep their seats. Apart from 100 convinced republicans the members agreed to do so, but were still more concerned with rewriting the constitution than reforming the laws as desired by the protector. As soon as he could legitimately do so (Jan. 22, 1655), Cromwell dissolved parliament. By this time some royalists hoped to profit from the dissensions between the Cromwellians and the rest by planning an insurrection, which began the following March in Wiltshire. To maintain internal security Cromwell then instituted a system of regional government whereby the country was divided into 11 districts, each governed by a major general commanding police forces of horse militia. The system was financed by a 10% tax, or “decimation,” levied upon royalists. Soon afterward, the Dutch war having ended in April 1654, the Commonwealth government became involved in a war with Spain. The lord protector summoned a new parliament, which met in Sept. 1656, in order to raise money for this war.

The second protectorate parliament was, as far as possible, hand-picked by Cromwell’s officials. About 100 of its members were more or less committed Cromwellians and another 100 of Crom-

well's republican critics were forbidden to take their seats. The remaining members then approved the war with Spain and voted money for its continuation. Nevertheless, even this carefully packed assembly refused to approve the method of government through major generals. In order to try to establish a more permanent and acceptable constitutional system a number of Cromwell's civilian supporters and lawyers then proposed that he should assume the crown and become a constitutional king. In return for this "feather in his cap," as he called it, the protector was asked to agree to the setting up of a second house of parliament and to the commons in the future controlling its own election returns. These proposals were carefully considered by Cromwell, who accepted the arguments for returning to a method of government in tune with tradition and the common law of the land. Most of his friends in the army, however, fiercely objected to his becoming king and to the destruction of the republic. In May 1657 Cromwell finally refused the offer of the crown but agreed to a new constitution, which was known as the Humble Petition and Advice (*q.v.*). When the second protectorate parliament was recalled to approve the constitution, opposition in the commons became violent. On the one hand, the members who had been excluded by the army in 1656 resumed their seats; on the other, many of Cromwell's supporters could not sit because he had already nominated them for membership of the new upper house. The republican leaders in the commons refused to recognize this upper house and expressed their intention of sabotaging the new constitution. Within a fortnight Cromwell lost his temper, and in Feb. 1658 dissolved parliament. For the remainder of his life he ruled without a parliament, although it seems certain that he intended to summon one later in 1658.

#### ACHIEVEMENTS AND CHARACTER

**Cromwell's Foreign Policy.**—As the ruler of England Cromwell was more successful in the direction of foreign than of domestic affairs. The Dutch war was brought to an advantageous conclusion, the treaty of Westminster of April 1654 providing for the security of British commerce and respect for British naval supremacy in British waters. The Dutch also promised to abandon support for the royalists. Commercial treaties, all favourable to British trade, were concluded with Sweden, Denmark and Portugal. Once peace was established, so strong was the Commonwealth that its alliance was sought by the rival Catholic powers, France and Spain. Cromwell and his council of state hesitated between them. Eventually religious considerations swayed the decision. It was felt that the French Protestants could best be helped by an alliance with the milder French monarchy while the bigoted Spanish Catholic monarchy might be attacked from the sea as in Elizabethan times and part of the Spanish empire captured in the name of Protestantism as well as of trade. Even before the war was officially declared the protectorate government sent a naval expedition to the Spanish Indies, which secured Jamaica. Another expedition under Gen. Robert Blake advertised British naval power in the Mediterranean. War with Spain began in the autumn of 1655. A mainly commercial treaty was concluded with France at about the same time and was followed in March 1657 by an Anglo-French offensive military alliance. Cromwell promised to send an expeditionary force of 6,000 soldiers, as well as a fleet, to attack the Spaniards in the Low Countries. There the English soldiers fought with distinction and, in accordance with the terms of the alliance, the French reluctantly handed over the conquered ports of Dunkirk and Mardyke to the English Commonwealth. Earlier in April 1657 Blake had defeated a Spanish fleet at the battle of Santa Cruz. In Feb. 1658 Cromwell's ambassador mediated a peace between Sweden and Denmark, although before his death that war broke out again in the Baltic. Relations between the English and Dutch remained uneasy. Cromwell's grand schemes for a European Protestant alliance were never realized, but British prestige was nevertheless high during the protectorate.

**Cromwell's Domestic Policy.**—Most of Cromwell's domestic legislation was repealed at the Restoration. Nevertheless, important reforms of the law—such as the decision that in the future the language of the common-law courts should be English—were

retained. However, attempts to reform the chancery law and to reduce the severity of the criminal code were resisted by lawyers and blunted by the intransigence of the members of Cromwell's parliaments. The policy of the navigation acts introduced to encourage British merchant shipping was confirmed and strengthened by the parliaments of Charles II. The legislative union of England, Scotland and Ireland, which formed part of the constitutional settlement of the protectorate and brought some material benefits to the Scots and Irish, was not continued at the Restoration. In his youth Cromwell had been a fanatical Puritan determined to destroy the bishops. As protector he showed himself increasingly tolerant and even liberal minded in his religious views. Although in 1648 parliament agreed to establish Presbyterianism as the national religion of England, Cromwell saw to it that complete freedom of worship was allowed to all Puritan sects. He tried to protect Quakers and even Unitarians from the full fury of his parliaments and permitted some Anglican and Roman Catholic services to be held in private houses.

**Family and Characteristics.**—Before he died Oliver Cromwell nominated his eldest surviving son, Richard, to succeed him as protector in accordance with the terms of the Humble Petition and Advice. He was also survived by another son, Henry, who rose to be lord lieutenant of Ireland, and by three daughters—Bridget, who was married first to Henry Ireton and then to Charles Fleetwood; Mary, married to Lord Fauconberg; and Frances, married to Robert Rich, grandson of the 2nd earl of Warwick. Another daughter, Elizabeth (married to John Claypole), who was said to have been Cromwell's favourite, predeceased him by four weeks. His widow lived in retirement until her death in 1672. Oliver Cromwell died of malaria in London on Sept. 3, 1658, and after a big public funeral was buried in Westminster abbey. At the Restoration his bones were hung up at Tyburn gallows and his severed head placed on a pole on top of Westminster hall.

Oliver Cromwell was just under six feet tall with long hair and gray-blue eyes. Though a man of fierce passions, he was, except on the battlefield, slow in reaching decisions. He was a born leader and soldier. His hobbies included hunting, hawking and music, and he liked smoking and an occasional glass of wine. By nature he was neither cruel, tyrannical nor intolerant, but his fatalistic religion and the strictness of his military discipline have given posterity an impression of puritanical severity that is perhaps scarcely justified. See CIVIL WAR, ENGLISH; ENGLISH HISTORY. See also references under "Cromwell, Oliver" in the Index volume.

C. Lomas (1904); Maurice Ashley, *The Greatness of Oliver Cromwell* (1958). There are lives by S. R. Gardiner (1899), Sir Charles Firth (1900), Lord Morley (1900), John Buchan (1934) and Robert S. Paul (1955). For the military background, see T. S. Baldock, *Cromwell as a Soldier* (1899); Maurice Ashley, *Cromwell's Generals* (1954). (M. P. A.)

**CROMWELL, RALPH** (c. 1394–1456). 3rd Lord Cromwell, one of the wealthiest men of his time, was treasurer of England from 1433 to 1443. After a military career under Henry V he was appointed in 1422 to the council of regency for Henry VI and became chamberlain of the exchequer soon afterward. An associate of Henry Cardinal Beaufort, he lost his office when Beaufort suffered temporary eclipse in 1432. Both men justified themselves before the lords in parliament and returned to power after the intervention of John, duke of Bedford, in 1433. As treasurer Cromwell attempted reforms but was soon defeated by the impossible tangle of Lancastrian finances. He resigned when Beaufort retired in 1443, and soon joined the inchoate "Yorkist" group, leading the attack in 1449 upon William de la Pole, duke of Suffolk, Beaufort's successor in power. Cromwell was later denounced by Richard Neville, earl of Warwick, as instigator of the first battle of St. Albans (1455). But the Wars of the Roses had not really begun when Cromwell died, childless, on Jan. 4, 1456.

Cromwell's wealth was formidable, amassed through inheritance, through his marriage to Margaret, daughter of John, Lord Deincourt, through the acquisition and improvement of land, the spoils of office and government finance. A conservative modern

estimate, based on his accounts, assesses his net annual income from land alone at about £1,000 in 1429–30 and at over £2,000 in 1453–54; a less conservative contemporary thought his annual expenses came to £5,000. But he did not hoard. He built castles at Tattershall in Lincolnshire and at Wingfield in Derbyshire; he put up new buildings at Colley Weston, Northamptonshire, and founded a college at Tattershall. Lawsuits in land inherited or purchased added to his costs, and he was alleged "commonly" to ride to London with 120 horsemen.

See Lord Curzon and H. A. Tipping, *Tattershall Castle* (1929).

**CROMWELL, RICHARD** (1626–1712), lord protector of England, eldest surviving son of Oliver Cromwell and Elizabeth Bourchier, who unsuccessfully attempted to carry on his father's role as leader of the Commonwealth. Born on Oct. 4, 1626, he served in the parliamentary army and in 1647 was admitted a member of Lincoln's Inn. In 1649 he married Dorothy, daughter of Richard Mayor or Major, of Hursley in Hampshire. He represented Hampshire in the parliament of 1654 and Cambridge university in that of 1656, and in Nov. 1655 was appointed one of the council of trade. He was not brought forward by his father or prepared in any way for his future great position, and lived in the country occupied with field sports until after the institution of the second protectorate in 1657 and the recognition of Oliver's right to name his successor. On July 18 he succeeded his father as chancellor of the University of Oxford; on Dec. 31 he was made a member of the council of state and about the same time obtained a regiment and a seat in Cromwell's house of lords. He was received generally as his father's successor and was nominated by him as such on his deathbed. He was proclaimed on Sept. 3, 1658. Richard not being "general of the army as his father was," his elevation was distasteful to the officers, who desired the appointment of a commander in chief from among themselves, a request refused by Richard. The officers in the council, moreover, showed jealousy of the civil members, and to settle these difficulties and to provide money a parliament was summoned on Jan. 27, 1659, which declared Richard protector, and incurred the hostility of the army by severely criticizing the arbitrary military government of Oliver's last two years and by impeaching one of the major generals. A council of the army accordingly established itself in opposition to the parliament and demanded on April 6 a justification and confirmation of former proceedings, to which the parliament replied by forbidding meetings of the army council without the permission of the protector and insisting that all officers should take an oath not to disturb the proceedings in parliament. The army now broke into open rebellion and assembled at St. James's. Richard was completely in their power; he identified himself with their cause and the same night dissolved the parliament. The Long parliament (which reassembled on May 7) and the heads of the army came to an agreement to effect his dismissal and in the subsequent events Richard appears to have played a purely passive part, refusing to make any attempt to keep his power or to forward a restoration of the monarchy. On May 25 his submission was communicated to the house. He retired into private life, heavily burdened with debts incurred during his tenure of office and narrowly escaping arrest even before he left Whitehall. In the summer of 1660 he went to France, where he lived in seclusion under the name of John Clarke, subsequently going elsewhere, either (the accounts differ) to Spain, to Italy or to Geneva. He was long regarded by the government as a dangerous person, and in 1671 a strict search was made for him but without avail. He returned to England about 1680 and lived at Cheshunt, in the house of Sergeant Pengelly, where he died on July 12, 1712, being buried at Hursley, Hampshire. According to Mrs. John Hutchinson in her *Life of Colonel Hutchinson* (1885), Cromwell was "gentle and virtuous but a peasant in his nature and became not greatness."

See R. W. Ramsey, *Richard Cromwell, Protector of England* (1935). (P. C. Y.)

**CROMWELL, THOMAS**, EARL OF ESSEX (1485?–1540), English statesman, architect of the Reformation and the minister responsible for effecting the dissolution of the monasteries. He was born in Putney, the son (probably) of Walter Cromwell, alias Smyth, a brewer, blacksmith and fuller. His early life is obscure,

neither the older legends (preserved in John Foxe's *Book of Martyrs*) nor later researches being very reliable on this point. It appears that he went abroad at an early age and spent some time in Italy, possibly serving there as a soldier in the French army and certainly engaged in getting to know the world. For several years after 1510 he was resident at Middelburg and Antwerp in the Low Countries; he seems to have been closely connected with the London Merchant Adventurers. By 1520 he had entered Thomas Cardinal Wolsey's service and from that time his career is well documented. In the first place he seems to have added legal training to his commercial experiences. In 1524 he was admitted a member of Gray's Inn and for about eight years he acted as the cardinal's solicitor. He continued his trading activities and may have acted as a moneylender. In 1523 he sat in parliament. Wolsey employed him in 1525 about the dissolution of some lesser monasteries whose property was used to endow the cardinal's colleges at Ipswich and Oxford; in this work he earned a good deal of dislike. However, the cardinal continued to favour him and Cromwell soon occupied something like the position of his man of business and confidential adviser.

Thus, when Wolsey fell into disgrace in 1529, Cromwell was faced with a difficult problem. His enemies were trying to involve him in his master's fate and he, therefore, decided on a characteristic and bold stroke. He determined to bring himself to the king's notice and to do this by entering the parliament that met in Nov. 1529. Utilizing his private connections but also obtaining slight encouragement from Henry VIII, he got a seat at Taunton at the last moment. For nearly three years he worked his way up in the royal favour, entering Henry's service early in 1530, being sworn of the council toward the end of that year and reaching the inner circle of confidential advisers a year later. All the time he was establishing his ascendancy in the house of commons. In 1532 he at last obtained office (that of master of the jewels); to this he added others, of which the most important were principal secretary and master of the rolls in 1534 and lord privy seal in 1536. The last office was combined with a peerage, and he took the title of Lord Cromwell of Wimbledon.

**Cromwell and the Reformation.**—The question of Cromwell's part in the Henrician Reformation has caused much debate. At one time he was credited with supplying Henry with a complete plan as early as 1529; later it became usual to see in him nothing but the king's most competent executive agent. The truth seems to be that he was in no way in charge until early in 1532, taking over when the king's policy of forcing the pope to come to terms by bluster and blackmail had quite clearly proved a failure. It was, to all appearances, Cromwell who then came forward with a clear notion of how to achieve Henry's purpose without the pope. His policy consisted in making a reality of some large and vague claims to supreme power which Henry had uttered at intervals. He proposed to destroy Rome's power in England and to replace it by the royal supremacy in the church. He was behind the first attacks on the papacy (1532), the act against the payment of annates and the Supplication Against the Ordinaries, a protest used to secure the submission of the clergy to the king in matters of legislation. The second of these documents was devised by Cromwell on the basis of genuine complaints by the commons against church courts of which he had taken charge as early as 1529. In 1533 he secured the passage of the great Act in Restraint of Appeals to Rome whose preamble embodied his political theory. Thereafter he was in complete control of the government, though he remained careful to pretend to be acting on the king's authority. In 1534 he completed the erection of

BY COURTESY OF THE PRICK COLLECTION, NEW YORK CITY

THOMAS CROMWELL. PORTRAIT BY HANS HOLBEIN THE YOUNGER

the royal supremacy with the passing of the Act of Supremacy; the year after he turned to its exploitation. Political and financial reasons counseling an attack on the monasteries, he was appointed the king's vicar-general with powers to visit and reform all monastic institutions. An earlier survey (1535) established the details of all ecclesiastical property in England in the *Valor Ecclesiasticus*, a remarkable achievement of administrative efficiency. In the second half of 1535 Cromwell's agents visited the monasteries to collect evidence of corruption, worldliness and scandal, and (in theory) to amend these abuses. However, next year this evidence (which was not so much invented as highlighted) was used to justify the dissolution of all the smaller monasteries. Despite such difficulties as serious risings in the north, the task was carried out relentlessly. During 1537–40 the surrender of the greater houses was obtained by pressure and persuasion and by 1540 all monastic institutions had ceased to exist, their property being vested in the crown. Cromwell and other crown officials obtained valuable grants as rewards, but while the minister lived the new wealth was not squandered.

In 1536 Cromwell was also appointed the king's vicegerent in spirituals, that is, his deputy as head of the church. As such he presided in convocation and issued the Injunctions of 1536 and 1538 which began a cautious advance toward a Protestant Reformation by ordering that every parish should possess an English Bible, by attacking some excesses in the practice of pilgrimages and image worship, and by attempting a much-needed reform of the clergy. Cromwell's own religious views have been in much doubt. Certainly the old notion of his Protestant zeal will not stand up to examination but neither will the later view that he had no religion at all. Essentially his was a secular temper. He had had a most unusual training for a king's minister and his early life seems to have equipped him with a healthy amount of disillusionment and skepticism, but his character was essentially positive and he had a faith, even if it was not very ardent and liable to be subordinated to political considerations. As he once told some Lutheran envoys: on the whole he was of their mind in matters of religion, but "as the world now stood he would believe even as his master, the king, believed." Nevertheless, he came to be firmly associated with a radical policy of reform and Reformation. In the main this resulted from difficulties abroad. While hostility between France and Spain had prevented foreign intervention in the critical years 1533–36, there seemed a danger of an alliance against England after that date. Cromwell, whose forthright and clear-sighted temper was less well suited to the conduct of foreign affairs than Henry VIII's skilful opportunism, involved himself in projects of a Lutheran alliance distasteful to the king who wished to stand on Catholic orthodoxy. In 1539 the minister's enemies at home secured a triumph in the passage of the anti-Protestant Act of Six Articles, and though Cromwell recovered his ascendancy he then made the mistake of trying to force the king to his side by compelling him into marriage with Anne of Cleves. The king from the first hated his fourth wife and by Feb. 1540 it was clear that the alliance with the German princes which she represented was unnecessary. Thereafter Cromwell's fall came quickly. He fought back for a few months, being created earl of Essex and lord great chamberlain as late as April 1540, but early in June his enemies persuaded Henry that his vicegerent was a heretic and a traitor. He was arrested on June 10, condemned without a hearing by act of attainder and executed on July 28. His fall did not end the Reformation, but it marked the end of competent government and purposeful policy in Henry's reign; the king soon regretted that he had listened to the lies of Cromwell's foes.

**Achievements and Character.**—Although he conducted affairs for a bare eight years, Cromwell can lay claim to remarkable achievements. It was his mind and his conception of the state that underlay the revolution known as the Henrician Reformation. The basis of Cromwell's thought was the notion of the sovereign national state which in practice he established by the expulsion of the papacy. He was greatly interested in political theory, being well acquainted with the work of Marsilius of Padua and collecting around himself theorists and thinkers whom he employed to trans-

late ideas into formal plans. It seems improbable that he knew Machiavelli's writings, as was once alleged. As for his conception of the English state and monarchy, the old views which charged him with favouring despotism and wishing only to serve the royal will must be abandoned. His central idea was that of the supremacy and omnipotence of statute, or (as it came to be called) the legislative sovereignty of the king in parliament. In other words, he wished to establish unlimited sovereignty in the hands of a monarchy limited by dependence on consent. His work in parliament—managing elections, drafting statutes, piloting legislation—makes him the first of a long line of English parliamentary statesmen. He also showed himself aware of the need for providing practical management of a new kind. No minister before him and few after, exercised such pervasive influence over every detail of administration. More, he undertook a complete overhaul of the king's government, and here too he proved that he could seize on a great principle and apply it in detail. The administration which he took over was based on the principles of medieval government which centred upon the king and the men who surrounded him in his household. Cromwell began, and to a large extent carried through, a reconstruction which replaced this sort of "household administration" by a national administration divorced from the person of the king and dependent on civil service departments. This aspect of his work endured, through many reforms, until the great changes of the 19th century. In economic affairs he stood for the encouragement of the English cloth trade (which meant peace with Spain), tried to prevent the uncontrolled private exploitation of land and sponsored the first well-considered attempt to solve the problems of poverty and unemployment.

Cromwell's greatness as a constructive statesman cannot thus be in doubt. Of his character it is harder to speak with such certainty. He was entirely ruthless (though, since he lacked passion, he was not bloodthirsty like Henry VIII), concerned only with carrying through his plans and devastating to opposition. He enriched himself greatly, but it was noticed that he spent as freely as he got. His friends liked him very well, but of necessity a man of such outstanding revolutionary achievements had many more enemies who hated him devotedly. If he had a private life, almost nothing is known of it. His only son, Gregory, who showed no trace of his father's ability or ambition, was restored to his lands in 1541.

**BIBLIOGRAPHY.**—R. B. Merriman, *Life and Letters of Thomas Cromwell* (1902), assembles the better part of the known facts but is heavily marred by a complete lack of understanding. There is a good biography: A. G. Dickens, *Thomas Cromwell and the English Reformation* (1959). Cromwell's work in government is dealt with in G. R. Elton, *Tudor Revolution in Government* (1953). For Cromwell's political theory see also W. G. Zeeveld, *Foundations of Tudor Policy* (1948). (G. R. E.)

**CRONACA, IL** (SIMONE DEL POLLAIUOLO) (1457–1508), Italian architect, was not related to Antonio and Piero Pollaiuolo (q.v.) and according to Vasari it was his accurate accounts of the marvels of Rome that earned him the nickname of "Il Cronaca" (the chronicler). Born in Florence, he stayed in Rome (c. 1475–80) and then returned to Florence. He designed the courtyard and the monumental cornice of the Palazzo Strozzi there, the cornice being a clear result of his study of Roman architecture. His responsibility for the church of S. Francesco al Monte, Florence, is documented and it seems likely that he built the sacristy of S. Spirito in accordance with a design by Giuliano da Sangallo.

See G. Vasari, *Lives of the Most Eminent Painters*, English trans. by G. du C. de Vere (1912–15). (L. D. Ea.)

**CRONJE, PIET ARNOLDUS** (c. 1835–1911), Boer general who played a prominent part in the early stages of the South African War, was born in the Cape Colony but was taken in early life to the Transvaal, during the Great Trek. There, in Nov. 1880, he began the rebellion against British rule, leading resistance to the distraint of goods of a farmer who had refused to pay taxes. In the war that ensued, he was commandant at Potchefstroom and forced the surrender of the British garrison just as a general armistice was being arranged (March 1881). Later he entered the *volksraad* (parliament) of the South African Republic, where he supported Pres. Paul Kruger. He became

superintendent of natives and a member of the executive council. In 1896 he commanded the Boer force which captured the Jameson raiders at Doornkop (Jan. 2). When the South African War broke out in 1899, Cronje, now a general, assumed supreme command in the west and began the siege of Mafeking. After a number of engagements, he repulsed a general attack on his position at Magersfontein (Dec. 11, 1899), thereby checking for two months the northward advance of the British column. In the campaign of Feb. 1900 Cronje, still at Magersfontein, opposed Field Marshal Lord Roberts' army but failed to prevent the relief of Kimberley. Retreating eastward, he was surrounded at Paardeberg where, after inflicting very heavy losses on the British, he was forced to surrender with about 4,000 burghers (Feb. 27, 1900). Cronje was a courageous and successful leader of men, but his thinking was slow and inflexible and his strategy faulty. He was, moreover, handicapped by the weak leadership of the commandant general, Piet Joubert, and the poor discipline characteristic of the Boer commandos early in the war. He was a prisoner of war at St. Helena until the end of the war (1902). He retired subsequently to Klerksdorp, Transvaal, dying there on Feb. 4, 1911. See SOUTH AFRICAN WAR. (N. G. GA.)

**CRONUS**, an ancient deity, most likely belonging to the pre-Hellenic population of Greece and not much worshiped by the Greeks themselves. The etymology of the name is unknown but is probably not Greek; the derivation from *chronos*, "time," is impossible. Cronus' functions are connected with agriculture; in Attica his festival, the Kronia, at harvest time, resembled the Saturnalia. In art he is shown as an old man holding an implement, probably originally a sickle but interpreted as a *harpe*, or curved sword.

In mythology he is the son of Uranus (Heaven) and Gaea (Earth). Many of Uranus' children were monsters, so he hid them in the earth as soon as they were born. Gaea at first mourned, then begged her children to help her revenge herself on their father. Cronus alone consented; Gaea gave him the *harpe*, with which he castrated Uranus. In this way Cronus (like similar heroes in Maori, near eastern, Indian and Chinese myth) separated heaven from earth. He now became the lord of his brothers, the Titans and monsters, and shut up the most dangerous of these (the *Hekatoncheires* or Hundredhanded Ones) in Tartarus. He took for consort his sister Rhea; and, warned by his parents that his own child would overthrow him, swallowed Hestia, Demeter, Hera, Hades and Poseidon as soon as they were born. But when Zeus was born, Rhea hid away the infant in Crete and tricked Cronus into swallowing a stone instead. Zeus grew up, made Cronus disgorge his brothers and sisters, waged war on Cronus and was victorious. (The stone, which Cronus had also brought up, later was shown and venerated at Delphi.)

After his defeat by Zeus, different versions of his story make Cronus either a prisoner in Tartarus (or on an island near Britain, guarded by the *Hekatoncheires*) or king of the Golden Age. According to this latter legend, men lived in a state of paradisaic innocence under his rule, and the earth bore all its fruits untilled. Cronus in time was rationalized into a great and beneficent western king, hence the late and artificial Italian tale that he was welcomed to the future site of Rome by Janus, the god of beginnings (also rationalized into a king), founded a city there and taught the people navigation, coinage and other skills.

Because of his swallowing of his children, Cronus is frequently identified with foreign gods, notably with the Semitic *baalim* (e.g., Baal Saturnus on numerous Roman inscriptions at Carthage) and with Moloch, to whom human sacrifices, particularly of children, were made.

See H. J. Rose, *A Handbook of Greek Mythology* (1933).

(D. E. W. W.)

**CROOK AND WILLINGTON**, an urban district in the North-West Durham parliamentary division of Durham, Eng., lying on the western edge of the Durham coal field, Crook being 9½ mi. and Willington 7½ mi. S.W. of Durham. Pop. (1961) 25,257. Crook is the bigger of the two towns and lies in a valley in the west of the district below the uplands, which there rise to more than 1,000 ft. Willington lies in the eastern part of the

district about ½ mi. N. of the Wear river. It is a colliery town and Brancepeth colliery, the largest of the seven in the area, is immediately to its northeast. In the town is a Miners' Welfare hall. Old buildings in the district include the farm of High Woodfield, with a medieval servery; Hunwick hall, dating from the 14th century; and Witton tower, the main tower of which dates from the 16th century. Besides coal mining, the chief industries are the making of machinery for drawing tubes and wires and the manufacture of clothes and firebricks, silica bricks and fireclay.

**CROOKES, SIR WILLIAM** (1832–1919), English chemist and physicist and discoverer of the element thallium, was born in London on June 17, 1832. He studied chemistry at the Royal College of Chemistry and became an assistant under A. W. von Hofmann (q.v.). In 1854 he became assistant in the meteorological department of the Radcliffe observatory, Oxford, and in 1855 he obtained a chemical teaching post at Chester. He inherited a large fortune from his father, who had come to London as a poor tailor. From the time of his marriage in 1856 to Ellen Humphrey he lived in London, devoting himself uninterruptedly to scientific work of various kinds. He founded (1859) and conducted the *Chemical News* until 1906. He had a private laboratory at his house in Kensington Park gardens. He was knighted in 1897 and received the Order of Merit in 1910. He died in London on April 4, 1919.

In 1861 spectroscopic observations on the residue from the manufacture of sulfuric acid led Crookes to the discovery and isolation of thallium, a specimen of which was shown in public for the first time at the exhibition of 1862. In the course of investigations on the properties of thallium he observed the curious behaviour of the hot element while it was being weighed in a vacuum. This led Crookes to construct the radiometer (q.v.).

His researches on the electrical discharge through a rarefied gas led to the observation of the dark space which bears his name, and he developed his theory of "radiant matter" or matter in a "fourth state." He invented numerous devices to study the behaviour of cathode rays. On the discovery of radium he took up the study of its properties. He invented the spinthariscopes which shows the presence of traces of radium salt by the production of phosphorescence on a zinc sulfide screen.

Crookes was constantly consulted by the government on chemical questions, and one of his many practical contributions to the public welfare was his production of a glass which would effectively shield the eyes of workers from the deleterious heat rays and ultraviolet light emitted from molten glass. Crookes wrote or edited various books on chemistry, including *Select Methods of Chemical Analysis*, which went through a number of editions.

(R. E. O.; X.)

**CROOKES' TUBE**: see X RAYS: *Basic Theory*.

**CROP DRYING AND PROCESSING**. Farm crops are perishable by nature and except for those used immediately all require some attention to keep them in suitable condition until used. Treatments for this purpose can be classed as crop processing, as distinct from food processing or product processing, which are for the purpose of making a product more suitable for food or other use.

The simplest crop-processing methods are those which rely almost entirely on the climate or the property some crops have of tending to condition themselves against fast spoilage. For example, grains in many climates, if left in the field, will become dry enough to last for a long time. Some fruits and vegetables such as potatoes, with suitable exposure, will cure to a condition that protects them against rapid deterioration.

Crop processing, even when most of the treatment is left to nature, is mostly a matter of control of moisture or temperature or both. There are processing methods in which other factors are controlled, such as making silage, in which the composition of the air is important, but for the most part safe preservation of crops depends on cooling or drying. See also CROP-PROCESSING MACHINERY.

## REFRIGERATION

Fresh fruits and vegetables are particularly responsive to cool-

ing. These products continue to live after harvest and in the process of living gradually consume themselves to the point where they become useless. The rate of self-consumption depends largely on the temperature. Refrigeration is therefore one of the important crop-preserving processes. In addition to slowing the life processes of the product itself, cooling tends to prevent the activity of microorganisms. In most cases it is desirable to reduce the temperature to just above the product's freezing point. However, some products will not tolerate cooling below certain levels. For example, bananas are damaged by temperatures below about 50° F. Most fresh fruits are damaged by temperatures below their freezing points, which are usually between 28° and 32° F.

Cooling is accomplished by ventilating with cool night air, by evaporative cooling, by cold water or by mechanical refrigeration. Mechanical refrigeration provides the most positive control of the process. Precooling, or cooling prior to storage or transit, is usually done in conjunction with storage or transit refrigeration. For some products it is common practice to precool them in refrigerator cars before shipment. For further discussion of refrigeration see *FOOD PRESERVATION; REFRIGERATION: Applications of Refrigeration*.

### DRYING

For many crops, drying is even more necessary than cooling. Forages and grains are in this category. Methods for aiding natural drying are as old as agriculture. Hay may be left in the field after cutting, spread on the ground for exposure to the sun and wind. In some climates this can be done with very little hazard. In northern Europe hay is often stacked over poles standing in the fields to allow exposure to the wind and protection against rain. In South and Central America coffee beans, which are harvested in a moist condition, are spread in thin layers on huge trays that can be exposed to the sun in the daytime and slid into sheds at night. In North America corn is harvested with the kernels still on the ears and stored in cribs. These are relatively narrow buildings having slatted sides, with the slats close enough together to hold the ears, but open enough to permit the wind to blow through the stored corn. (W. V. HL.)

**Artificial Drying.**—Special handling of crops or use of machines to dry the crops sufficiently to prevent spoilage in climates where natural drying is precarious has a long history. The earliest account of artificial crop drying is probably Jethro Tull's description of an Oxfordshire farmer's success in drying grain in a malt kiln about 1700 (*Horse-Hoeing Husbandry*, 1733). In 1866 George Dyson patented a stack drier consisting of a hollow vertical cylinder through which air was blown or from which it was removed by a fan. Both James Paxman and W. A. Gibbs exhibited driers at the Royal Agricultural society's show in 1869, and Gibbs also invented a haymaking machine that agitated the unstacked hay while hot air was driven through it.

In 1919 Charles Tinker of Kilmartin patented a stack drier consisting of a cone-shaped coil of steam-heated pipes around which the crop was stacked, the drying being done in a Dutch barn. The Institute of Agricultural Engineering at Oxford experimented with stack drying from 1923 to 1925. By 1938 there were 96 centres for drying in Great Britain.

In the United States experimentation with artificial drying did not begin until 1910. The design of the first drier for forage crops was inspired by lumber kilns. By 1915 several commercial companies had produced driers, but interest lagged until 1925, when emphasis began to be placed on hay and forage crops as substitutes for cotton in the southern states. Independently, Arthur J. Mason, an engineer interested in preserving alfalfa, built an experimental plant at West Point, Miss., in 1911, patented a conveyor drier in 1916 and by 1926 made installations at Plainsboro, N.J.

The artificial drying of grass and alfalfa was also tried in the Netherlands and Switzerland. Germany and Scandinavia experimented chiefly with factory-size plants capable of drying both root and forage crops. However, before World War II the process had not advanced far in commercial farming on the continent.

(R. O. W.)

**Hay Driers.**—High moisture in stored hay not only causes

rapid deterioration of the value of the hay as feed, but frequently results in spontaneous combustion. The hazard of loss of the hay crop as well as of buildings and other property from spontaneous combustion has made many farmers conscious of the necessity of storing only dry hay. Since about 1930 the practice of barn curing hay or drying in the mow with mechanical ventilation has become common in some areas. When hay is first cut it usually has 70% or more of moisture. It wilts very quickly and dries to a moisture content of about 40%. At this stage it can be put in the mow and dried to a satisfactory condition, about 20% moisture, by blowing air through it. It may be put in the mow as loose hay just as it comes from the field; chopped and blown into the mow; or first baled in loosely bound bales. In any of these forms air can be blown through it for drying. Before the hay is put in, the mow is prepared by placing an air-duct system on the floor. There are many different arrangements of duct systems but perhaps the most common is one in which a central main duct is laid full length on the floor along the centre of the mow and smaller ducts are connected along each side and perpendicular to it. These ducts have frequent or continuous openings along their length so that when hay is put on them air forced into the duct moves upward through the hay and dries it. The fan at one end of the main duct to supply the air is usually driven by an electric motor, although a tractor or other motor can be used.

Hay drying is usually done with unheated air but sometimes the air is heated to increase the speed of drying. In this case the air is passed through an oil or gas furnace before being forced into the duct system. The air is seldom heated to more than 10° or 15° F. above atmospheric temperature, which is sufficient to assure that drying will be continuous even during the most humid weather. Higher temperatures tend to overdry the hay nearest to the ducts. The hazard of fire must be considered and is one reason that heated air is not used more widely for hay drying.

**Grain Driers.**—Even in the 19th century heated-air grain driers were used to some extent in terminal elevators and mills. About 1930, when the development of hybrid seed corn changed the production of corn seed to a specialty, the relatively high value of the seed made it economical to dry it mechanically. Shortly after World War II mechanical drying of grains on the farm came into general use. As with hay driers, grain driers may use either heated or unheated air. When heated air is used the drying is usually done in special drying compartments through which the grain flows or in which it is held for the relatively short time required for drying. One exception is ear corn, which is sometimes dried in cribs with heated air. Drying with unheated air is usually done in storage bins and the grain may remain in the same compartment for storage after drying is completed.

The advantages of heated air in grain drying are: (1) drying of each batch is completed in a few hours so the drying operation can be part of a continuous-flow harvesting-drying-storing or sale process; (2) the progress of drying is independent of the atmospheric temperature or humidity; (3) with limited power available more grain can be dried in a harvesting season. The advantages of unheated air are: (1) less first cost for the drying equipment; (2) less supervision of the operation is required; (3) there is no expense for fuel and no fire hazard.

The capacity of a heated-air drying system depends greatly on the initial moisture content of the grain. With such grains as wheat and oats it is seldom necessary or economical to have an initial moisture content of more than about 20%. With corn it is frequently desirable to harvest the crop with as much as 30% moisture. Initial moisture for rice is frequently between 20% and 25%. The rapidity with which moisture can be extracted from grain depends on the drying temperature. For this reason the capacity of a given drying compartment can be increased substantially by raising the drying temperature. Temperatures up to about 200° F. are used for feed grains. With some grains, however, it is necessary to hold the temperature down even though this decreases the drying capacity and therefore increases the per bushel cost. Seed grains are reduced in germinating power if temperatures over about 110° F. are used. Rice is subject to

damage during milling if it has been dried at temperatures above about 130° F. Such damage is less if the rice is dried in several passes, that is, if only a part of the excess moisture is removed during one pass through the drier. The rice is then allowed to temper in a bin for several hours after which it is again put through the drier. Sometimes several such passes are made. The wet-milling processors find that corn dried at temperatures over about 130° F. cannot be processed satisfactorily. The effect of drying temperature on livestock feed is not well understood. There is evidence that the feeding value is somewhat lowered by temperatures over about 150° F.

Fuel oil and gas are usually used to heat the air. For most purposes the products of combustion of these fuels do not harm the grain, so many driers are used in which the burned gases are included with the air that passes through the grain. Appropriate safety devices are essential parts of heated-air driers. These include a device for limiting the temperature of the drying air, provision for stopping the burner if the fan fails and provision for stopping the fuel supply and fan if the flame fails.

Grain drying with unheated air is usually done in storage bins. Several weeks may be needed to complete drying. This method is most practical in relatively dry climates but it can be used successfully in humid areas where, however, the rate of air supply must be greater. If too little air volume is used the grain in the upper layers in the bin will mold before drying is completed. Economical application of unheated-air grain drying is achieved by designing the system so that the rate of air supply is appropriate to the quantity of grain, its initial moisture content and the climate. If too much air volume is used the operation is uneconomical in use of power. If too little air is used drying does not prevent spoilage of at least part of the grain.

#### AERATION

Another process, not to be confused with grain drying, is that of aeration for the prevention of damage to stored grain that is already dry. In the absence of aeration there is a tendency for moisture in stored grain to move from one part of the bulk to another. This results from temperature differences in different parts of the bin. The moisture content of some of the grain in the bin may rise to a serious level if the temperature differences are not eliminated. This is done by ventilating the grain with a low volume of air, much lower than is required for grain drying. Since about 1950 the practice of aerating grain stored for more than a few weeks has become almost universal in large storages and it is used to some extent in small farm-type bins.

**CROP INSURANCE:** see CASUALTY INSURANCE.

**CROP-PROCESSING MACHINERY.** The machinery described under this heading is for preparing crops for market, storage, food and feed, and for handling feed for livestock. The machines for the most part are belt driven by an internal-combustion engine, tractor or electric motor, and occasionally by a steam engine. Crop-drying and processing methods are discussed in the article CROP DRYING AND PROCESSING. For information on corn pickers, cotton pickers, etc., and for further discussion of combines and other harvesting machinery see HARVESTING MACHINERY.

See also FARM BUILDINGS; FARM MACHINERY; RURAL ELECTRIFICATION.

**Threshers.**—When small grain is harvested with a header, binder or reaper it must be threshed before it is ready for market. This is the purpose of the thresher which performs three main

functions—threshing or faling the grain out of the heads, separating the grain from the straw and cleaning the grain. Threshing is accomplished by the cylinder (tooth, rasp, sometimes called fluted or rub bar, or flail type) and concaves, which knock the grain out of the heads, part of it falling through the grates underneath the rear portion of the cylinder. The remainder passes with the straw which is directed onto the oscillating or vibrating straw racks or strawwalker by a beater, where separation takes place. A grain pan underneath catches the grain from the cylinder and straw rack and passes it on to the chaffer, sieves and screens. This, aided by a fan, is the cleaning mechanism which removes the weed seeds, dirt and chaff.

The grain then gravitates to the grain auger, thence successively to a vertical conveyer, weigher and bagging or wagon spout. Another auger directs any unthreshed heads or tailings to an elevator which delivers them back into the cylinder. A wind stacker mounted at the rear of the machine blows the chaff and straw through a pipe onto a stack. Self-feeders and conveyers are used for carrying the bundles or sheaves to the cylinder. Volume governors for effecting uniform feeding, bandcutters for cutting the bands and various other features are available according to the make of machine. For threshing soybeans, peas, beans and similar crops low cylinder speeds (400 to 600 r.p.m. in place of the normal 1,000 to 1,200 r.p.m.) are required to avoid excessive cracking of the seed. The size of the thresher is determined by the width of the cylinder and the width of the machine at the rear. The smallest thresher is about 20 × 28 in. (20-in. cylinder and 28-in. width of machine) and the largest machines are about 40 × 62 in. The foregoing applies to the machines used mainly in the United States and Canada.

In England and continental Europe more care is taken of the straw, both in threshing and afterward. Often the bands are cut by hand and the bundles are hand-fed into the cylinder. The fluted-bar cylinder which does not break the straw as badly as the spike cylinder is more commonly used. What light material there is, however, such as chaff and short straws (cavings), is discharged from the thresher and not allowed to get into the straw. This leaves clean straw which is usually delivered directly into a press or trusser which bundles and ties it and passes the bundles up a chute into the mow or for loading onto a wagon. However, balers patterned after the United States type of construction are used to some extent in place of the presses. The standard-size thresher in England is 54 in., which is the width of the cylinder and also the approximate width of the machine. Although in the main the work accomplished by U.S. and British machines is more or less the same, a few features occur in the British that do not appear in the American, such as the awner and chobber to remove the bristles or beards and any broken spikes, the second cleaning fan, the rotating screen and the extra grain spouts. The awner and chobber, which are enclosed in a housing with an adjustable opening at one end, consist of a shaft upon which are mounted in succession two or three turns of an auger, a series of spirally arranged knives (the awner) and two disks of different diameters fitted with several bar elements with projecting teeth giving the appearance of a cone. When threshing barley, the grain is conveyed to the awner by an elevator and an auger for removing the bristles or beards and then is passed to the chobber for further rubbing.

**Silo Fillers (Ensilage Cutters).**—Silage or ensilage (*q.v.*) is herbage stored in a green, moist state. Silage possesses certain advantages as a feedstuff, and the practice of growing succulent fodder crops such as corn (maize), alfalfa, oats, grass, etc., for making it, particularly in humid regions, is common. Silage may be stored in trenches or pits, picket silos or tower silos.

For making silage the crop is mowed green and usually cut up into short lengths by a portable combined silage cutter and blower. The material to be cut is deposited on a conveyer which carries it to a pair of feeding rolls, the lower one fixed, the upper one floating, thence to the knives of flywheel or lawn-mower type. From the knife housing, the chopped material is generally blown into the silo through a vertical sheet-metal pipe leading into the top of the silo, often 50 to 60 ft. high and frequently higher.

Sometimes, however, an endless belt or chain conveyer is used for grass silage. Some machines are provided with a molasses pump and distributing system for adding molasses or other preservative to crops deficient in sugar.

**Hay and Straw Cutters (Chaffcutters).**—The chaffing or chopping of hay and straw into short lengths is done to facilitate drying or mixing with other feeds and to assist in the feeding of livestock. In a chaffcutter the hay or straw is fed into a long chopper or a trough, at the bottom of which is a moving belt for conveying the uncut fodder to toothed rollers. These rollers hold the stalks while the knives descend and cut the fodder. The knives, which may be curved or straight, are usually attached to the spokes of the flywheel and so set that they cut the fodder as it is pushed forward by the feeding rollers against the mouth or shear plate of the machine. The length of cut is varied by adjusting the speed of the conveyer.

**Baler or Baling Press.**—Where hay or straw is baled from the stack a portable baler is used. As a charge of hay is placed on the platform and pushed into the hopper it is forced into the baling chamber by a feeder head. The plunger then moves forward and compresses this charge and returns momentarily to its initial position while another charge is being placed in readiness. Grooved blocks inserted at intervals by the operator determine the length of the bale. Baling wires or ties are pushed through the grooves to secure the bale and then tied. As the bales are forced from the press the blocks drop to the ground ready for use again. The tightness of the bale may be controlled by hand screws at the discharge end of the baling chamber. Power may be supplied through sweeps drawn by work animals or by an internal-combustion engine.

In the United States the more common sizes of the baling chamber are 14 × 18 in., 16 × 18 in. and 17 × 22 in. The baler is pulled through the field and picks up the hay or straw from the windrow or swath by means of a revolving cylinder with wire fingers on the outside. The operation of the baler is automatic. An apron feeds the hay into the compressor chamber where a knife on the side of the plunger cuts each bunch of hay loose so the bundles will be cleanly separated. The bales are tied with either twine or wire by means of two needles and a knoter head. This is the same tying process as performed by the grain-binder knoter head.

**Husker-Shredder.**—In regions of the United States where corn is harvested for the stover (stalks) as well as the grain, frequent use is made of the husker-shredder (fig. 1). As in the case

FIG. 1.—HUSKER-SHREDDER

of the mechanical corn picker the cornstalks with ears attached go through the snapping and husking rolls (these may be combination rolls, the lower or forward end snapping and the upper end husking) where the ears are snapped off and husked. The ears are then delivered by an elevator into a wagon or the crib and any shelled corn passes through a cleaning unit similar to a thresher and thence to a discharge spout for sacking or other disposal. The husks and stalks pass through the shredder head where they are shredded and then disposed of through a blower. This material is used for feed or bedding.

**Mills (for Crushing, Grinding, Kibbling).**—These machines, often known as feed grinders or feed mills, are used principally for milling cereals, corn, soybeans, etc., before feeding to

DRAWN ESPECIALLY FOR "ENCYCLOPEDIA BRITANNICA" BY RAY I. SHAWL

FIG. 2.—AN AUTOMATIC ELECTRIC MILL FOR MIXING, GRINDING AND DISTRIBUTING GROUND FEED TO THE FEED TROUGH. THE MILL MEASURES EACH FEED TO BE GROUND PROPORTIONATELY

livestock, so as to aid digestion, as, for example, in the case of crushed oats, or to facilitate mixing with other fodder; e.g., ground ear corn or chaffed hay or straw. The degree of grinding is very coarse compared with flour, though some mills used by farmers can grind wheat sufficiently fine for making whole-meal bread.

**Crushers or kibblers.** are used mainly for oats, corn and linseed, which are bruised, broken or flattened without being ground into a meal. The essential components are two roughened or fluted rollers which crush the material as it passes between them. One roller is fixed and the other adjustable so that different grains can be crushed or the fineness of crushing varied. A crusher may be hand or power driven.

**Grist or grinding mills** are invariably power driven and utilize small disks (smooth, rough or fluted) revolving at a high speed in a vertical plane for grinding grain fed from a hopper. Stone was originally used for the grinding disks, but chilled metal and artificial stones are now commonly employed. The disks may be flat or conical and provision is made for adjusting them to vary the fineness of grinding. Where a farmer desires to grind whole-meal flour the mill may be provided with a meal sifter. Combined crushing and grinding mills are also made; the essential components resemble those described above.

**Hammer Mills.**—The hammer mill to a considerable extent replaced the burr or gristmill for grinding small grains including wheat, oats, barley and shelled corn, as well as ear corn and dry roughages. The grain is fed by gravity from a hopper or by a conveyor into rapidly revolving hammers which pulverize the material and force it through grinding liners or screens encircling the revolving hammers. The size of the holes in the screen determines the degree of fineness of the meal. As the material passes through the screen a blower carries it into a cyclone (separator) where the dust settles. From there it gravitates into sacks or is conveyed to a bin. For grinding roughage, such as cornstalks, auxiliary knives are provided to chop it into short lengths before it falls on the hammers.

In the second half of the 20th century, combine harvesters that would reap, thresh and grind grain for feed in one operation were introduced, tending to make hammer mills, gristmills and crushers obsolete.

**Automatic Livestock and Poultry Feeders.**—The scarcity and high cost of farm labour in the United States has caused both grain and livestock farmers to increase the size of their farms in order to make the most economical use of the larger labour-saving machines. This change was well under way in the second half of the 20th century. At the same time the availability of electricity on many farms made it possible for livestock and poultry farmers

FIG. 3.—DRYING GRAIN IN AN ENCLOSED STORAGE BIN WITH A PERFORATED METAL BOTTOM. HEATED AIR BLOWN UNDER THE FLOOR RISES THROUGH THE GRAIN, DRYING IT SLOWLY

to install the new automatic feed-grinding, mixing and distribution systems for feeding. Fig. 2 shows an installation of this type. The grains and supplements are placed in overhead or ground-level storage bins from which they are delivered to the grinding mill by gravity or by small-diameter augers. The drawing shows an arrangement for four different ingredients being fed into the mill to be ground, mixed and delivered to the feeding storage or trough. It is possible to deliver the feed directly to the feeding troughs by an auger as shown or the feed can be delivered several hundred feet through a small auger also operated by an electric motor. In the drawing a second auger above the feed trough delivers the feed down the trough, allowing it to fall through holes until the trough is full. The grinding equipment can be set to operate by a time clock for a definite length of time or it can be equipped with a switch at the far end of the auger which will automatically shut off the mechanism when the trough is full. It is also possible to blow the feed through plastic pipe mounted overhead or buried in the ground. The plastic pipe can be bent around corners which makes it easy to install.

The proportion of the various ingredients fed to the mill is controlled by a small ratchet-driven auger in each compartment at the top of the mill. The quantity of each ingredient is controlled by a separate dial and the rate at which the material is fed to the mill is controlled by a master dial. Other methods of controlling the quantity of each ingredient are the electric-vibrator type and the belt- or chain-driven volumetric type. Equipment is also available for delivering ear corn from a crib to the grinder. A mill of the type described, when driven by a three-horsepower

electric motor, can grind 1,000 to 2,000 lb. of feed an hour. Ensilage can also be automatically delivered from the silo to the feed troughs.

**Corn Shellers.**—For shelling corn in the ear, use is made of the corn sheller—the cylinder type for large capacity and the spring type for small capacity. In the cylinder type the ears are fed into the sheller by a conveyer and feeding spiral where the conical-shaped lugged cylinder revolving within the shelling cage causes the kernels to be rubbed off the cob. The shelled corn falls onto a cleaning screen, exposed to an air blast, and then is discharged into bags or a wagon.

The spring-type sheller may be of the one-, two-, four- or six-hole size. The one- or two-hole type may be operated by a hand crank or a small electric motor, but the larger ones require more power. The shelling is effected by a shelling wheel fitted with projections. The corn is fed into the hole or holes as the wheel revolves and, with the aid of a rag iron or weight under spring pressure for holding the ears against the wheel, the kernels are rubbed off.

**Cake Breakers.**—These machines, for hand and power operation, consist of a feeding slot and one or two pairs of toothed or spiked metal rollers which break linseed cake, soybean cake or similar feed material as it passes between them. The distance between the rollers can be varied to alter the size of the broken pieces, called nuts; these are passed over a riddle or coarse sieve in order to separate the meal and fine particles from the nuts.

**Root Cleaners, Cutters and Pulpers.**—These machines are used mainly to chop up swede turnips or rutabagas which are hard. Mangels and white or soft turnips are usually fed whole, though they may occasionally be sliced. Cleaners consist of a number of iron bars joined together in the form of an open cylinder which

FIG. 5.—REVOLVING-DRUM TYPE OF FORAGE DRIER, TRIPLE-DRUM DESIGN

can rotate in an inclined plane. The roots are fed into a hopper at one end and pass by gravitation as it rotates along the cleaner into the cutter or pulper, any loose soil falling through the iron bars in the process. The rate of cleaning is regulated by altering the inclination of the cylinder to the horizontal. Cutters or pulpurs are of various types and may be operated by hand or power. The commonest types work on the rotary principle and have a hollow barrel or drum carrying cutting devices of various shapes on the periphery. The roots are fed from a hopper, and the barrel, which is mounted on a frame, can rotate in either direction so that the roots can be sliced by one set of knives and cut into fingers by the other. It is usual to slice roots for cattle and cut them into fingers for sheep.

**Drying Agricultural Products.**—Grain with high moisture content at harvest time should be dried to the proper moisture per cent for sale or storage. It is practical to dry grain with a 30% moisture content but the grain should be allowed to field dry as much as possible. Grain should be dried down to 11% or 12% for storage in tight bins or to 15½% for immediate sale. In the United States the blower supplying hot or cold air for drying is usually of the type shown in fig. 3. The drier fan is driven by a 3- to 7½-h.p. electric motor or by a tractor

FIG. 4.—COMPLETE BATCH DRYING SYSTEM (RIGHT) FROM HOT-AIR BLOWER TO STORAGE BINS. THE CROSS-SECTION DRAWING (LEFT) SHOWS THE HOLDING BIN ABOVE TWO DRYING COLUMNS. HEATED AIR BLOWN INTO THE CENTRE SPACE PASSES THROUGH THE LAYERS OF GRAIN

FIG. 6.—TRAY DRIER

power take-off shaft. The large horsepower of the tractor engine allows the fan to be stepped up to a higher speed, thus delivering much more air. The electric-motor-driven driers deliver from 15,000 to 30,000 cu.ft. of air per minute depending upon the size of the unit. Drying temperatures usually range from 140° to 180° F. These driers may burn from 3 to 25 gal. of fuel oil an hour depending on the drying temperature and the drier size. Fig. 3 shows a low-cost type of drier consisting of an airtight storage bin with a perforated floor. The hot air is blown under the floor and passes up through the layer of grain. The blower can be started as soon as a foot or more of grain covers the floor. Grain to a thickness of six feet can be dried in about 70 hours depending upon the moisture content at the start and the per cent desired at the finish. A considerable amount of corn is shelled as it is harvested in the field and the moisture content is usually high enough to require drying before storing in tight bins.

The most popular type of grain drier is the batch drier shown in fig. 4. The drying bin holds from 200 to 300 bu. depending on the size of the drier. There is a storage bin for damp grain above the drying area. The cross section of the drying bin at the left shows a double column of grain about 16 in. thick. Hot air is blown into the centre and passes out through the layers of grain. When the batch is dry it is augered out at the bottom and delivered to the permanent storage bins. The blower is the same as that described before.

Another type of machine can be set for a certain number of hours of drying after which it empties out the dried grain and refills itself from the storage bin above. Still another type is known as the continuous drier. In this machine a thinner layer of grain flows through the drying area at a slow enough rate to be dry by the time it passes out the bottom.

From three to seven hours will be required to dry the grain in the batch type, depending on the amount and its moisture content. From 3 to 25 gal. of fuel oil per hour will be burned to dry a batch of grain.

**The Rotating-Drum Type.**—A stationary type of drier for alfalfa and grasses consists of a large rotating drum (fig. 5) into which the shredded or cut material to be dried is fed. The material is subjected to rather high temperatures for quick drying as it passes through the machine. The dried material is cooled and fed into a hammer mill where it is ground into a meal and packaged in cloth or paper bags for shipment. The tray drier (fig. 6) may be of various designs, one of which is quite popular in England for drying hay. Coke is used for fuel and the hot gases from the furnace are blown under two sections containing mats of hay. The section with green hay is arranged so the hot gases pass up through the mat and into the open until the hay is half dry, when it is pitched by hand into a second compartment with a cover. Here the gas passes through the half-dry hay and back to the furnace to be reheated. There are two additional compartments symmetrically with the first two which are being prepared while drying is taking place in the others. In the duct-type or mow drier (fig. 7) a series of ducts open on the underside and raised an inch off the floor cause the air to pass through the surrounding hay under pressure produced by a blower. These ducts are about six feet apart and green hay may be piled on them to a depth of about five feet until dry, when an additional five feet may be added and so on up to the height of the mow. Depending upon atmospheric conditions a five-foot depth is usually dried in from 10 to 25 days if no heat is used.

COURTESY OF VIRGINIA POLYTECHNIC INSTITUTE

FIG. 7.—MOW DRIER FOR LONG OR CHOPPED HAY. COLD AIR IS USED, AND THE SIZE AND PLACEMENT OF THE DUCTS IS SUCH THAT AIR IS DISTRIBUTED EQUALLY OVER THE ENTIRE DRYING AREA. A FIVE-FOOT LAYER OF HAY TAKES 10 TO 25 DAYS TO DRY, DEPENDING UPON MOISTURE CONDITIONS

**Elevators.**—Where large quantities of hay or straw are to be stacked or placed in the mow, or grain in bins or cribs for storage, much labour is saved by the use of elevators. A common type consists of a hopper, a long trough, usually rectangular in section and open on top, and an endless belt or chain fitted with forks for conveying hay, flights (cross-pieces) for conveying ear corn and sometimes small grain and flights of special design for working inside a spout for small grain, shelled corn, etc. The whole is mounted on a frame carried on wheels for convenience in transport and the machine is made in sections so that it can be folded.

The material is fed into the hopper from which it is picked up by the forks or flights and conveyed up the trough to the top of the stack, grain bin, mow or silo. A second type of elevator consists of a metal pipe with an auger turning inside and driven by a small electric motor or gasoline engine. This elevator comes in various lengths and can be easily handled by one or two men. The end of the auger pipe is inserted into the grain and the turning auger moves the grain at a rapid rate. A third type of elevator is the blower. Grain is dropped into a hopper from which it is fed into an air blast and carried through a pipe to the storage bin. This type of elevator is quite heavy but can be moved from place to place.

Elevators may be operated by animal power, internal-combustion engine, electric motor or, when used for stacking straw, direct from the threshing machine.

**CROPS.** Crops are plants and their products usually grown with special care or for a special purpose, and in most instances harvested to yield a product for which there is a market demand. Emphasis is placed on the ability to produce a harvest. The Germans use the word *Ernten* synonymously for crops and harvests. The harvesting or gathering of the product may involve the entire above-ground portion of the plant, as in the case of green vegetables or of forage crops cut for either hay or silage. It may be limited to the harvesting of underground tubers, as in the case of potatoes. In the cereals the entire plant may be cut or harvested but generally only the seeds are marketed. The stems and leaves, that is, the straw, of the cereals are of value for returning organic matter to the soil, for bedding and, more recently, together with cornstalks, for the manufacturing of paper. In parts of the world, notably in Asia, the straw of the cereals and stalks of other plants are valued sources of fuel.

Not all crops are harvested in the accepted manner. Pasture crops are grazed by animals and are thus converted into milk, beef, mutton or pork, and the term crop is used by livestock producers who refer to their pig, lamb or calf crops; nevertheless its use is generally reserved for the designation of plant products.

The production of a marketable product may yield its place to crop production for special purposes, as where cover crops are grown to protect land from wind or water erosion and from nutrient losses by leaching. Bare unprotected soil is subject to physical and chemical losses in that particles may be removed by the force of wind or water or soluble elements may be lost by being washed out. Plants used for cover crops may also serve as green manure crops by being plowed under for soil improvement (see *CATCH CROP*).

Crops may be used for food, for feed or for the production of special products. Fruits and leafy vegetables are used for direct human consumption. Wheat kernels are processed to produce flour. The by-products of the milling industry, the germs and

bran separations, are used largely in animal feeds. Sugar is extracted from either the stems of sugar cane or the roots of sugar beets. Fatty oils, used either for food or in industry, are extracted from the seeds of such crop plants as corn, soybeans, cotton, peanuts and flax, or from the fruits of the olive, the dried meat of the coconut or from the kernels or the fibrous pulp of the oil palm. Essential oils used in the flavouring of foods are distilled from such plants as spearmint and peppermint. In addition there are the drug crops, such as belladonna, aconite and castor beans, to name only a few, and the stimulants such as tobacco, coffee and tea.

The designation of plants as food and feed crops varies in different parts of the world. It is associated with the economic status of various countries. Around 90% of the corn produced in the United States is fed to livestock, only about 8% being processed for human consumption. Most of the corn crop grown in southern Europe, Mexico, Asia and Africa is used for direct human consumption. In the United States barley is produced for feed and malting; it is used as a food crop in northern Africa and in Asia. Population pressure in southeastern Asia forces the soybean into the food-crop class, in that it provides a cheap source of protein, fat and oil. In the United States the crop is grown primarily for oil, for industrial uses and as a forage crop.

Many crops are of importance not only for their primary use but also for their by-products. Oil-producing crops yield not only oil but also high-protein feeds. Cotton is a fibre crop, yet an average ton of cottonseed (q.v.) produces 311 lb. of crude oil, 906 lb. of meal, 520 lb. of hulls and 143 lb. of linters or short fibres that remain on the seed after ginning. It is difficult to justify the continuance of the sugar-beet industry on the basis of the sugar produced without consideration of the value of the by-products of this industry, namely, molasses, beet pulp and the tops and leaves of the beet plant.

The area of production, or the distribution of crop plants, is determined by a multitude of factors. Not only must the climatic and soil conditions be favourable but there must also be an economic justification for the crop. Technological, social, historical and even political forces enter into the original establishment and continued cultivation of a crop in a given area.

The origin, development and continuance of the sugar-beet industry in Europe and in the United States provides a good example of the operation of these factors. It took the technological know-how of Franz Carl Archard to apply the discovery made by his teacher, A. S. Margraff, in 1747 that sugar crystal could be separated from the white beet. Archard built the first practical sugar-beet factory in Lower Silesia in 1802. In this venture he received the material assistance first of Frederick the Great and subsequently of Frederick William III of Prussia. Napoleon I encouraged and subsidized early beet production in France in 1811, with the double objective of producing sugar on the continent of Europe and countering the British blockade. These actions set the pattern of providing governmental assistance to the young industry in the European countries and later in the United States where the sugar-beet acreage is set by the federal sugar program. Plant breeders made their contributions to sugar-beet production by the development of beets with a high sugar content and the breeding of varieties with disease resistance.

To this must be added the development of single-germ seed, containing only one seed per seed ball. The availability of this seed makes possible precision planting, which facilitates field thinning. Other technological advances were the development of equipment making possible the mechanization of production and harvesting of the crop, and improvement of sugar through new extraction methods in factories.

Temperature relationships determine the limits within which crops may expand into the higher latitudes. Cotton ceases to be a crop of economic importance in areas with growing seasons of less than 185 days. Barley, on the other hand, being able to complete its growth cycle in a much shorter period, is adapted to areas with short and cool growing seasons. This accounts for the occurrence of this crop in high latitudes and at high elevations.

The availability and seasonal distribution of moisture establish other limits to crop expansion. Timothy and Kentucky bluegrass

occur in humid regions while crested and Siberian wheat grass survive and produce forage in extremely dry areas. Corn yields its place to the sorghums in the southern Great Plains area because of its more exacting moisture and temperature requirements; the sorghums will produce a crop under greater moisture stress than will corn.

Climatic and soil conditions determine not only the distribution of crops but also their characteristics in relation to special uses. Wheat produced in humid woodland climates, as in the eastern part of the United States and in western Europe, is soft and low in protein. It is suitable for the cookie and pastry trade. The winter and spring wheats produced in the areas of the drier grassland climates of the Great Plains and the Crimean section of the U.S.S.R. are hard, vitreous and high in protein, and for that reason are in demand by the bread trade. These variations in kernel characteristics are accounted for mainly by climatic differences in the two areas. The nature of the soil and the choice of varieties also contribute to the differences indicated. See AGRICULTURE and articles on specific crops.

(K. H. K.)

**CROQUET AND ROQUE**, an outdoor game which may be played on the lawn or on a smooth hard-surface court with mallets with which the players manipulate balls through a series of wire wickets, hoops or arches.

The game evolved, according to some writers, from the *paille-maille* which was played in Languedoc at least as early as the 13th century. It was a popular game of the royal families of France in the 17th century before it crossed the channel to England and became the game of the kings and queens. By 1850 it had become one of the most popular outdoor sports in England and by 1870 it was being played in almost every section of the United States, but not as an organized sport.

In Great Britain the first all-comers' meeting was held at Moreton-in-the-Marsh, Gloucestershire, in 1867. In 1870 the All England Croquet club was formed, the annual contest for the championship taking place on the grounds of that club at Wimbledon. After being for ten years or so the most popular game for the country house and garden party, croquet was practically ousted by lawn tennis, until, with improved implements and a more scientific form of play, it was revived about 1894-95. In 1896-97 was formed the United All England Croquet association, now known as the Croquet association. The chief events of the year are played on the club croquet lawns at Hurlingham and Roehampton, and the tournaments at Parkstone, Eastbourne, Brighton, Cheltenham and Budleigh Salterton are specially popular.

Croquet flourishes in many parts of the Commonwealth of Nations, with affiliated associations in Australia, Tasmania, New Zealand, etc. Some of these associations have as many as 300 clubs affiliated to them. A team from Australia visited England in 1925 and the test matches were won by the home country. Further test matches were played in 1928 and 1935 (won by Australia) and in 1937 (won by England). In 1950 the international trophy was played for in New Zealand and won by the New Zealand team, but England recovered the trophy when a New Zealand team visited England in 1956.

The game is also popular in the U.S. where a National Croquet association was organized in 1882, and regulations and rules were established for an organized sport. In 1889, at a tournament meeting in New York city, Samuel Crosby suggested that the letters "c" and "t" be dropped from the word croquet making it roque. The organization later became known as the National Roque association (see *Roque*, below). Lawn croquet continued to be played throughout the country, but organized croquet was lost sight of for a number of years. Then in 1950 at Oklahoma City, Okla., a National Croquet association was organized to promote croquet as an organized sport in the United States.

There are several versions of croquet and the rules and court dimensions differ in Great Britain and the United States. Croquet terms, shots, strokes, styles of play and methods of scoring are identified in *British Croquet*, below.

**British Croquet.**—In Great Britain the official game of croquet

is association croquet. It is played between two sides, playing alternate turns, each side consisting of either one or two players. Four balls are used, one side playing blue and black and the other side red and yellow. Each side has 26 points to score, 13 with each ball.

A game is won by the number of points which the loser has still to make when his opponent has hit the peg with both balls. Any ordinary turn may be played with either ball of the side, provided that no ordinary turn may be played with the same ball again until all the balls are in play. However, when a side consists of two players, one partner plays throughout with one ball of the side and the other partner with the other.

The court is rectangular, 35 yd. long by 28 yd. wide, within a boundary defined by a continuous line (see fig. 1). Corners I, II, III and IV are marked by coloured flags. Portions of the yard line, 13 yd. long measured from the corner spots at corners I and III toward corners IV and II, respectively, are called balk lines. Eight white pegs, not exceeding  $\frac{1}{4}$  in. in diameter or 3 in. in height above the ground, are placed on the boundary, at distances of 3 ft from the corners of the boundary. The square yard formed at each corner by the two corner pegs, the corner spot and the corner flag is called a corner square. The six arches, or hoops, are of round iron,  $\frac{5}{8}$  in. in diameter and of uniform thickness. They stand 12 in. in height above the ground, vertical and firmly fixed. The crowns of the hoops are straight and at right angles to the uprights which should be  $3\frac{1}{2}$  in. apart, inside measurement ( $3\frac{1}{8}$  in. for certain competitions between experts), from the ground upward. The winning (centre) peg is of wood and of uniform diameter above the ground of  $1\frac{1}{2}$  in. The setting of the hoops and peg is as shown in fig. 1, the order of making the points being indicated by the arrows. Each hoop is run twice and the peg is hit once, and may be so from any direction. (The game is still occasionally played with two pegs, one near each end of the court on the centre line, each being struck when six hoops have been run and this is the official game in the U.S., as described in *Lawn Croquet*, Pro-

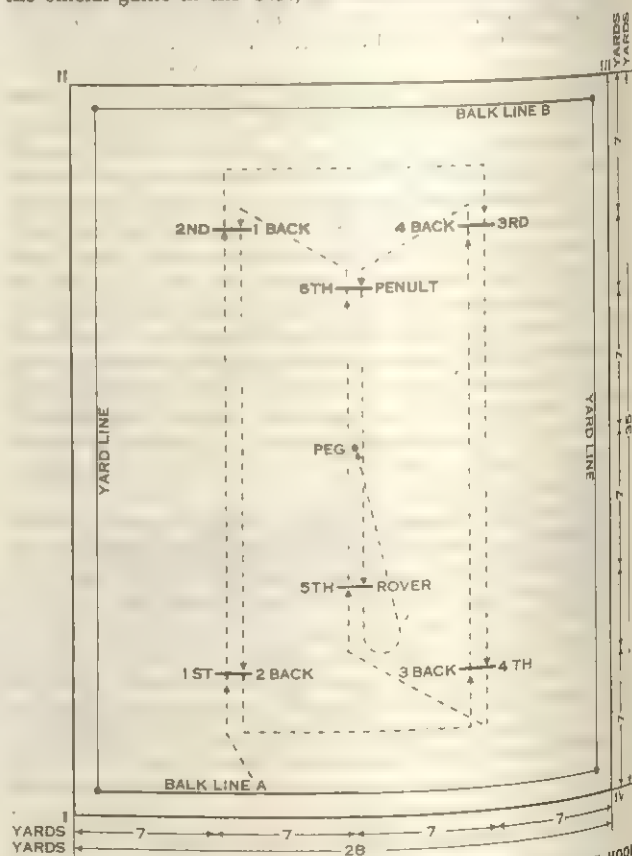

FIG. 1.—PLAN OF BRITISH CROQUET COURT SHOWING SETTING OF HOOPS AND PEGS, AND ORDER OF PLAY IN ACCORDANCE WITH THE OFFICIAL LAWS (1928) OF THE CROQUET ASSOCIATION

Only those portions in heavy outline need be marked on the ground. The order of making the points is indicated by the arrows

professional Croquet and Roque, below, but this setting is no longer authorized by the British Croquet association.)

Like most other games croquet is subject to alteration and amendment in its rules and laws, but finality seems to have been reached in regard to the setting, which has been in general use since 1922. Mallets may be of any size and weight, but the head must be made of wood only, except that metal may be used for weighting or strengthening it. The two end faces must be parallel, of wood only, and identical in every respect, and each face may have a rounded edge which shall not be considered part of the face. A player may not change his mallet during a turn, except in the case of bona fide damage. The balls must be  $3\frac{1}{8}$  in. in diameter and of even weight, not less than  $15\frac{1}{4}$  oz. nor more than  $16\frac{1}{4}$  oz. The hoop or peg next in order for every ball at the commencement of a turn is distinguished by a clip the colour of the ball.

The object of the player is to score the points of the game by striking his ball through each of the hoops and against the peg in the proper order, and the side wins which first succeeds in scoring all the points with both the balls of the side. Each player starts in turn from either of the balk lines. If he fails either to make a point or to roquet (*i.e.*, drive his ball against) another ball in play, his turn is at an end, and the next player in order takes his turn.

If he succeeds in scoring a point, he is entitled to another stroke; he may then either attempt to score another point, or he may roquet a ball. Having roqueted a ball (provided he has not already roqueted the same ball in the same turn without having scored a point in the interval) he is entitled to two further strokes: first he must take croquet; *i.e.*, he places his own ball—which from the moment of the roquet is dead or in hand—in contact with the roqueted ball on any side of it, and then strikes his own ball with his mallet, being bound to move or shake both balls perceptibly. (If at the beginning of a turn the striker's ball is in contact with another ball, a roquet is held to have been made and croquet must be taken at once. If when taking croquet either ball should cross the boundary it must be replaced on the yard line opposite the point at which it did so; but balls passing the boundary at a point within the corner square must be replaced on the corner spot.)

After taking croquet the striker is entitled to another stroke, with which he may score another point, or roquet another ball not previously roqueted in the same turn since a point was scored; or he may play for safety. Thus, by skillful alternation of making points and roqueting balls, a break may be made in which point after point and even all the points in the game (for the ball in play) may be scored in a single turn, in addition in a peeling break to three or four points for the partner ball. (Peeling is a term used when the striker causes a ball, other than his own, to run a hoop in order; that ball is then said to have been peeled.) The chief skill in the game perhaps consists in playing the stroke called taking croquet (but *see* below on the rush). Care must be taken that both balls are moved or perceptibly shaken and that neither of them is driven over the boundary line, for in either event the player's next stroke is forfeited and his turn brought summarily to an end.

There are two main styles in playing croquet and the essential feature of each, whether to make a roquet or run a hoop, is that the eye, the ball and the object aimed at should form a vertical right angle. The upright style is played with a long mallet of about 39 in. The player faces the object to be hit, holding the top of the mallet with his left hand, the arm being close to the side. The right hand grasps the shaft lower down and is solely responsible for the necessary power of the strike, the left hand merely acting as the fulcrum of the swing.

Either the right or the left foot may be in advance, and should be parallel to the line of aim, the player's weight being mainly on the front foot. For the other style, commonly known as centre play, a shorter mallet of about 33 in. is used. The mallet is swung between the feet, the hands being close together and often overlapping. The centre style is undoubtedly more tiring and the strain on wrists greater, whereas the upright method, because it is less fatiguing, is far easier to maintain, especially on a slow lawn. In making a shot the ball should be hit in the centre and as

low down as possible with the exact middle of the mallet. The eyes must be concentrated on the spot and the head of the mallet drawn back slowly. This is the secret of all successful shots, either for roquets or hoop running; the more difficult the angle of the hoop, the slower the back swing—any jerking is fatal. The rush stroke is a roquet and is used to drive the pilot ball some distance; the ball must be hit full in the face for a straight rush. The hands and mallet should be kept down and should follow well through. True hitting should be aimed at, not force. The roll is a croquet stroke in which both balls are rolled along the same distance and is attained by standing well forward with the hands in front of the head of the mallet. The stroke is not a hit, but a sweep.

The pass roll is the most difficult of all, as unless it is played firmly and with deliberation the mallet will hit the ball twice and the stroke will be a foul. The stance is similar to that for the roll, but the ball is hit higher up and the curtailed back swing is more vertical, resulting, if the stroke is smooth, in the player's ball's passing the other ball. The split shot is utilized when two balls are to be driven in opposite directions. The player lines the balls so that they point in the direction that the croqueted ball is to travel, then plays the stroke facing the midway between that point and where his ball is being directed. The angles are the same as in billiards, though it is impossible to obtain an absolute right angle. The stop shot is also analogous to billiards, the object being to drive the croqueted ball a long distance and to keep the striker's ball back. The striker stands farther behind than usual, hitting the ball very near the bottom of the face of the mallet with a short, sharp hit. Taking off is a croquet shot and consists in taking off from a ball which is to be left behind and merely shaken to another ball or given spot on the lawn.

A first-class croquet lawn should be as level as possible with a true and consistent surface; no obstacle to an all-round break is therefore present other than the player's lack of skill. If games were won by all-round breaks alone, however, much of the interest would be missing. The picking up and assembling of the balls and the laying of a break at the conclusion of a turn generally require infinitely more skill and thought than the somewhat automatic execution of a three- or four-ball break. The main principle in either three- or four-ball breaks is always to keep the balls in a straight line and sweep them, as it were, along the path of direction. The chief secret of break making is correctly rushing the pilot ball with the aid of which the hoop has been made to the right spot after running it; by doing so the next shot is made easy, and the approach to the following hoop will become a short straight stop shot, ensuring a good position for hoop running. This positioning is the hallmark of first-class players. During a three-ball break the player must keep in mind the earliest and safest opportunity for bringing the fourth ball into play, for though it may be relatively simple to continue with only three balls it is impossible to finish the break satisfactorily unless all four balls are in command.

Tactics play an important part in the game. They must be based upon the player's knowledge of his own skill and what he knows of his opponent's strength or weakness. Broadly speaking, two points must be considered before shooting: what will be gained if the roquet is successful and how it will affect the opponent's next turn if unsuccessful. Although either ball of a side may be played, much can be done to compel the opponent to shoot with his forward ball. It can be left near the hoop of the player's backward ball, and in many other ways it is possible to influence the progress of the adversary.

**Lawn Croquet.**—The layout of the field for lawn croquet is determined by the available space. The playing field consists of nine wire hoops, or wickets, and two wooden stakes (*see fig. 2*). No layout should be more than 40 ft. wide and 75 ft. long (smaller than the British 28 by 35 yd. or 84 by 105 ft.). The

boundary line is usually 7 ft. from the end wickets and 5 ft. from the side wickets. In placing the wickets in the playing field, the first wicket is placed a mallet-handle length from the starting stake and the same distance is measured from the first wicket to the second wicket.

The same measurements are used at the other end of the playing field in placing wickets 6 and 7. The other five wickets are placed in accordance with the space available. The centre wicket (4), is placed in the centre of the playing field. The side wickets, 3, 5, 8 and 9, are placed at right angles from wickets 2, 6 and 4, and five feet within the boundary of the playing field. Each side has 32 points to make, 16 with each ball. The balls are of hardwood,  $3\frac{3}{8}$  in. in diameter, and are made in multicolours with stripes or in solid colours. The mallets are of hardwood, with heads 6 in. to 8 in. long, and with handles approximately 30 in. long.

The object of the game is for a player to make all or as many wickets as possible before giving his turn of play to his opponent. When a player has hit any other ball with his own he may take one more shot from where his ball lies; he may place his ball a mallet head's distance in any direction from the ball he has hit and take two shots; he may place his ball against the other, step on his ball with one foot and strike his ball firmly to drive the other away, and then take one additional shot; or he may place his ball against the other and drive both balls in the same direction or at any angle. A rule book is included in each set of croquet equipment. However, ground rules are established by the local players of each court, since the courts are largely based on the available space.

**Official Regulation Croquet.**—A more technical game of skill than lawn croquet, official regulation croquet has been developed by the organized croquet associations. It is played on a smooth hard-surface court with short mallets (approximately 15-in. handle) and hard rubber balls. An official, regulation-size court is 40 by 75 ft. with ten steel wickets,  $3\frac{3}{8}$  in. wide and 9 in. above the ground surface and two steel stakes, and is surrounded by a concrete boundary wall (see fig. 3). The two centre wickets, 4 and 12, are placed 18 in. apart, which makes the centre wicket more difficult to make than the other wickets. The hard-rubber balls are  $3\frac{3}{8}$  in. in diameter, weigh 12 oz. and are made in sets of four, red, white, blue and black.

The mallet heads are of hardwood or aluminum tubing, with a rubber tip on one end and a hard laminated plastic or aluminum tip on the other end. The size and weight of the mallets vary according to the desire of the players.

The object of the game is for a player to make all or as many wickets as possible before giving his turn of play to his opponent. A player has a hit, a roquet (a drive or hit against an opponent's ball) and a free shot to make a wicket before giving his turn of play to his opponent. A player's ball may hit another ball or all three balls before making a wicket or knocking his opponent's ball behind the wicket or out of position. A player is dead on a ball after a hit, until he makes a wicket or point, that is, he cannot hit the ball in successive hits, even upon his next turn of play, until he has made a wicket, or point. Professional players may use pool or billiard strategy in making carom shots, in which a player's ball hits the wall, rebounds, and hits another ball, balls or wickets. A carom shot is also known as a wall or bank shot. It is used by a player to knock an opponent's ball out of position when he is dead on the ball. It is also frequently used to get in position or to hit an opponent's ball when the latter's ball is

behind a wicket, stake or another ball. The wall or bank shot is used at all times when the player is unable to make a direct shot against his opponent's ball or through a wicket.

The game, which is played by two players (singles) or four (partners or doubles), is started by the players lagging, or shooting, from the centre of the court to the playing line. The player whose ball stops nearest the playing line has the first shot. The balls are then placed on the four corners of the court (see fig. 3). Partner's balls are placed diagonally opposite each other. The player who wins the lag for first play, places his ball at the starting end of the court and he has a choice of the sides of the court. All shots must be fair and distinct blows from the mallet. It is not permissible to push the ball with the mallet. The side or corner wickets are made in the direction of the centre wickets. The other wickets are made in the direction of play on the court. Coloured clip pins of red, white, blue and black are used for markers.

At the completion of a player's turn, he places a marker at the wicket for which he will aim at his next turn. Such markers are not absolutely necessary, since the player's ball designates the wicket for his next turn of play; the use of markers, however, prevents arguments and friction among the players. Games are decided by completed games, by a designated time limit or by a designated number of innings (a complete round of play by all players before their next turn of play).

FIG. 2.—UNITED STATES LAWN CROQUET COURT LAYOUT, SHOWING PLACEMENT OF WICKETS AND DIRECTION OF PLAY

FIG. 3.—PROFESSIONAL CROQUET COURT LAYOUT AND DIAGRAM OF PLAY  
Starting position of balls shown by filled circles

If the game is being decided by a completed game, the player who makes all the wickets and hits the two posts, or makes a possible score of 32 points first, is the winner. If a game is being decided by a designated time limit or innings, the length of time for the game (one to two hours) or the number of innings (9 to 15) is designated before the start of the game.

**Roque.**—This is a scientific version of croquet. The object of the game is the same as that of croquet.

An official regulation size roque court is 30 by 60 ft. and is octagon shaped (see fig. 4). The court has a hard surface and a solid concrete boundary wall. The court has ten  $\frac{3}{8}$ -in. diameter steel wire arches. The space between the arches is  $3\frac{3}{8}$  in. The arches are set rigidly in the ground and extend 8 in. above the surface of the court. There are two steel stakes,  $\frac{3}{4}$  in. in diameter, set rigidly in the ground at both ends of the court.

The balls are of hard rubber,  $3\frac{3}{8}$  in. in diameter, one red, one white, one blue and one black. The mallets have a solid head with a smooth face of laminated plastic or aluminum on one end and rubber on the other end, for hard and easy shots. The standard handles are 15 in. long; there is, however, no restriction as to the size or weight of the mallets. Court markers are of the same colour as the balls, red, white, blue and black.

Much scientific thought is given to the maneuvering of the balls through the arches and keeping the opponent's ball out of playing position by direct, roquet and carom shots.

A game is started by lagging as in croquet. All four balls are placed on the corners nearest the centre of the playing line (see fig. 4), with the partner's balls diagonally opposite each other

FIG. 4.—ROQUE COURT LAYOUT AND DIAGRAM OF PLAY  
Starting position of balls shown by filled circles

The playing ball and the next in sequence are placed at the head of the court. The player who has won first, attempts to hit a ball down the line and to maneuver the balls in position for making the arches. If he is successful, he may make one arch, a number of arches, or all 32 points before giving his turn of play to his opponent. A player making 32 points in one turn of play before giving the balls to his opponent is known as a rover. Games are decided by completed games, by a designated time limit, or by a designated number of innings. The player making all arches and hitting the two posts or making all 32 points first is the winner of a completed game. If playing innings, the player having the greatest number of points at the close of a designated number of innings (usually 15), is the winner. If playing time limit (usually two hours), the player having the greatest number of points at the designated time is the winner. A player may become a winner at any inning or at any time limit if he makes the complete 32 points before the designated number of innings or designated time limit.

(M. T. Y.)

**CROSBY, FANNY** (1820–1915), originally Frances Jane Crosby, U.S. writer of hymns widely sung in her day, was born at Southeast, Putnam County, N.Y., on March 24, 1820. She lost her sight at the age of six weeks as the result of negligence on the part of a doctor. In 1835 she entered the Institution for the Blind in New York city and was teacher of English there from 1847 to 1858. In her youth she published several volumes of poetry. In 1858 she married her pupil, the blind musician, Alexander Van Alstyne, and six years later began writing hymns. From then until her death on Feb. 12, 1915, at Bridgeport, Conn., she composed about 6,000 hymns. "Safe in the Arms of Jesus" was her best-known hymn. Several became known in England and were translated into foreign languages. She wrote her memoirs in 1903 and 1906.

**CROSBY**, a residential town and municipal borough of Lancashire, Eng., 7 mi. N.W. of Liverpool. The name is of Norse origin. The borough was formed in 1937 from the former urban districts of Great Crosby and Waterloo with Seaforth. Pop. (1961) 59,166. Area 11 sq.mi. (including 3½ sq.mi. of seashore). Crosby hall has been the home of the Blundell family for many centuries. At Seaforth house (1813), now demolished, lived Sir John Gladstone, father of the prime minister William Ewart Gladstone.

The borough is the home of the Merchant Taylors' schools (the boys' founded in 1620 and girls' in 1888), and of the Waterloo rugby football club (1882). Coursing (Waterloo cup) takes place at Altcar, a few miles northeast of the borough.

**CROSIER** (PASTORAL STAFF), a crook-shaped staff, a liturgical symbol of a bishop's or abbot's office. See VESTMENTS, ECCLESIASTICAL.

**CROSS, HARDY** (1885–1959), U.S. professor of civil and structural engineering, who revolutionized the calculation of moments in a continuous framework, was born at Farmers Delight plantation, Nansemond county, Va., on Feb. 10, 1885. After some years of teaching, interspersed with periods spent gaining engineering experience, he was appointed professor of structural engineering

at the University of Illinois in 1921. In 1937 he was appointed professor of civil engineering at Yale, becoming professor emeritus on his retirement in 1951. He died at Virginia Beach, Va., on Feb. 11, 1959.

Cross's outstanding contribution to the theory and practice of structural engineering lay in his method of calculating moments in the members of a continuous framework. By its use, calculation can be carried to any required degree of accuracy by successive approximations, thus avoiding the immense labour of solving simultaneous equations that contain as many variables as there are rigid joints in the frame. The method, first announced in 1930 in a paper to the American Society of Civil Engineers, is known as the moment distribution method, or simply the Hardy Cross method.

Cross also successfully applied his mathematical methods to the solution of pipe network problems that arise in municipal water supply design; these methods have been extended to other pipe networks such as gas pipeline systems.

Cross was awarded honorary doctorates by several U.S. universities, and medals by a number of U.S. professional bodies. In 1958, as a recognition of the world-wide significance of his work, the (British) Institution of Structural Engineers awarded him its gold medal.

(S. B. HN.)

**CROSS, RICHARD ASSHETON CROSS, 1ST VISCOUNT** (1823–1914), English statesman, the greatest home secretary of the 19th century, was born at Red Scar, near Preston in Lancashire, on May 30, 1823. He was educated at Rugby, where one of his school friends was Edward Stanley, afterward 15th earl of Derby and a future cabinet colleague, and at Trinity college, Cambridge. He was called to the bar by the Inner Temple in 1849 and quickly built up a large practice in Lancashire. He sat in the house of commons as Conservative member for Preston from 1857 to 1862, when business commitments forced him to give up his seat. He returned to parliament in 1868, defeating Gladstone for South-West Lancashire. During the whole of this time he was very active in local government.

In 1874 Disraeli brought Cross into his cabinet as home secretary despite his complete lack of ministerial experience, describing this action to Queen Victoria as an "almost unexampled mark of confidence." It was a key position, for the whole success of Disraeli's policy of social reform depended upon it. In 1875 Cross carried the Artisans' Dwelling act, which empowered municipal authorities to acquire and demolish slums and to build, own and let their own housing; the Public Health act; two acts reinterpreting Gladstone's trade union legislation of 1871 in a sense more favourable to the unions; and a Factory act. Other measures brought in by Cross codified existing legislation governing factories and the sale of food and drugs, and provided for the transfer of prison management from local to central government and for the preservation of open spaces near large towns. If this legislation, showing that "Tory democracy" was no mere phrase, was inspired by Disraeli, it is nonetheless true that Cross was more than a mere executor of detail. He shaped policy too.

Between 1880 and 1885 Cross's star began to wane. He was on bad terms with Lord Randolph Churchill and, although he was home secretary in Lord Salisbury's fleeting government of 1885, he was sidetracked to the India office from 1886 to 1892 and elevated to the peerage. He was lord privy seal from 1895 to 1900. He died near Broughton-in-Furness, Lancashire, on Jan. 8, 1914.

There was nothing brilliant about Cross, but he was efficient and shrewd, essentially a man of business rather than a debater or orator, and he achieved more than many people with far greater superficial talents.

(R. N. W. B.)

**CROSS**, the principal symbol of the Christian religion, recalling the crucifixion (q.v.) of Jesus Christ and the redeeming benefits of his passion and death. The cross is thus both a sign of Christ himself and of the faith of Christians. In ceremonial usage, marking a sign of the cross may be, according to the context, an act of profession of faith, a prayer, a dedication or a benediction.

There are four basic types of iconographic representations of the cross: (1) the *crux quadrata*, or Greek cross, with four equal

arms; (2) *crux immissa*, or Latin cross, whose base stem is longer than the other three arms; (3) *crux commissa*, in form of the Greek letter tau, sometimes called St. Anthony's cross; and (4) *crux decussata*, named from the Roman *decussis* or symbol of the

TYPES OF CROSSES

however, to their caution about pictorial images of the cross the Christians frequently used the ceremonial gesture of signing the cross to fend off demonic spirits. Tertullian said:

At every forward step and movement, at every going in and out, when we put on our clothes and shoes, when we bathe, or sit at table or light the lamps, or go to bed or sit down, and in all the ordinary actions of daily life, we trace upon the forehead the sign of the cross.

Hippolytus reminded Christians that this signing against the devil was a reminder of the "seal" of their baptism, when the bishop laid his hands upon them, anointed them with chrism and signed their foreheads after they had come out of the baptismal water.

The zealous sect of Montanists frequently inscribed crosses on their funerary monuments in Phrygia, but elsewhere examples of indisputably Christian crosses on tombs or objects are very rare. In the Roman catacombs, a Greek cross embellishes an inscription in the Lucina crypt of St. Calixtus, a tau cross is inscribed on a graffito in the subterranean mausoleum of the "Innocents" at St. Sebastian, and a Latin cross appears in a fresco of the (probably Gnostic) Hypogeum of the Aurelii on the Viale Manzoni. None of these crosses is earlier than the end of the 2nd century.

Much debated is the significance of a T-shaped cross marked in the plaster of a house at Herculaneum (destroyed in A.D. 79), whether it indicates the private oratory of a Christian or is merely the trace of a wall bracket or shelf. Equally enigmatic are the origin and meaning of the Sator-Rotas magic square, of which the earliest examples have been found at Pompeii. In any case, it is certain that Christians had much to do with the wide diffusion of the square, discerning in it among other things a cryptogram of the cross:

**The Cross After Constantine.**—Constantine's conversion to Christianity, on the eve of his victory over Maxentius in 312, was related to his vision of the "heavenly sign" of the cross which he believed to be a divine pledge of his triumph. Though the accounts of his vision as recorded by Lactantius and Eusebius differ in details, there is no question that Constantine promoted, as symbols of the Christian faith, both the cross and the chi-rho monogram of the name of Christ. He exhibited them, both separately and in combination, upon his military standards and armour, his statues and his coins, and in the decorations of his palaces. In particular, the remodeling of the standard of the troops, the so-called *labarum*, in the form of a cross surmounted by the chi-rho was symbolic of his aim to place the empire under the protection of the saving sign of Christ. The symbols became immensely popular on Christian *objets d'art* and funerary monuments, notably the so-called "passion sarcophagi" that date from c. 350 onward (a celebrated one is the Lateran museum sarcophagus no. 171); and impressive mosaics of the monogram set in a starry sky adorned a wall niche in Santa Costanza at Rome, of the early 4th century, and ceilings in the baptisteries of Naples and Albenga of the 5th century.

A primary stimulus for devotion to the triumphal trophy of the cross was the erection at Constantine's initiative of the basilica and rotunda at Jerusalem over the supposed sites of the crucifixion and resurrection. Eusebius described the discovery of the Holy Sepulchre and the layout and adornment of these buildings. No reference to any finding of the true cross, however, is made by Eusebius or by the pilgrim of Bordeaux (A.D. 333). But Cyril of Jerusalem, in lectures to catechumens about 350, mentioned the existence of the wood of the true cross, pieces of which had been

numeral 10, also known as St. Andrew's cross. Tradition favours the *crux immissa* as that on which Christ died (cf. Matt. xxvii, 37), but some believe that it was a *crux commissa*. The manifold variations and ornamentations of processional, altar and heraldic crosses, of carved and painted crosses in churches and graveyards, etc., are developments of these four types.

**Pre-Christian Crosses.**—Cross forms were used as symbols, religious or otherwise, long before the Christian era in almost every part of the world, though it is not always clear to what degree they may be simply marks of identification or possession or may bear significance for belief and worship. Two pre-Christian cross forms have had some vogue in Christian usage. The ancient Egyptian hieroglyphic symbol of life—the *ankh*, a tau cross surmounted by a loop and known as *crux ansata*—was adopted and extensively used on Coptic Christian monuments. The swastika—called *crux gammata*, its form being composed of four Greek capitals of the letter gamma—is marked on many early Christian tombs as a veiled symbol of the cross. This symbol had a wide diffusion before the Christian era in Europe, Asia and America, and is commonly thought to have been an emblem of the sun or fire, and hence of life. (As revived in Nazi Germany, from the mistaken fancy that it was a Nordic symbol, it was intended as both a substitute for and a caricature of the Christian cross.)

Many Jewish ossuaries dating from the 1st century A.D. have been discovered in Palestine bearing tau crosses, either carved or marked in charcoal. Some scholars consider these to be the oldest identifiable signs of Christian burial; others consider them to be Jewish eschatological symbols, based upon Ezek. ix, 4, the sign of the letter *taw* (the last letter of the Hebrew alphabet, corresponding to the Greek tau), marked on the forehead of the righteous for protection in the coming judgment. But the early Christians, as both Tertullian and Origen indicate, understood the Ezekiel passage as a prophecy of the sign of the cross. It may be that the ossuary marks have no religious significance and are merely identification signs.

**Earliest Christian Crosses.**—Before the peace of the church under Constantine, Christians were extremely reticent about the portrayal of the cross, lest too open a display of it expose them to ridicule or danger. In general, they preferred to employ a cryptic substitute (*crux dissimulata*), of which the commonest examples on burial slabs are the anchor, ax, trident and swastika. Christian writers also saw the "sign of the cross" hidden in many natural phenomena and objects: shipmasts, plows and other tools, military standards (*vexilla*), birds on the wing and the human body standing with arms extended at prayer (the *orans*). In contrast,

"distributed all over the world," and a letter of Cyril to the emperor Constantius II related the apparition of "a gigantic cross of light in the sky above holy Golgotha" on May 7, 351.

By the end of the 4th century, Ambrose, Rufinus and others knew the tradition of the "invention" or finding of the true cross by Constantine's mother, Helena, on her visit to the holy places in 326. According to the legend, three crosses had been found deep in the ground, together with the superscription placed over Christ's head and the nails with which he was crucified. A miraculous cure had identified the true cross. Helena sent her son two of the nails, one in a diadem, the other in a bridle. The basilica of Santa Croce in Rome, built in a palace of Helena, exhibits to this day a piece of the cross and the superscription plaque, and one of the nails is said to be preserved in the iron crown of Lombardy, venerated at Monza.

On a rocky mound of the open court between the basilica and rotunda of the Holy Sepulchre, a large commemorative metal cross was erected, which Theodosius II in 417 encased with gold and precious jewels. A representation of this cross, as it appeared c. 400 with the buildings around it, may be seen in the apse mosaic of Santa Pudenziana in Rome. (The cross, however, may be later than most of the mosaic, a restoration having been carried out late in the 8th century.) This cross inspired many artistic representations of a jeweled or flowering cross, among which may be named the cupola mosaics of the mausoleum of Galla Placidia at Ravenna, and the church at Casaranello, and the apse mosaic of S. Apollinare in Classe at Ravenna; and among smaller objects, a 5th-century ivory cover of the Gospels-book in the Milan cathedral.

Many representations occur on the little bottles (ampullae) which pilgrims to the Holy Land brought home filled with consecrated oil from the lamps of the sacred places; a famous collection of them is in the cathedral treasury at Monza. Persons fortunate enough to obtain filings from the true cross kept them in caskets (*staurothecae*) of precious metal, ivory or enamel, often of a cross shape and hung from a chain around the neck, thus originating the pectoral cross (*encolpion*), which in modern times has become a distinguishing insignia of prelates. (Other relics, of course, were deposited in these crosses and caskets, and pectoral crosses were not always reliquaries.) The Museo Sacro of the Vatican possesses several precious examples of these crosses, as does also the Victoria and Albert museum in London, ranging in date from the 6th to the 9th centuries. Among the treasures of Durham cathedral is the pectoral cross buried with St. Cuthbert in 687, a gold cross with cloisonné work inset with garnets, generally considered to be English work of the 7th century.

Two festivals of the cross commemorate the Jerusalem traditions. The more ancient one, a major feast of the Eastern Churches, is the Exaltation of the Holy Cross (Holy Cross day) on Sept. 14, which goes back to the dedication of the Church of the Holy Sepulchre in 335. The feast was introduced in the west in the 7th century, when it had become doubly famous by the

CRUX IMMISSA. DETAIL FROM THE MOSAIC VAULT OF S. APOLLINARE IN CLASSE, RAVENNA, ITALY, 6TH CENTURY

emperor Heraclius' recovery and restoration of the true cross in 629, which the Persians had taken when they captured Jerusalem in 614. In the same century a feast of the Invention of the Holy Cross on May 3 appears in calendars of Gallican service books; this feast was added to the Roman calendar in the 9th century.

Of the services developed at Jerusalem around the holy places, those of Holy Week deeply affected the pilgrims. One of these, the veneration of the relic of the cross on Good Friday, was widely disseminated, and survives today in the Good Friday rites of the Roman Catholic Church, as the Veneration of (or Creeping to) the Cross. This devotion is mentioned in the late 4th century in the account of the pilgrim Etheria and by the poet Prudentius. A gift of a relic of the true cross made by Justin II to the Abbey of the Holy Cross in Poitiers in 569 inspired the famous hymns of the cross by Venantius Fortunatus, the *Vexilla regis* and *Pange lingua gloriosi*, used in the Roman liturgy. During the iconoclastic controversy of the 8th-9th centuries, the propriety of the veneration of the cross, as of other religious images, was debated in both the Eastern and Western churches.

**Crucifix.**—For several centuries after Constantine, Christian devotion to the cross centred in its indication of the victory of Christ over the powers of evil and death. Indeed, the Fathers of the Church often explained the cross as a cosmic sign of Christ's universal dominion—its four projections reaching out to embrace and bring under his subjection "the breadth and length and height and depth" (*cf.* Eph. iii, 18) of all creation. Realistic portrayal of his suffering was avoided. The earliest "crucifixion" scenes known depict Christ alive, with eyes open, standing rigid against the cross with his arms straight out, his Godhead manifest, even

though he is pierced and dead in his manhood. Two types may be distinguished: an "Eastern," in which Christ wears a long sleeveless tunic (the *colobium*), and a "Western," in which he is nude except for a loin girdle. The Eastern type, created in Palestine, is best represented in the late 6th-century miniature of the *Rabula Codex* of the Gospels, now in Florence; a mural in Santa Maria Antiqua at Rome; and a painted wooden reliquary from the Lateran *Sancta Sanctorum*, now in the Museo Sacro of the Vatican. Two early examples of the Western type are an ivory casket in the British Museum and a wooden panel on the doors of Santa Sabina at Rome. The date of these is disputed, but they cannot be earlier than the 5th century. The eastern type is found in Irish miniatures, but the other type prevailed in the west from the Carolingian period.

By the 9th century, artists began to stress more and more the realistic aspects of Christ's suffering and death. In the east, the struggle with iconoclasm led to acceptance of an iconographic portrayal of a nude, dead Christ, in reaction to the monophysite tendencies of the iconoclasts to overstress the Godhead of the Son of God and hence to reject the propriety of figured representations of his humanity. But the Eastern Church has nonetheless maintained, since the iconoclastic controversy (*q.v.*) a strong aversion to sculptured portrayals in the round. The churches of the west have never shown such caution.

The Western approach to the cross, stemming particularly from St. Augustine, has been less concerned with the cosmic and creedal connotations than has the Eastern. It has been more subjective, personal and mystical, emphasizing the cross as the supreme expression of the divine charity, and—during the medieval period in particular—finding in the suffering of the Redeemer remedy for sin and consolation for the tragedy of life. Western portrayals of the crucifixion, whether painted or carved, exhibited an increasing finesse in the suggestion of pain and agony. Romanesque crucifixes, with all their stark simplicity, show often a royal crown upon the head of Christ; but the later Gothic type replaced it with a crown of thorns. The ultimate horror of Christ's agony is perhaps brought to a climax in Mathias Grünewald's Isenheim altar paintings (completed *c.* 1515–16), in the Colmar museum. Renaissance artists tended to soften and humanize the Gothic realism of the crucifixion; baroque artists gave the scene great drama.

A new iconography inspired by ancient models emerged in the 20th century, especially for crucifixes in liturgical settings: the *Christus Rex*, in which Christ on the cross is crowned and vested as a king and priest, and the marks of his suffering are much less prominent.

**Other Medieval Crosses.**—The custom of carrying a cross before church processions, which can be traced back to the 6th century, may have been borrowed from the court ceremonial of the Roman emperors. An ivory from Constantinople, now in the cathedral of Trier, shows a procession for the translation of relics led by the emperor and empress, the latter carrying a cross. Bede relates that when Augustine and his fellow monks entered Canterbury in 597 a silver cross and a banner with an icon of Christ were

BY COURTESY OF THE BIBLIOTHEQUE NATIONALE, PARIS

CRUX COMMISSA, ILLUMINATED INITIAL FROM THE DROGO SACRAMENTARY, 9TH CENTURY: IN THE BIBLIOTHEQUE NATIONALE, PARIS

borne in their procession. Seven silver processional crosses, one for each region of the city, are mentioned in the 7th-century *Ordines* that describe the processions before the papal station masses at Rome. In medieval times the processional cross was placed near or behind the altar during the celebration of mass; and from the 13th century onward, the cross itself came to be detached from its staff and placed directly on the altar. Not until the misal of Pius V, however, was the placing of a cross or crucifix on the altar a requirement. From the 13th century also dates the privilege of archbishops to have a cross carried before them within the bounds of their province. In such processions, the image of the crucified Christ is customarily turned backward to face those who follow it. In the conventions of medieval iconography, an archbishop is distinguished from a bishop by a cross staff which he holds instead of the bishop's crosier.

From the earliest period of Christianity in Ireland, crosses were engraved on standing stone slabs—a means of Christianizing an ancient pagan cult of the standing stone. It was also the custom of Irish missionaries to erect crosses of wood (later of stone) to mark preaching stations, and similar crosses were set up beside their monasteries. From these traditions evolved the impressively carved free-standing crosses of stone that are such a distinctive feature of Celtic-Christian culture. These crosses have a circle about the intersection of the two beams—possibly suggested by the chi-rho monogram in a circle—and the carvings display not only the crucifixion, but scenes from the Old and New Testaments and the lives of the saints. The oldest ones in Ireland date from the 9th century, among the most famous being those of Muiredach, Monasterboice, Kells, Durrow and Clonmacnoise. From Iona the Celtic stone crosses were introduced to Scotland and Northumbria and thence to other parts of Britain. Those at Bewcastle and Ruthwell (near Dumfries), commonly dated to the late 7th century, are the most celebrated. Their carvings show marked stylistic influence from the art of the Mediterranean world. The Ruthwell cross bears a runic inscription with lines from the Anglo-Saxon poem *The Dream of the Rood*. Crosses such as these probably provided the inspiration in later medieval times for the erection of stone crosses in market places, churchyards and memorial sites, marking the stages of funeral processions of eminent personages.

ALFANI

CHI-RHO CROSS FROM THE PASSION SARCOPHAGUS NO. 171 IN THE LATERAN MUSEUM, ROME; 3RD-4TH CENTURY

The crusaders received the sign of the cross as a symbol of their vow to recover the true cross at Jerusalem from the infidel, and the crusading movement thus gave impetus to the use of the cross as a heraldic emblem. Best known is probably the Maltese cross of the Hospitallers, a white cross of eight points on a black ground.

Heraldic crosses also appear on the ensigns of Christian countries: the English cross of St. George is a plain red cross on a white ground; the Scottish cross of St. Andrew is a plain diagonal white cross (a saltire) on a blue ground; and the Irish cross of St. Patrick is a plain diagonal red cross on a white ground. (See also *HERALDRY*.)

**The Cross in Reformed Churches.**—The Lutherans have generally retained the ornamental and ceremonial use of the cross and crucifix. The Calvinistic churches on the other hand consistently refused them until the 20th century, when ornamental crosses on church buildings, and even on communion tables, began to make an appearance. The Church of England would probably have followed the Lutheran example but for the determined opposition of Puritan prejudice. The English Church, however, stubbornly retained the ceremonial signing with the cross in the rite of baptism, and canon 30 (1604) presents a vigorous defense of the custom. Since the Tractarian movement of the mid-19th century, Anglican churches throughout the world have witnessed a revival of the use of the cross, and there are few parishes today without at least altar and processional crosses. Likewise the ceremonial use of the sign of the cross in giving absolution and benediction is common. The crucifix, however, is almost entirely confined to private devotional use.

(M. H. SH.)

**CROSSBOW**, or arbalest, the leading hand missile weapon of the middle ages prior to the introduction of firearms. Consisting of a short bow fixed transversely on a wooden stock, it had a groove to guide the missile and a trigger to release it. The wooden crossbow could be drawn by hand, but the most effective type had a steel bow so stiff as to require a small winch. The stock terminated in a stirrup that enabled the soldier to hold the weapon in position with his foot while operating the winch with both hands. A square-headed bolt known as a "quarrel" was the standard ammunition. About ten inches long, its maximum range was 300 yd. It could be fired with considerable accuracy and was capable of piercing all but the stoutest body armour.

Not much is known about the origins of the crossbow but it is likely that it evolved in Italy early in the middle ages. At any rate, the Italian city states were among the first to adopt the weapon, and Genoese crossbowmen hired out as mercenaries to all the armies of Europe. As the name "arbalest" implies (from the Latin *arcu*, "bow," and *ballista*, "engine of war"), it was simply a small ballista bearing the same relation to that engine of war as the musket to the cannon. Such was its effectiveness, as compared to conventional bows of the age, that several popes interdicted the crossbow (except against infidels) on the ground that its use constituted an atrocity. Nevertheless, it proved to be the most effective hand missile weapon of the crusaders in their battles with the Saracens. Richard the Lionhearted won the battle of Arsuf (1191) during the third crusade largely because of the havoc wrought among Saladin's forces by Christian crossbows. By the late 13th century the master of the crossbowmen had become a great dignitary in France and Spain, and in the latter country the weapon was used by an elite corps of men of upper-class birth, who, with their gay apparel, were a picturesque feature of continental armies of the period.

When the relative merits of crossbow and English longbow were tested on the field of Crécy (1346) the longbow appeared to advantage. But the poor showing of the Genoese crossbowmen may be charged chiefly to the inept tactics of their employers, the French knights. Actually the crossbow had several points in its favour: its ammunition was cheaper and less bulky; it could be fired from a reclining position; and its compactness made it better suited to firing from behind a wall or parapet. On the debit side, the crossbow was slower and less accurate, though it must be remembered that the English archers had no equals in Europe.

Even after the advent of firearms the crossbow held its own until the introduction of the arquebus (*q.v.*) in the late 15th century. Its merits have been demonstrated in the 20th century by sportsmen who have used it successfully for hunting large game. Enough interest was shown in the United States during the 1950s so that the crossbow was manufactured and sold commercially on a small scale.

See Sir Ralph Payne-Gallwey, *The Cross-bow* (1903).

(LN. MS.)

**CROSSETTE**, in architecture, a projection at the upper corners of the architrave of an opening, when the top or lintel projects on either side beyond the width of the architrave below. In this sense it is synonymous with "ancon." The form developed through primitive construction in which the lintel stone was much wider than the opening, but remained commonly in use in all the classic styles. The term also applies to a projection on a voussoir which fits into a corresponding space in the adjoining voussoir.

**CROSSOPTERYGIAN**, the name of a major group (*Crossopterygii*) of bony fishes, prominent in Upper Paleozoic (120,000,000-year period initiated 320,000,000 years ago) freshwater deposits and important as the group from which land vertebrates appear to have been derived. The group, except for a single aberrant survivor, *Latimeria*, has been long extinct (see *COELACANTH*).

The typical crossopterygians, the Rhipidistia, flourished in the Devonian but then declined in importance and disappeared shortly after the opening of the Permian. The skull roof has a complex pattern of bones, most of which can be compared with those present in early land animals; similar comparisons can be made in jaw and palate structure. The brain case is distinctive in that it is completely divided into front and back halves and has a large canal, housing an anterior prolongation of the notochord, beneath the posterior segment—features not present in typical land animals (or, indeed, in other fishes) and once thought to debar crossopterygians from the ancestry of higher vertebrates; however, very ancient fishlike amphibians (*q.v.*; *Ichthyostegalia*), described from the late Devonian of Greenland, have the notochordal canal and traces of a brain-case division.

The paired fins, where known, have a skeleton showing a single element in the proximal segment (closest to the body), two in the second and an irregularly branching arrangement beyond—a pattern from which the vertebrate land limb can be readily derived. Lungs and internal nostrils were presumably present. Although no specific form can be identified as actually ancestral, it is reasonable to believe that the rhipidistian crossopterygians included

PARTS OF THE CROSSBOW

(A) stirrup for reloading; (B) steel bow; (C) slot for guiding missile; (D) winch for retracting steel bow

the forebears of the amphibians and hence of all land vertebrates.

In the Late Devonian appeared the Coelacanthini, a specialized side branch of the crossopterygians, various members of which took to the sea and have been identified in the fossil record as late as the Cretaceous period. The *Latimeria* belongs to this group.

(A. S. RR.)

**CROSS RIVER**, in Nigeria, rises in the mountains of southern Cameroon and flows in a great arc northward round the Oban hills before reaching its estuary. Its total length is about 300 mi., and during the rains it forms an important routeway. River steamers can reach Itu at all seasons, Ikom from June to November and Mamfe during August and September. The lower stretches of the river are bordered by mangrove swamp, but the upper reaches flow through high forest, which includes mahogany and the ubiquitous oil palm.

The estuary of the Cross river is really the drowned lower part of its valley. It has been suggested that the Benue originally reached the sea at this point, an explanation which would help to account for the broad plains of the lower Cross basin and the low northern watershed. The estuary is the only major break in the Nigerian coast line which is not impeded by a sand bar across its mouth, and this fact, coupled with a moderate tidal range (9 ft. at Calabar), makes the Cross river the finest natural port approach in Nigeria. Unfortunately the remote position of Calabar and the absence of railway connection with the rest of Nigeria have neutralized these advantages.

(J. C. PH.)

**CROSSWORD PUZZLE**, the most popular form of word puzzle. A crossword puzzle consists of a diagram, usually rectangular, divided into blank (white) and canceled (black, shaded or crosshatched) squares. This is accompanied by two lists of numbered definitions, one for the horizontal and the other for the vertical words, the numbers corresponding to identical numbers on the diagram. Into each of the blank squares of the diagram a certain letter of the alphabet is to be inserted, forming the words fitting the numbered definitions. In properly keyed puzzles most of the letters form a part of two interlocking words, one running down and one across, and when the proper solution is fitted all the words cross each other, or interlock, which fact gives the puzzle its name.

The first crosswords appeared in England during the 19th century. They were of an elementary kind apparently derived from the word square, a group of words arranged so the letters read alike vertically and horizontally, and printed in children's puzzle books and various periodicals. However, it was in the United States that the puzzle developed into a serious adult pastime. The first modern crossword puzzle was published on Dec. 21, 1913 in the *New York World's* Sunday supplement, *Pun*. It appeared as only one of a varied group of mental exercises, but it struck the fancy of the public so favourably that the desire for crosswords spread immediately. By 1923 they were being published in most of the leading newspapers and were the most talked of form of entertainment in the United States. Within a few months the craze reached England to take it by storm. In the United States and England the impetus supplied by the initial surge of popularity made the puzzles first a national fad and then a well-entrenched habit. Almost all daily newspapers in the United States and Great Britain have a crossword feature of some kind.

Crosswords in multiple forms are found in almost every country and language. Scholars have even gone so far as to adapt them into Latin. Advocates claim the puzzles are both a pastime and an interesting means of improving the vocabulary. Though the majority of puzzles are confined to symmetrical patterns of shaded or blacked-out squares (see fig.) within a rectangle, there are many variations. These include (a) an asymmetrical scattering of squares; (b) a plain diagram with no squares canceled and the ends of words marked simply by a thick line; (c) isolated but quite successful examples of pictorial designs, either in outline containing the diagram, or in line inside the diagram, or a combination of both; (d) diagramless puzzles with no clue given to the position or length of the words.

The general type of crossword has also been subject to variation. Some puzzles employ abstruse definitions, puns and anagrams.

#### ACROSS

- 1 Incarcerate.
- 5 Royal name in France.
- 10 Distort.

#### SAMPLE CROSSWORD PUZZLE AND SOLUTION

A number of words in one puzzle may bear upon some announced theme such as music, sports, literature or geography. Many of the puzzles in this category are difficult and serve as the medium for a generally recondite examination of the theme. Again, some clues

will be omitted altogether, but a direction be given that the words thus neglected belong to a particular class: jewels, for example, or the words in a quotation. Sometimes every word will have some given prefix, suffix, or part in common, and only the rest of the word will actually fill the spaces in the diagram; (cat)alepsy, (Cat)hay, etc.; unc(tion), cap(tion), etc.; qu(it)e, cr(it)ic, etc.

Among well-known series of collections have been the *Cross Word Puzzle Books* and *Crossword Puzzle Omnibuses*, edited by Margaret Petherbridge Farrar; the *Giant Crossword Puzzle Books*, edited by A. M. Lownsbury; *Double-crossics*, edited by E. S. Kingsley and Doris Nash Wortman; and collections of puzzles that have appeared in the *New York Times*, the *London Daily Telegraph*, the *Manchester Guardian*, the *New Statesman* and the *Edinburgh Scotsman*.

**BIBLIOGRAPHY.**—C. H. R. Thorn, *Complete Crossword Reference Book*, rev. ed. (1956); W. and R. Chambers, Ltd., *Crossword Aid for Solvers and Setters* (1956); E. M. Lane, *Rapid Crossword Solver* (1958). (G. E. Lr.; M. Dc.)

**CROCHET:** see MUSICAL NOTATION.

**CROTHERS, RACHEL** (1878–1958), U.S. playwright and one of the few women directors in the history of the American stage, was born in Bloomington, Ill. She died at Danbury, Conn., on July 5, 1958. Her professional career began in 1906 with the success of her first full length play, *The Three of Us*. For the next three decades, until *Susan and God* (1937), Broadway saw an average of one new Crothers play each year, the majority of them popular and critical successes, an achievement unequalled by any other American woman playwright. Her plays accurately reflected, better than those of any other dramatist during this period, the position of women in American society.

Miss Crothers chronicled, sometimes seriously, more often humorously, such timely problems as the double standard (*A Man's World*, 1910), trial marriage (*Young Wisdom*, 1914), flaming youth and the problem of the younger generation (*Nice People*, 1921; *Mary the Third*, 1923), Freudianism (*Expressing Willie*, 1924) and divorce (*Let Us Be Gay*, 1929; *As Husbands Go*, 1931; *When Ladies Meet*, 1932). These and other successes, such as *Old Lady 31* (1916), *A Little Journey* (1918) and *39 East* (1919), were marked by simplicity of plot, the happy ending and expert dialogue, which shrewdly combined instruction and amusement, sentimentality and humour, tears and laughter. Her comedies always advocated the classic ideals—sanity, moderation and the balanced view of life. Most of the plays were published.

Miss Crothers took full responsibility for the entire production of almost all her plays, casting and directing such stars as Carlotta Nillson, Maxine Elliott, Emma Dunn, Francine Larrimore, Christal Herne, Lily Cahill, Frieda Inescourt, Tallulah Bankhead, Katharine Cornell and Gertrude Lawrence. Never an ivory tower dramatist, during World War I she was founder and president of Stage Women's War Relief; during the depression of the 1930s she was founder and president of the Stage Relief fund, which aided needy theatre folk; and during World War II she helped organize and directed the American Theatre Wing, famous for the Stage Door Canteens.

The best and most instructive statement of her dramatic theory is to be found in her essay, "The Construction of a Play," collected in *The Art of Playwriting* (1928). (I. An.)

**CROTONA** (CROTO or CROTON; mod. CROTONE), a Greek town in southern Italy on the east coast of the territory of the Bruttii (mod. Calabria), 7 mi. N.W. of the Lacinian promontory (Capo Colonne). It was founded by Achaeans led by Myscellus c. 710 B.C. Like Sybaris (*q.v.*), it soon became a city of power and wealth. It was especially celebrated for its successes in the Olympic games from 588 B.C. onward, Milo (*q.v.*) being the most famous of its athletes. The philosopher Pythagoras established himself there c. 530 B.C. and formed a society of 300 disciples sympathetic toward aristocracies. In 510 B.C. Crotona was strong enough for its people to defeat the Sybarites and raze their city to the ground. At this time many smaller cities were allied to Crotona. Shortly after the sack of Sybaris the disciples of Pythagoras were driven out and a democracy was established. In the 4th and 3rd centuries it suffered from the attacks of Dionysius I

of Syracuse, who became its master for 12 years, of the Bruttii and of Agathocles of Syracuse, and even more from the two invasions of Pyrrhus, king of Epirus, in 280–278 and 275, between which in 277 the Romans obtained possession of it. Livy states that the walls had a length of 12 mi. but that after the wars with Pyrrhus about half the area between them had ceased to be inhabited.

During the Second Punic War, Crotona revolted from Rome after the battle of Cannae in 216 B.C.

The importance of the city was mainly due to its harbour, which, though not a good one, was the only port between Tarentum (Taranto) and Rhegium (Reggio). The original settlement occupied the hill above it (143 ft.) and later became the acropolis. Its healthy situation was famous in antiquity, and to this was ascribed its superiority in athletics; it was the seat also of a famous medical school mentioned by Herodotus. On the Lacinian promontory was the famous temple of Hera Lacinia of which only one column is standing. It was approached by a processional way from Crotona, which, in front of the gate into the enclosure wall, was about 20 yd. wide. The full uncovering of the sanctuary was begun about 1955.

The ancient site was occupied by the medieval Cotrone. There ensued a long period of obscurity, terminated about 1921 by a commercial and industrial revival; the ancient name, in Italian *Crotone*, was resumed in 1928. The population of the commune was 42,393 in 1961.

**CROTON OIL** (OLEUM TIGLI), an oil prepared from the seeds of *Croton tiglium* (family Euphorbiaceae), a tree native or cultivated in India and the Indonesian archipelago. Its use as a drug apparently originated in China; it was unknown to the ancient Hindus. In the 16th century the Dutch introduced it into Europe, where it had alternate periods of favour and disfavour as a medicinal agent.

The seeds resemble those of the castor-oil plant but do not have a polished or mottled appearance. The kernels contain from 50% to 60% of oil, which is obtained by bruising them to a pulp and expressing between hot plates. The oil is a brownish or pale yellow transparent and viscous liquid with an acrid persistent taste and a disagreeable odour. The active component of the oil is not known with certainty but appears to be associated with a solid fraction known as croton resin.

Applied to the skin, croton oil acts as a powerful irritant, inducing so much inflammation that definite pustules are formed. Taken internally, even in minute doses, it soon causes colic and a fluid diarrhoea; larger doses produce severe inflammation of stomach and bowels. These effects may follow absorption of the oil by the skin. Croton oil was formerly employed as a purgative or as a counter-irritant, but it is now considered too dangerous for medicinal use. It is sometimes used in veterinary medicine as a purgative.

(V. E.)

**CROTUS RUBIANUS** (JOHANNES JÄGER) (c. 1480–c. 1539), German humanist, was born at Dornheim and educated at Erfurt, later becoming professor of theology at Cologne. In 1515 he contributed to the collection *Epistolae Obscurorum Virorum*, his satirical letters on scholasticism and monasticism. After four years in Italy, he became rector of Erfurt university (1520) and there entertained Martin Luther. Three years later he went to Fulda, but finally settled in Halle, where he reverted to his old religion (c. 1530) and became a canon. His *Apologia* appeared at Leipzig 1531.

**CROUP** is an acute affliction of children characterized by harsh cough, hoarseness and laboured breathing. These symptoms result from inflammation of the membranes of the larynx and spasm of the laryngeal muscles. Allergy or physical irritation (such as cold air) occasionally cause this reaction, but it is usually caused by infection of the area. Croup occurs most commonly during early childhood because of the greater susceptibility of young children to respiratory infections and because of the size and structure of the larynx at that time of life.

In treatment, steam inhalations may afford considerable relief. The effectiveness of antibiotics depends upon the sensitivity of the microorganism causing the particular infection. (M. O. B.)

**CROUSAZ, JEAN PIERRE DE** (1663–1750), Swiss theologian, philosopher and controversialist whose letters to a wide range of correspondents reveal the intellectual climate of his time. Born at Lausanne, April 13, 1663, he was professor there from 1700 to 1724 (being twice rector of the university), and again from 1738 to 1749. In the interval, having left Switzerland as a result of theological disagreement, he held a chair at Groningen for two years, and from 1726 to 1732 was tutor to Prince Frederick of Hesse-Cassel. He died in Lausanne, Feb. 22, 1750. Crousaz published numerous mathematical and philosophical works. His *Traité du beau* (1714) was an attempt to explain subjective differences in aesthetic outlooks. With the encouragement of Cardinal Fleury, he sought to refute the doctrines both of Pierre Bayle and of Leibniz. His critique of Pope's *Essay on Man* was translated into English by Samuel Johnson (1742). His greatest importance lies in his correspondence, which was still unpublished in the early 1960s, although about 2,000 letters had been located. It brought him into touch with many leading figures in intellectual life: Ferchault de Réaumur, Antonio Conti, Fontenelle, Noel Antoine Pluche, Dortous de Mairan, Jean Bernoulli, Jean Paul Bignon, Jean Alphonse Turretini, Jean Barbeyrac, Pierre Des Maizeaux, Louis Racine, J. B. Rousseau, Voltaire, Henri Francois D'Aguesseau and William Wake, archbishop of Canterbury.

See J. de la Harpe, *Jean-Pierre de Crousaz* (1955). (Rt. S.)

**CROW**, a Siouan-speaking Plains Indian tribe known also as the Absaroka and linguistically and historically affiliated with the Hidatsa (q.v.) of the upper Missouri river. Probably lured by the trade in horses, the Crow broke with the Hidatsa and moved westward early in the 18th century. By 1740 the Crow had emerged as middlemen engaged in the trading of horses, bows, shirts and featherwork to the village Indians in return for guns and metal goods which they carried to the Shoshone in Idaho.

The Crow roamed the Yellowstone river and its tributaries, especially the Bighorn river, into Wyoming. They were divided into three bands known as the Mountain, River and Kicked-in-Their-Bellies. In 1868 they accepted reservation lands and in the early 1960s were situated on 2,282,764 ac. of former tribal lands in southeastern Montana. All but 14% of the reserve was owned by the Crow.

The majority of the Crow on the reserve had a sixth-grade education or more, and most of the families received an income of more than \$2,000 per year. In population the Crow, at one time, may have numbered between 4,000 and 5,000. During the 1960s the Crow in Montana were enumerated at 3,565.

Much of Crow life revolved around the buffalo and the horse. The former provided them with food, clothing, robes, tepee covers, sinew thread, containers and shields. The Crow used the "surround" method of hunting and killed buffalo with sinew-backed and compound elkhorn bows. The processing and preparation of food, housing and clothing were tasks for the women. The meat was dried and stored in rawhide envelopes (parfeches). Clothing of both sexes was tailored of deer, elk and buffalo hide. Men commonly wore the two-piece soled moccasin, breechclout, hip-length leggings, shirt and buffalo robe. The war bonnet of eagle feathers was worn on ceremonial occasions by renowned warriors. Women covered themselves with a long sleeveless skin dress and almost knee-length moccasins.

The Crow traced their descent matrilineally. They were organized into 13 exogamous sibs which in turn were united into six unnamed phratries. Each sib had an outstanding warrior who acted as its chief. The kinship system was of the "Crow" type (see KINSHIP TERMINOLOGY). Paternal relatives were treated with respect and were feasted, but especially strong avoidances, including a taboo on conversation, characterized the son-in-law and parent-in-law relationship. Brothers and sisters were taught, out of respect, to avoid speech and bodily contact. However, a man could be familiar with potential spouses and with the wives of his own and sib brothers. These, together with a man's "joking relatives," commonly ridiculed him for his social errors.

The quest for a supernatural guardian who adopted his "child" was basic to Crow religious belief and practice. Fasting in isolation, wailing, and tormenting of the body with skewers passed

through the chest and back tissues were usual practices to induce a vision. Mementos of this experience were gathered into a "medicine bundle." Among the Crow the most notable bundles were those associated with the sun dance, medicine arrows and tobacco. Tobacco, according to myth, was given to the Crow to overcome their enemies, and they cultivated it with ceremonial rite.

Warfare was largely a matter of raiding for horses, and victorious warriors were expected to dispose generously of their booty. The stylized coups which had to be completed before recognition as a chief reflect the psychology of the raid; as in (1) wresting a weapon from an enemy, (2) striking an enemy with a coupstick, (3) taking a horse tethered within the enemy camp and (4) leading a war party without loss of life. The bow and arrow, lance, shield and medicine bundle constituted the usual armament of the Crow warrior.

The recitation of war exploits was introduced into every religious and social occasion, and the sun dance (q.v.), the most important rite, was performed to attain vengeance. See also PLAINS INDIANS.

**BIBLIOGRAPHY.**—R. H. Lowie, *Religion of the Crow Indians* (1922) and *The Crow Indians* (1935, 1956); F. B. Linderman, *Plenty-Coups, Chief of the Crows* (1963). (F. W. V.)

**CROW**, a common name for several species of *Corvus*, family Corvidae, the largest of the perching birds. In the U.S. the common crow is *Corvus brachyrhynchos*, a deep-glossy-black bird from 17 to 21 in. long, with black bill and feet. The crows of England and the continent are the all-black carrion crow (*C. corone*) and the grayish-bodied hooded crow (*C. cornix*); both are large, chunky birds averaging 18 in. in length.

Although the American common crow feeds largely on grain (a habit that makes it very unpopular with farmers), it also destroys quantities of harmful insects. In the central portions of Canada and the northern U.S., the crow is very destructive to nesting waterfowl as it is much addicted to eating their eggs. It is gregarious and at times forms large roosts, but does not nest in colonies. Each mating pair has its own nest of sticks and twigs, usually high up in a tree, in which are laid five to six, sometimes eight, greenish to olive eggs with darker speckles. Four races, or varieties, are recognized.

The carrion crow is resident in Britain and in much of southwestern Europe. It shares its range with the hooded crow. Both forms migrate south in winter, a line from the Firth of Clyde to the head of the Adriatic roughly dividing their summer homes; the carrion crow occurs to the southwest of this line, the hooded crow to the northeast. Where the ranges overlap, the two species appear to interbreed freely, sometimes producing intermediate types. The European crows feed on carrion, small birds, eggs, etc.; they build isolated nests and reproduce much the same as the American species.

Several other species of *Corvus* are common: the American northwestern crow (*C. caurinus*) occurs from Kodiak Island to Puget sound; the fish crow (*C. ossifragus*), along the Atlantic coast of North America; and the house crow of India (*C. splendens*), which is very tame and useful as a scavenger. The so-called carrion crow of the U.S. is the black vulture (see VULTURE). (Ht. Fn.)

**CROWBERRY** (CRAKEBERRY), a common name for a low-growing heathlike shrub (*Empetrum nigrum*) belonging to the family Empetraceae (q.v.), found in alpine situations throughout the northern hemisphere and also in the Andes. It has slender, wiry, spreading branches covered with short, narrow, stiff leaves, the margins of which are recurved to form a hollow cylinder con-

JOHN H. GERARD  
COMMON CROW (*CORVUS BRACHYRHYNCHOS*)

cealing the hairy under surface. The minute flowers are succeeded by black, edible berrylike fruits, one-fourth to one-third inch in diameter, which are much eaten by birds. Crowberry finds limited use as an ornamental in the cool rock garden.

**CROWDER, ENOCH HERBERT** (1859–1932), U.S. army officer who administered the Selective Service act during World War I and later served as ambassador to Cuba. He was born in Edinburg, Mo., on April 11, 1859, and attended local public schools. He graduated from the U.S. military academy at West Point in 1881. After four years of Indian warfare (1881–85) in the cavalry, he was detailed as professor of military science at the University of Missouri, where he studied law and received a law degree. In 1891 he entered the judge advocate general's corps. During the Spanish-American War he was judge advocate of troops in the Philippines, where he served also as associate justice of the supreme court (1899–1901). He headed the first division (administrative affairs) of the U.S. army general staff in 1903 and was military observer with the Japanese army during the Russo-Japanese War (1904–05). He then went to Cuba (1906–08) as secretary of state and justice and devised Cuba's first electoral laws. After attending the fourth Pan-American congress in Argentina, he became judge advocate general of the U.S. army in 1911.

When the U.S. entered World War I in 1917, Crowder's office drafted the Selective Service act (see CONSCRIPTION). At first Crowder doubted its practicality, but when the law was enacted in May 1917 he was appointed to administer it as provost marshal general. During earlier wars, dependence on state militia and volunteer regiments had greatly confused military mobilization. The draft was democratic in spirit and practice, and its administration was decentralized to local communities. Crowder presided over the registration of some 24,000,000 men and an increase in the armed forces from about 213,000 to more than 3,600,000 men, of whom 2,800,000 were inducted through selective service. This experience provided valuable precedents for World War II when selective service was re-instituted. Crowder described his contributions in *The Spirit of Selective Service* (1920).

After the war Crowder helped revise Cuba's electoral laws and served there as personal representative of President Wilson and President Harding until March 5, 1923, when he was named U.S. ambassador to Cuba. He retired on Sept. 1, 1927, upon completing 50 years of government service. He died in Washington, D.C., on May 7, 1932.

See David A. Lockmiller, *Enoch H. Crowder: Soldier, Lawyer and Statesman* (1955). (D. F. Tr.)

**CROWE, SIR EYRE** (1864–1925), British diplomat who was a vigilant critic of German foreign policy in the years preceding World War I, was born at Leipzig on July 30, 1864, the third son of Sir Joseph Crowe, the art historian, and of Asta von Barby. He was educated in Germany and France and when he entered the British foreign service in 1885 could claim to be trilingual. His subsequent career was spent almost entirely at Whitehall and he never held a diplomatic post abroad, his ambition being to become head of the foreign office. Crowe was a prodigious worker and mastered the history and principles of British foreign policy with great thoroughness. In 1903 he married one of his German cousins, Clema Gerhardt, widow of Eberhardt von Bonin.

Crowe took an important part in reorganizing the foreign office in 1904 and 1905. In Jan. 1907 he wrote the memorandum, with which his name is historically associated, "on the present state of British relations with France and Germany." It had great influence on the foreign secretary, Sir Edward Grey. Crowe warned him that Germany aimed at the domination of Europe, that concessions would only feed its appetite and that the entente with France must not be abandoned. Crowe, who was knighted in 1911, became assistant undersecretary of state for foreign affairs in 1912. In 1914 he strongly pressed the case for British intervention against Germany and in 1919 he was one of the British plenipotentiaries at Versailles. He became permanent undersecretary at the foreign office in 1920. His health, which had never been good, broke down under the self-imposed strain of ceaseless work and he died at Swanage, Dorset, on April 28, 1925.

Crowe's great services were fully recognized by successive prime

ministers and foreign secretaries, and the verdict of Stanley Baldwin—"We have lost the ablest servant of the crown"—was one that few would have cared to challenge. (R. N. W. B.)

**CROWE, SIR JOSEPH ARCHER** (1825–1896), English art historian who is best known for his collaboration with G. B. Cavalcaselle (*q.v.*), was also a foreign service official and journalist. He was born in London, Oct. 20, 1825, and passed his boyhood mainly in Paris, where his father, Eyre Evans Crowe, was *Morning Chronicle* (London) correspondent. After 1843 he became correspondent in London to his father's paper and correspondent and foreign editor to the *Daily News* (London). He represented the *Illustrated London News* during the Crimean War and the *Times* (London) during the Indian mutiny. His work impressed the foreign secretary, Lord John Russell, who appointed him consul general at Leipzig in 1860. He thereafter held various diplomatic posts in Europe. In 1890 he was appointed knight commander of St. Michael and St. George. He died at Gamburg-on-the-Tauber, Bavaria, Sept. 6, 1896.

In 1847 Crowe had encountered Cavalcaselle. The two joined forces to produce *The Early Flemish Painters* (1856), which Crowe had already begun; *A New History of Painting in Italy, From the Second to the Sixteenth Century* (3 vol., 1864–68); *A History of Painting in North Italy* (2 vol., 1871); and other works. The two Italian histories were revolutionary in English art literature in the way in which they combined stylistic and documentary evidence; and they remained in the mid-20th century the standard general histories of Italian art in English.

In addition to those works already mentioned Crowe also wrote *Reminiscences of Thirty-Five Years of My Life . . .* (1895) and, with G. B. Cavalcaselle, *A History of Painting in Italy . . .* (ed. by L. Douglas) (1903), the preface of which contains an excellent biographical sketch. (P. J. My.)

**CROWFOOT**, the name applied to several species of *Ranunculus*, most of which are better known as buttercups. They usually have leaves divided into five to seven sections, bearing some resemblance to birds' feet, hence Crowfoot. See also RANUNCULACEAE; RANUNCULUS.

**CROWLAND** (CROYLAND), a civil parish in the Parts of Holland, Lincolnshire, Eng., lying in a low but fertile fen district near the Welland river, 9 mi. N.N.E. of Peterborough by road. Pop. (1961) 2,879. The origin of the monastery which existed in the Anglo-Saxon period is somewhat obscure. The documents in the *Historia Crowlandensis*, supposedly by Abbot Ingulf, are forgeries of about 1182–1450. Matthew Paris, using the chronicle of the monk Felix (*c.* 751), describes the coming of the hermit St. Guthlac to Croyland, then an island, on St. Bartholomew's day 699. Guthlac died in 714. The first abbey (716–860), built by King Aethelbald over Guthlac's cell, was destroyed by the Danes and rebuilt in stone, 948–975. Crowland abbey was in possession of most of its lands before the compiling of Domesday Book. Of Abbot Joffrid's church of 1100–70 parts survive. There was later damage by fire and earthquake, but then came a great period (1392–1469) under Abbots Overton, Upton and Lytlington, who transformed the building into the Perpendicular style. The north aisle of the abbey has been restored and is used as the parish church; the remainder forms a striking ruin. The church has a 15th-century carved wooden screen and a Norman immersion font. The west front of the abbey nave, dating to the great period, retains many canopied statues of patrons spiritual and temporal and the tympanum over the doorway contains scenes from the life of St. Guthlac. Oliver Cromwell besieged it in 1643, and the 18th and 19th centuries saw the south aisle and wall of the nave reduced to ruins. The triangular footbridge in the market place once spanned three streams which are now covered over; it is a 14th-century structure which replaced an earlier one. Crowland's annual St. Bartholomew fair, first mentioned in a charter of Henry III (1226), is still held early in September. The spelling Crowland appears only after the Dissolution.

**BIBLIOGRAPHY.**—R. Gough, *The History and Antiquities of Croyland Abbey*, 3 vol. (1780); F. M. Page, *The Estates of Crowland Abbey* (1933); *Victory County History of Lincolnshire*, vol. ii (1906).

(G. W. By.)

**CROWLEY, ROBERT** (c. 1518–1588), English Puritan and social reformer, who played a prominent part in the vestiarian disputes of Elizabeth I's reign, was educated at Magdalen college, Oxford, of which he became a fellow. He set up a printing office in Holborn, London, and from there published many of his own tracts. Typographically his most notable production was an edition of *Pierce Plowman* in 1550. His *An informacion and Peticion agaynst the oppressours of the pore Commons of this Realme* (1548) is remarkable for its attack on the "more than Turkish tyranny" of the landlords and capitalists of that day. A Christian socialist, Crowley approved the efforts of the protector Somerset to stop enclosures.

In the most important of his writings, the *Way to Wealth* (1550), he attributes the failure of the protector's policy to the organized resistance of the wealthier classes. Three works written in verse were the *Voyce of the laste trumpet* (1550), *One and thyrtye Epigrammes* (1550) and *Pleasure and Payne* (1551). Crowley gave up printing when he was ordained in 1551. During Mary's reign he was in exile at Frankfurt. On Elizabeth I's accession he became archdeacon of Hereford in 1559 and prebendary of St. Paul's in 1563. He was incumbent of St. Peter le Poer in London, and then of St. Giles, Cripplegate. His objection to surplices, which he called "porters' coats," led in 1566 to his deprivation and imprisonment, when he refused to allow his choir to wear them. In the same year he published a tract entitled *A briefe discourse against the outwarde apparell and Ministring garments of the popishe church*. In 1576 he accepted the living of St. Lawrence Jewry, but resigned two years later. He died on June 18, 1588.

See J. W. Allen, *History of Political Thought in the Sixteenth Century* (1928); A. Peel, "Robert Crowley: Puritan, Printer, Poet," in *Journal of the Presbyterian Historical Society of England* (May 1938). (G. Hv.)

**CROWN AND REGALIA.** Regalia, or crown jewels, are the visible emblems or insignia of royalty that pertain to a monarch. They vary greatly in different countries, both in significance and value, but in European countries a crown, generally richly jeweled, is the chief insigne.

**Crowns.**—The crown (Lat. *corona*) or diadem and coronet (O.F. *coronete*, diminutive of *corone*, "crown") are ornaments, worn on or round the head, which have been used in nearly all civilizations and epochs. In ancient times wreaths of the most varied kinds were in use, made from flowers, ivy, rushes, vine leaves, etc., or from durable materials. They were used in family life, at symposia, in weddings and in the cult of the dead, but were also officially conferred. The Roman emperors wore golden imitations of the victor's laurel wreath, and after the emperor cult had made them the sun god's earthly image they were depicted with the aureole. The highest sign of imperial dignity, the diadem, Hellenistic in origin and a symbol of monarchy, consisted of a band of material with a precious stone fastened to it above the brow. Caesar rejected the diadem and wore the golden wreath of the Etruscan kings. Succeeding generations accepted the monarchy and with it the diadem, and its band was studded with precious stones and edged with pearls so that it became a fixed circlet. In addition the emperor of later times as commander of the army wore a helmet more splendid than that of his officers, made of gold and set with gems.

In the Byzantine era diadem and helmet were united in a golden crown, half spherical in form, set with pearls and precious stones, called *kamelaukion* because of its likeness to the priest's head-dress of that name. The Norman rulers of south Italy and Sicily took over this type of crown when they were raised to the rank of king (1130). The emperor Frederick II (d. 1250) followed their example. In his wife's grave was found a crown (preserved at Palermo) that must have been made for the last of the Hohenstaufen emperors; it shows the

*pendilia*, of golden wire and precious stones, which hung down on both sides and which derive from the ribbons that once floated from the diadem band.

Crowns played a great part in the church from ancient times; the martyrs were represented with the "crown of eternal life," and churches, especially altars, were embellished with votive crowns suspended on chains. From the 11th century, Christ and the Virgin were depicted with royal crowns, while in the late middle ages God the Father was represented with an emperor's crown.

Germanic tradition also affected medieval crowns. In the time of the migrations tribal kings were distinguished from the warriors by their long, flowing hair or by their splendid helmets, sometimes gilded. However, it is recorded that Clovis, king of the Franks (d. 511), wore a crown as a symbol of *regnum*, "royal authority." The oldest extant crown is that belonging to Theodelinda, queen of the Lombards (d. 627), in the cathedral treasury in Monza (q.v.); it is a simple circle set with 180 stones in five rows. West Gothic sacred crowns with small chains that were discovered in the 19th century near Fuente de Guarrazar, in Spain, also date from the 7th century; although they served as church ornaments they must have resembled the crowns worn at the time. The hooped crown, with two hoops crossing over the crown, can be traced to 850 and may perhaps have been worn by Charlemagne; technically it is a simplified helmet with the intermediary plates omitted, and was occasioned by the Carolingian attempt not to fall behind the Byzantine emperors with their *kamelaukion*. However, simple circlets were also worn in the 9th century, as is shown by the "iron crown" in Monza, which probably comes from the legacy of a Carolingian princess. At this time it became usual, following Old Testament tradition, to give the ornaments that surmounted the circlet the form of lilies. The oldest extant lily crown rests on the head of the Madonna of Essen (c. 980). There is perhaps an example of a narrowed-down Carolingian hooped crown with lilies in the one worn by the golden statue of St. Foy in Conques (near Rodez, in Aveyron département).

The most magnificent medieval crown is that made c. 960 for the Holy Roman emperor Otto the Great, which has been known as the *Reichskrone* ("crown imperial") at least since the 12th century and is the most treasured piece of the secular treasury in Vienna. It consists of eight plates, four of them adorned with enamels, the details being derived from Byzantine art. In the setting of the stones the proportions of the numbers were taken into account, but numbers with biblical significance took the place of those beloved by the Germans. In addition the various kinds of precious stones enumerated in Rev. xxi, 19–20 were used. The hidden meaning of the crown (on the analogy of the allegorical interpretation usual at the time) can be interpreted thus: the left side with the enameled pictures of David and Solomon refers to the kingly office, the right side to the priestly office; the part above the brow with the 12 different gems refers to the New Testament (i.e., the 12 apostles), while the similarly decorated part above the neck refers to the Old Testament (i.e., the 12 tribes). It is noticeable that this crown possesses only a single, vertical hoop; the reason for this is that, as the high priest had worn *corona aurea super mitram*, so the emperor wore a mitre beneath the crown. In the time of the Holy Roman emperor Conrad II (d. 1039) the original hoop was replaced by a new one and the cross, originally worn on the breast, was fastened to the crown above the brow. The pendants and ornaments which originally belonged to the sides have been lost. According to its de-

FIG. 3.—RECONSTRUCTION OF THE CROWN IMPERIAL, WITH MITRE

late middle ages. The shape of this crown is the basis of the Russian crown.

The English and French medieval crowns have perished. The medieval kings attached importance to the possession of more than one crown and Edward II of England had at least ten. In times of need some would be pawned or sold, and when the fashion changed old crowns would be remodeled. In the late middle ages there was a saying—though it was disputed—that the hoops on the crown were the prerogative of the emperor, and since the king of England did not want to seem inferior to the emperor, Henry VII's crown exhibits a double hoop. This made the kings of France and Scotland do the same in order to show their equality, and thus the hooped crown became the typical king's crown. Hence the circlet or coronet could become the symbol of nobility, and as early as the 9th century a *corona ducalis* ("ducal crown") was mentioned. But even in the 12th century a pointed cap was the sign of aristocracy, and the German electoral princes always contented themselves with a fur-edged hat.

From the 13th century artistically worked wreaths included the golden coronet decorated with precious stones (*circulum, garlanda*) which was set on the head of a bride, and with which princesses adorned themselves. From the 14th century princes and counts and finally barons wore such coronets, and from the end of the 15th century even the lower nobility took over his right. In England there was a peculiar development: the nobility were not content with adorning their coats of arms with such coronets but actually wore them at coronations, which they continue to do. Gradually, in England as in the rest of Europe, the splendour and number of points were fixed for the crowns of each rank of the nobility. The triple crown of the pope has a unique history. (See VESTMENTS, ECCLESIASTICAL.)

**Other Regalia.**—*Sceptre.*—The primeval symbol of the staff was familiar to the Greeks and Romans and also to the Germanic tribes in various forms (*baculus*, "long staff"; *sceptrum*, "short staff") and had various significances. The staff of command belonged to God as well as to the earthly ruler; there was the old man's staff, the messenger's wand, the shepherd's crook and, derived from it, the bishop's; and so on. The Carolingians first used a long staff but also imitated the short Roman one. Consequently from the 10th century two staffs were used in the consecration of a king. In most countries the second was displaced by the orb (see below). The only country to retain two staffs was England, where the two became alike in length but were distinguished in being surmounted respectively by a cross and by a dove. The sceptre with the cross was interpreted as being the symbol of the ruler's might; the

sceptre with the dove was the symbol of the king's office as the head of justice and equity.

**Orb.**—The orb was also borrowed from the Romans. It was originally a representation of the *sphaera* ("cosmos"), conceived as a ball; the king of the gods, Jupiter, and hence the emperor, as his earthly representative, was depicted with it. Although this significance became outdated Christians were able to use the symbol by setting a cross above the ball. The Byzantines kept it in this form until the late middle ages, but only in visual representations of their emperor. The western emperors also had themselves depicted with a similar ball in the 9th and 10th centuries. The first actually to take an orb in his hand was Henry II at his coronation as emperor (1014). From that time the "imperial apple" belonged to the emperor's insignia, but as early as the 11th century other European rulers wanted to be painted with, and then to possess, an imperial apple as well. Only the king of France attached no importance to the emblem. On the English seal the dove of the Holy Ghost was also set upon the ball's cross. In the 14th century one of the sceptres and the orb were temporarily combined to form one symbol, but since the 16th century a separate orb has been a part of the English coronation. In every country the memory of the original significance has been revived from time to time, or the ball has been referred back to the earth or globe, but the essential motive in the preservation of the orb was that it belonged by general consent to a true king.

**Sword.**—The sword with which the kings were girded as knights must be reckoned among the regalia, for it was used for investiture or was carried in front of the ruler as a sign of his power. Many such swords survive. The oldest is the Essen sword (in Münster) which perhaps belonged to Otto II and which has a scabbard of pure gold (10th century). In the emperor's treasures in Vienna there are two 11th–12th-century swords of state. The "sword of Charlemagne" (Louvre) is in fact north European work and no older than the 12th century. In England there are five swords connected with the regalia. (See also SWORD: Presentation and State Swords.)

**Others.**—Other emblems of royalty belonging to the regalia are the ring, and in some countries the lance and a helmet with a crown reversed upon it. Charles I's ring, bequeathed to George III by Cardinal York, is in the Tower of London. The armillae (bracelets) of the medieval kings, which still retain their place in the English coronation ceremony, took their justification from the example of the Jewish kings but actually derive from the *baugae* ("bracelets") of the Germans.

**Existing Regalia.**—Since the gold of which they were made and the gems which adorned them were often needed for other purposes, many regalia have perished. The ancient regalia that exist are therefore very unequally distributed over Europe.

**France.**—The French insignia and coronation robes were kept in the Benedictine abbey of St. Denis, north of Paris. Nearly all of them were destroyed during the Revolution but they are known through inventories and old prints. What has been preserved is exhibited in the Galerie d'Apollon in the Louvre.

**Spain.**—Spain also has almost no royal emblems left. The crown discovered in Sancho IV's tomb at Toledo probably had belonged to King Alfonso VIII of Castile (1158–1214). A crown which Beatrice (d. 1235), the wife of Ferdinand III of Castile-León, brought with her from her German homeland was stolen in 1873, but a photograph of it exists. A conical crown, dating from King Martin I of Aragon, is preserved in Barcelona, and in Granada there is a circlet ornamented with garnets which tradition associates with Queen Isabella (d. 1504).

**Italy.**—In Monza the crown of Theodelinda, queen of the Lombards, and the Carolingian "iron crown" are preserved, and in Palermo is a closed crown which belonged to the emperor Frederick II (see above, Crowns).

FIG. 5.—PAPAL TIARA (WITHOUT THE INFULAE)

FIG. 4.—CORONETS OF DUKES, MARQUESSSES AND EARLS

**Hungary.**—The so-called Crown of St. Stephen, or Holy Crown, is basically a Byzantine circlet of 1074–77, which the Hungarians early in the 12th century converted into an emperor's crown by adding a superstructure (strips of an older relic). No part of it could have been worn as a crown by King Stephen I (d. 1038). Stephen's coronation mantle, cap and sword are, however, preserved; and the Hungarian sceptre (a crystal ball on a short stem) may be even older.

**Poland.**—Three crowns, Hohenstaufen in origin, which were used by the 14th-century Polish kings were preserved as ornament for a cross in Cracow (late 15th century) and for the Sigismund relic in Plock (1370). In addition the replica of the "holy spear," which Emperor Otto III gave to the Polish king Boleslaw I in 1000, is preserved in Cracow. All the other objects are from the 16th, 17th or 18th centuries.

**Russia.**—The oldest of the existing royal emblems is the Great Monomach cap, with which the emperors were crowned until the 18th century, and a cone of gold pieces (14th century) with a conical point and a fur edging (17th century). Similar in form are other caps for the other realms of the empire. The series of orbs begins with the "Monomach's apple," made in 1627. Catherine sought to have royal emblems that were similar in form to those of the west but she tried to surpass them in splendour. The treasures that survived the Revolution are exhibited in the Kremlin, Moscow.

**Sweden.**—Regalia, no longer used at the coronation, are shown at the opening of the *Riksdag*. The king's crown was made in 1561 for Eric XIV and the crown prince's coronet, which was placed over a great velvet hat, was made for Charles X Gustavus (1650). The series of orbs begins with one which Eric XIV commissioned.

**Denmark.**—The Danish regalia are exhibited in Rosenborg castle, Copenhagen, the chief being the crown made for Christian IV (1588–1648). At the coronations (up to 1848), however, the crown made about 1665–70 for Frederick III was used. The orb was also made for him.

**Germany.**—Germany is the richest of all countries in regalia. The most important royal emblems were preserved in the imperial castle of Trifels in the middle ages. In 1423 they were entrusted to the free imperial city of Nürnberg and in 1796 were safely carried to Vienna in face of the revolutionary arm (now Hofburg, secular treasury). The central feature of the crown jewels is the imperial crown made for Otto I. The "holy spear," acquired by Henry I, was the most important imperial relic. "Attila's sabre" is a Hungarian ceremonial weapon of about 900.

The imperial treasury acquired a great many robes from the treasury of the kings of Sicily on Henry VI's marriage to Constance in 1186. Some important regalia are preserved in the treasury of Aachen cathedral, others in the church at Bamberg which was endowed by Henry II. Some crowns went abroad, to Stockholm, Poland, etc. In addition there are the regalia which the German princes, striving toward royal dignity, had made: the Bavarian regalia are in the treasury in Munich, the Prussian in Hohenzollern castle, Sigmaringen.

**England.**—England's regalia were all sold during the Commonwealth, but the inventories which were made for the sale and earlier records give an idea of what once existed. After the Restoration new crown jewels were made and almost every succeeding generation has augmented them.

The king of England has three crowns. St. Edward's crown, made for the coronation of Charles II in 1661 after the pattern of the ancient King Edward the Confessor's crown destroyed by the Commonwealth, is used at the coronation ceremony. The imperial state crown, made for Queen Victoria in 1838, contains the Black Prince's ruby, which was worn by Henry V at the battle of Agincourt; the great sapphire from the crown of Charles II; Elizabeth I's pearl eardrops; the sapphire from the coronation ring of Edward the Confessor; and a 309-carat diamond, one of those cut from the Cullinan. The imperial crown of India owes its origin to a law that prevents the crown of England from being taken out of the country; when, therefore, George V was crowned in Delhi (1911) as emperor of India, a new crown had to be made.

Next in importance are the queen's crowns or diadems. The

crown of Queen Mary of Modena, wife of James II, is of the usual formal shape and contains no coloured stones. The crown made in 1937 for the coronation of Queen Elizabeth, consort of George VI, contains the Koh-i-Nor diamond, which was presented by the army of the Punjab to Queen Victoria.

The prince of Wales's crown is of gold without jewels and is distinguished from a coronet by one arch, introduced by Charles II.

The other regalia consist of the king's two sceptres (the royal sceptre adorned with the 516½-carat Star of Africa diamond cut from the Cullinan) and St. Edward's staff; the queen's two sceptres and ivory rod; the king's orb and the queen's orb; coronation bracelets, St. George's spurs, and the ampulla and anointing spoon. Besides the regalia proper there are many pieces of royal plate.

**Scotland.**—The "honours of Scotland," preserved in Edinburgh castle, were used for the last time in 1651. The hoops of the crown date from James IV (1488–1513) and the circlet itself (which replaced an older one) only from James V (1513–42). James V also had the sceptre lengthened; its shaft came to Scotland in 1492 as the gift of Pope Alexander VI. The sword was a gift of Pope Julius II in 1507.

**Ireland.**—The Irish crown jewels were stolen from Dublin castle and have never been recovered. There was nothing of historic or of great intrinsic value among them.

See also THRONE; ROBES; CORONATION.

**CROWNE, JOHN** (c. 1640–c. 1703), English dramatist popular at courts of Charles II and James II, was born about 1640 in Nova Scotia. His father had emigrated there but was possessed by the French government. John Crowne arrived in England soon after the Restoration, and his first literary work was a romance *Pandion and Amphigenia* (1665). The earl of Rochester gained him the commission for a masque for performance at court *Calisto* (1675), and this brought him into favour with Charles II. *The Country Wit* (1675), based on Molière's *Le Sicilien* and also admired by the king, was followed by many other plays: comedies, heroic dramas and historical tragedies all dedicated to prominent figures at court and acted with great success. *City Politiques* (1683), which satirized the Whig party and contained characters readily recognizable as portraits of Titus Oates and others, was one of his best comedies but made him many enemies. Crowne petitioned the king for a small place that would release him from the necessity of playwrighting, and Charles agreed to grant this request on condition that Crowne would write one further play, and suggested he base it on Mureto y Cavaña's *No puede ser guardar una mujer*. The result was the lively *Sir Courtly Nice* (1685), which remained a stock piece for nearly a century. Of his other plays the most notable is *The English Friar* (1690), which owed a debt to Molière's *Tartuffe* and satirized the Catholic priests who had been powerful at the court of James II. Although his plays enjoyed great popularity, partly because of their topical wit, they lack literary distinction, and it is only for his creation of the "type" character of Sir Courtly Nice that Crowne is remembered. D. E. Baker in his *Companion to the Playhouse* (1764) states that Crowne was alive in 1703; but nothing is known of his later life.

The *Dramatic Works of John Crowne* were edited by J. Maidment and W. H. Logan in four volumes (1873–77).

See A. F. White, *John Crowne: His Life and Dramatic Works* (1922); G. P. Winship, *A Bibliography of . . . John Crowne* (1922).

**CROWN LAND**, in Great Britain, land belonging to the crown, the hereditary revenues of which were surrendered to parliament in the reign of George III.

In Anglo-Saxon times the property of the king consisted of (1) his private estate, (2) the demesne of the crown, comprising palaces, etc., and (3) rights in the folkland of the kingdom. By the time of the Norman conquest the three became merged into the estate of the crown, that is, land annexed to the crown, held by the king as king. He also ceased to hold as a private owner, but had full power of disposal by grant of the crown lands, which were increased from time to time by confiscation, escheat, forfeiture, etc. The history of the crown lands of the reign of William III was one of continuous alienation to favourites. Their wholesale distribution by William III necessitated the intervention of parliament, and in the reign of Queen Anne an act was passed precluding the alienation of crown lands. The income from certain crown lands was also made to constitute part of the civil list funds. At the beginning of his reign, George III surrendered to parliament the hereditary revenues of the crown, including the income from the crown lands, in return for a fixed "civil list" (q.v.), and the sovereign was also relieved by parliament of the cost of government and of the armed forces, etc. This course has been followed by all succeeding sovereigns. It is the income only which is surrendered to parliament, the ownership of the crown lands remaining vested in the sovereign. The control and management of the crown lands is regulated by the Crown Lands act, 1829, and various amending acts. Under the acts management is entrusted to the commissioners of crown lands (formerly the commissioners of woods, forests and land revenues) who have certain statutory powers as to leasing, selling, exchanging, etc.

**CROWN POINT**, a town of Essex county, N.Y., U.S., about 90 mi. N.E. of Albany and about 9 mi. N. of Ticonderoga, on the west shore of Lake Champlain. Putnam's creek, named for Israel Putnam of Revolutionary War fame, flows through the town. In 1609 Samuel de Champlain fought the Iroquois Indians there and began the enmity between the Five (later Six) Nations and the French. Subsequently Dutch and English traders traveled in the vicinity. In 1731 the French constructed a stone fort on the peninsula which they called *Point à la Couronne* ("Crown Point"). The fort was named Ft. St. Frédéric in honour of Jean Frédéric Maurepas. Despite English and colonial expeditions sent against it, Crown Point remained in French hands until 1759 when it was occupied by Lord Jeffrey Amherst who began construction near old Ft. Frédéric of a larger fort which was garrisoned but never completed.

At the outbreak of the American Revolution the fort was captured by Col. Seth Warner and a force of Green Mountain Boys; it remained in American hands except for a brief period in 1777 when it was occupied by a detachment of Burgoyne's invading army.

The permanent population of about 1,700 is swelled by summer residents and tourists. The chief occupation is farming; manufactures include lumber and woodenware. (G. L. F.)

**CROWN VETCH** (*Coronilla varia*), a spreading, long-lived, drought-tolerant legume, with attractive pinkish-white flowers, used principally for erosion control, as a cover crop and for soil improvement. Its perennial habit, associated with its habit of producing a dense surface cover and a deep, heavy root system on poor soils, makes it especially valuable for use on raw steep slopes along highways and similar places. It may be established either from seeds or from crowns. It has a broad adaptation to soils and climate. (F. V. G.; J. M. BL.)

**CROWTHER, SAMUEL ADJAI** (1809?–1891), African missionary bishop, was born in Oshogbo in the Yoruba country, West Africa, and was sold into slavery in 1821. The next year he was rescued, with many other captives, by H.M. ship "Myrmidon" and was landed at Sierra Leone. Educated there in a missionary school, he became a teacher and afterward missionary on the Niger. In 1842 he entered the Church Missionary college in London, and in June 1843 was ordained.

Returning to Africa, he worked among his own people and afterward at Abeokuta. There he devoted himself to the preparation of schoolbooks, and the translation of the Bible and Prayerbook into Yoruba and other dialects. In 1864 he was consecrated first bishop of the Niger territories. Crowther died in Lagos on Dec. 31, 1891.

See J. McKay, *The Life of Bishop Crowther* (1932).

**CROYDON**, one of the 32 London boroughs that comprise Greater London, Eng., forms part of its southern perimeter, bounded north by Lambeth, west by Merton and Sutton, east by Bromley, and south by Surrey County. It was established under the London Government Act 1963 (see LONDON) as an outer London borough on April 1, 1965, by the amalgamation of the former county borough of Croydon and the urban district of Coulsdon and Purley. It includes Addington, Addiscombe, Kenley, Norbury, Sanderstead, Selsdon, Shirley, South and Upper Norwood, Thornton Heath, and Waddon. Area 37.2 sq.mi. (96 sq.km.). Pop. (1961) 327,427. Its parliamentary constituencies are Croydon North East, North West, and South, and East Surrey (part). There are nearly 4,000 ac. of parks and public woodland.

Central Croydon was being extensively redeveloped in the 1960s. Notable new buildings include the Fairfield Halls, comprising a concert hall, a theatre, and an art gallery. The parish church of St. John the Baptist (founded c. 10th century) was burned in 1867 but restored by Sir George Gilbert Scott. Six archbishops of Canterbury are buried there, including John Whitgift (q.v.), who founded the school and almshouses (1596–99) that bear his name. Other notable churches include St. Michael and All Angels (1871) in Gothic style, around which early development of the Oxford Movement in Croydon was centred. Croydon is a bishopric suffragan in the diocese of Canterbury.

Educational facilities include two schools of the Whitgift foundation, a modern technical college and college of art, and an outstanding public library. Though largely residential, Croydon has factories and workshops, whose products include scientific instruments, internal combustion engines, and electronic equipment.

Croydon was originally farther west than its present location and is mentioned in 9th-century charters and in the Domesday Book. Earlier settlement is indicated by prehistoric remains near Addington Park, Mesolithic finds in Sanderstead and district, and Bronze Age remains at Purley and Coulsdon. On Farthing Down, near the Brighton Road in southern Croydon, are outlines of Celtic fields and a series of Saxon burials. All Saints' Church at Sanderstead has medieval wall paintings. There are several springs in the neighbourhood, which were important determinants of settlement in the chalk country.

The Manor of Croydon was presented by William I to Archbishop Lanfranc, founder of the archiepiscopal palace (now part of a girls' school) which from 1086 to 1758 was a summer residence of the archbishops of Canterbury. Its main buildings date from the late 14th and 15th centuries. From 1808 to 1896 the archbishops resided at Addington Palace, now the Royal School of Church Music.

The Surrey Iron Railway (1801), the first public goods railway in the world, ran between Croydon and Wandsworth. Croydon Airport, important in the history of British civil aviation, lies largely in Sutton. It was established in 1915 and made a government civil customs airfield in 1926; but after World War II its primacy passed to London Airport at Heathrow, and it was closed in 1959. (J. M. Bs.)

**CROZIER, WILLIAM** (1855–1942). U.S. army officer and inventor, was born at Carrollton, O., Feb. 19, 1855. He graduated from West Point in 1876 and served on the western frontier for three years thereafter against the Sioux and Bannock Indians. In 1888 he was sent by the war department to study artillery in Europe, and upon his return he was placed in full charge of the construction of gun carriages for the army. With Gen. Adelbert R. Buffington (1837–1922), the chief of ordnance, he invented the Buffington-Crozier disappearing gun carriage (1896). He also invented a wire-wound gun and perfected many appliances connected with heavy and field ordnance. During the Spanish-American War he was inspector-general for the Atlantic and Gulf coast

defenses. In 1899 he was one of the American delegates to the Hague Peace conference. He later served in the Philippines and in 1901 became chief of the ordnance of the U.S. army, a post he held until 1917. During 1912–13 he was also president of the army war college. As a member of the war council he was in France and Italy during the first half of 1918. His *Notes on the Construction of Ordnance* was adopted as a textbook in the schools for officers. He died Nov. 10, 1942.

**CRUCÉ, ÉMERIC** (c. 1590–1648), French monk, teacher and writer, was a pioneer advocate of international arbitration. His principal work, *Le nouveau cynée* ("The New Cyneas"; 1623), advocated arbitration of disputes and an assembly of princes or their permanent delegates, sitting in Venice, to deal with international problems. Republics were to arbitrate if princes became deadlocked; the papacy and France were given pre-eminent positions in the organization. Moral pressure would suffice for enforcement, though sanctions might be necessary.

Crucé was preoccupied by such problems as free trade and communications, agriculture, weights and measures, and canals, also problems of taxation, luxury and population. He paid little attention to the Thirty Years' War (1618–48), but was inevitably influenced by it. A true humanitarian and cosmopolitan, he placed merchant above soldier, and opposed national, racial and religious differences. Interested in the problem of Turks and Jews, he urged inclusion of Asia and Africa in a world organization.

**BIBLIOGRAPHY.**—Thomas Willing Balch, *The New Cyneas of Émeric Crucé* (1909); Jacob ter Meulen, *Der Gedanke der Internationalen Organisation, 1300–1800*, (1917); Charles Sumner, *Orations and Speeches*, 2:62 (1850). (P. B. P.)

**CRUCIBLE STEEL.** The crucible process was invented by British steel man and inventor Benjamin Huntsman about 1740. He took small pieces of carbon steel made by the old cementation (*q.v.*) process and charged them into fire clay crucibles which held about 100 lb. of metal. By heating these in a coke fire surrounding the crucibles he was able to melt the metal and obtain a homogeneous melt of uniform composition which he used to make into watch and clock springs. This was the first time that man was able to reach a temperature (2,900° F.) that would melt steel.

After about 1870 the Siemens gas-fired regenerative furnace replaced the old single coke-fire furnaces. These had regenerators which preheated the producer gas and air before combustion and yielded much higher temperatures (*see* SIEMENS). The accompanying figure shows such a furnace. It had a number of combustion chambers, or holes, each holding 4 to 6 crucibles, and heated as many as 100 crucibles at one time. It cut the time of heating to about 2½ hours compared to 6–8 hours by Huntsman coke-fire furnaces. The principle of regeneration was similar to that of the Cowper stove (*q.v.*).

The crucibles, however, remained small, about 100 lb. capacity, because that was all a man could lift out of a hole. They continued to be made of the highest grade of fire clay or a mixture of fire clay and graphite. Usually each plant made its own crucibles which were fired and vitrified before using. The crucibles were about 16 in. high, 10 in. in diameter at the bulge and about 4 to 1 in. thick.

The charge in the crucibles was carefully measured as the only chemical reactions that took place were an increase in silicon content from the reaction between the carbon in the bath with the silica (SiO<sub>2</sub>) of the crucible. There was also a slight drop in the carbon content. Originally the charge was made up of cement steel and low phosphorus wrought iron. Later mixtures of wrought iron and wash metal, high carbon pig iron treated to remove silicon and manganese, were used. After open-hearth steel scrap became available it was used with addition of charcoal or wash metal to make the cheapest charge.

After 1870, Robert F. Mushet added manganese in the charge to lower the oxygen and sulfur content. Once a satisfactory charge was found for a given grade of steel, it was rigidly adhered to. For many years all high-quality tool steel and high-speed steel (*qq.v.*) were made by this process.

The accurately charged crucibles were placed in the furnace and the metal was melted in about an hour. After it melted, carbon

ADAPTED FROM B. STOUTON, "THE METALLURGY OF IRON AND STEEL," REPRODUCED BY COURTESY OF THE MCGRAW-HILL BOOK CO.

CUTAWAY VIEW OF THE SIEMENS GAS-FIRED REGENERATIVE FURNACE

Dotted lines indicate direction of gas flow, which is reversed every fifteen or twenty minutes

monoxide gas was produced and appeared as bubbles at the surface; in the meantime sulfides and silicates were melted and rose to the top of the bath as a slag. When gas evolution stopped the melter judged that the metal was dead or killed and he ordered the crucible to be lifted from the furnace.

When the crucible was taken out of the furnace the cover was removed and most of the slag was swabbed by means of a ball on one end of a long iron rod. The molten metal was then poured into a split cast iron mold, any slag still present being held back with an iron rod.

After 1910, the electric arc furnace gradually replaced the crucible process because larger amounts could be melted, the cost was cheaper and the quality was even better. Heats weighing as much as 50 tons could be melted instead of the 100-lb. charge of the crucible. The last crucible steel plant in the United States was closed down in 1932.

**CRUCIFERAE**, a family of mostly herbaceous flowering plants, which derives its name from the cross-shaped (cruciform) arrangement of the four petals of the flower. The alternative name Brassicaceae is acceptable under the International Code of Botanical Nomenclature. In this dicotyledonous family are found many well-known field and garden plants such as cabbage, cauliflower, collards, broccoli, brussels sprouts, kale, kohlrabi, mustard, radish and rutabaga or swede; wallflower, stock, rock cress, candytuft and alyssum. Many species are annuals; among these are some of the commonest weeds of fields, roadsides and waste places, including shepherd's purse (*Capsella bursa-pastoris*), charlock (*Brassica kaber*), wild mustard or bird rape (*B. campestris*), black mustard (*B. nigra*), hedge mustard (*Sisymbrium officinale*), tumble mustard (*Erysimum cheiranthoides*), garlic mustard or jack-by-the-hedge (*Alliaria petiolata*), mouse-ear cress (*Arabidopsis thaliana*), peppergrass (*Lepidium densiflorum*, *L. ruderale*, *L. virginicum*, etc.), fan weed or field penny cress (*Thlaspi arvense*), false flax (*Camelina microcarpa*) and whitlow grass (*Draba verna*). Other species are biennials producing a number of leaves on a short stem in the first year, and in the second sending up a flowering shoot at the expense of the nourishment

JOHN H. GERARD FROM NATIONAL AUDUBON SOCIETY

FIG. 1.—CURLED MUSTARD (BRASSICA JUNCEA CRISPIFOLIA)

stored in the thick taproot during the previous season. Under cultivation this root becomes much enlarged as in the turnip, rutabaga, etc. A large number of species are perennial and a few (*Cardaria draba*, *C. pubescens*, *Rorippa sylvestris*) have become pernicious field or lawn weeds, vigorously spreading by underground roots.

Plants of the Cruciferae have alternate leaves without stipules and the flowers are arranged in racemes mostly without bracts. The flowers are regular with four free sepals usually arranged in two pairs at right angles; four petals arranged crosswise in one series; and two sets of stamens, an outer whorl of two single stamens and an inner whorl of four arranged in two pairs. In nearly all genera the four inner stamens are longer than the two outer and the whole stamen set is said to be tetradynamous. In exceptional genera (*Warea*, *Stanleya*, *Romanschulzia*, *Macropodium*, *Cibotarium*, etc.), all six stamens are of equal length and usually exceed the other flower parts. The single pistil, which is at the centre of the flower, consists of two carpels joined at their

including northern Africa where some species are a dominant part of the vegetation. The peculiar rose of Jericho (*Anastatica hierochuntica*), which occurs from southern Iran to Morocco, is a resurrection plant. After lying dormant and apparently dead for many months, it can be revived with water to its normal green.

The family is well represented in both Europe and North America—among others by *Nasturtium* (not the gardener's nasturtium; q.v.), *Arabis* (rock cress), *Cardamine* (bitter cress), *Sisymbrium* (hedge mustard), etc.; *S. irio* is London rocket (so called because it sprang up after the fire of London in 1666). *Brassica*, *Diplotaxis* (rocket), *Cochlearia*, *Capsella*, *Thlaspi*, *Cakile* (sea rocket), *Raphanus* and others. There are native North American species in many of these genera and, in addition, European species are widespread as weeds in the western hemisphere. There is a major area of differentiation in western and southwestern North America, the plants occurring particularly on limestone soils. There occur a number of distinctive genera including *Stanleya* (desert plume), *Streptanthus*, *Thelypodium*, *Dithyrea* (spectacle pod), *Physaria* (double bladder pod), *Lesquerella* (cloth-of-gold or bladder pod) and a number of others. *Draba* (whitlow grass) is abundant at high elevations and *Smelowskia* is at the highest elevation of any seed plant on many of the mountain peaks.

Of economic importance are various species of *Brassica*, particularly varieties of *B. oleracea* (cabbage, cauliflower, broccoli, brussels sprouts, kale, collards and kohlrabi), *B. rapa* (turnip), *B. napobrassica* (rutabaga or swede), *B. chinensis* (Chinese cabbage or pakchoi), *B. hirta* (white mustard) and *B. nigra* (black mustard), *Raphanus sativus* (radish), *Armoracia lapathifolia* (horse radish). Water cress and garden cress (*Lepidium officinale*) are used in salads, etc. Dyers woad (*Isatis tinctoria*) produces a blue dye. Common garden ornamentals are wallflower (*Cheiranthus*), stock (*Matthiola*), candytuft (*Iberis*), alison, alyssum, or gold dust (*Alyssum*), rock cress (*Arabis*), dames violet (*Hesperis*), honesty (*Lunaria*) and rainbow rock cress (*Aubrieta*). Many other genera are grown in specialized gardens. (R. C. R.; X.)

**CRUCIFIX**, a model of the cross, on which is an image of the crucified Christ. See CROSS; Crucifix.

**CRUCIFIXION**, in the penal systems of the ancient world, was an important method of capital punishment, particularly among the Persians, Seleucids, Jews, Carthaginians and Romans (up to the emperor Constantine I, who abolished it). In Rome, where it was considered by Cicero the most horrible death, there were various methods of performing the execution. Usually the condemned man, after being whipped, dragged the crossbeam (*patibulum*) of his cross to the place of punishment where the upright shaft was already fixed in the ground. There he was stripped of his clothing and bound fast with outstretched arms to the crossbeam, or nailed firmly to it through the wrists. The crossbeam was then raised high against the upright shaft and made fast to it about 9 to 12 ft. from the ground. Next, the feet were tightly bound or nailed (each foot with a separate nail) to the upright shaft. A ledge (*sedile*) inserted about halfway up the upright shaft gave some support to the body; evidence for a similar ledge (*suppedaneum*) for the feet is rare and late. Over the criminal's head was placed a notice stating his name and his crime. Death, apparently caused by exhaustion or by heart failure, could be hastened by shattering the legs (*crurifragium*) with an iron club, but the medical reasons for death are not fully understood. Crucifixion was thought to be a suitable punishment chiefly for political or religious agitators, pirates, slaves or those who had no civil rights. In 519 B.C. Darius, king of Persia, crucified 3,000 political opponents in Babylon; in 175 B.C. Antiochus IV of Syria whipped and crucified lawbreaking Jews in Jerusalem; c. A.D. 32 Pontius Pilate crucified Jesus of Nazareth; and in A.D. 46 Tiberius Alexander crucified two Galilean rebels, Jacob and Simon ben Juda. See also CROSS; JESUS CHRIST.

FR. E. H. BAILLON "HISTOIRE DES PLANTES"

FIG. 2.—DETAILS OF THE FRUITS PRODUCED BY CRUCIFEROUS PLANTS

edges. The ovary becomes two-celled by the development across it of a septum from one carpel junction to the other on the opposite side. A row of ovules is present at each carpel edge. The fruit is usually a capsule or silicle splitting by two valves from below upward and leaving funiculi with seeds attached to the replum or framework of the septum. The fruits of some genera are indehiscent (remaining closed when ripe). The seeds, lacking endosperm, are filled with a large embryo, the two cotyledons of which are variously folded. In germination the cotyledons come above ground and form the first green leaves of the plant.

Pollination is effected by insects which are attracted to the flowers by exudates of nectar from glands at the base of the stamens and petals. The petals are white, yellow or purple, or of intermediate shades. There are both inbreeding (self-pollinating) and outbreeding (cross-pollinating) species, the latter type apparently predominating in the family.

There is a wide variety of specific mustard oils present in the family and these provide the basis in the foliage, stems or roots for the sharp taste well known in water cress (*Rorippa nasturtium-aquaticum* or *Nasturtium officinale*), mustard greens (*Brassica hirta*) and radishes (*Raphanus sativus*). The common table condiment, mustard, is ordinarily obtained from the seeds of black mustard (*B. nigra*), but the seeds of several different species of *Brassica* are sometimes used as a source. Many species are known to be high in vitamin C content.

Early seamen sailed far out of their normal course to the Kerguelan Islands to gather Kerguelan cabbage (*Pringlea antiscorbutica*) which they consumed for the prevention of scurvy, and the arctic *Cochlearia* is still known as scurvy grass because of its early use by voyagers and explorers.

Cruciferae is a large family containing about 350 genera and about 3,000 species. It is most closely related to the capper family (Capparidaceae). The family is world-wide in distribution, but is most highly developed in the temperate and frigid zones, especially of the northern hemisphere, and as alpine plants. Certain genera are greatly differentiated in the Mediterranean region

**CRUDEN, ALEXANDER** (1699-1770), British author of the best-known biblical concordance, still the standard concordance to the King James version, was born on May 31, 1699, at Aberdeen, Scot., but spent his adult life in or near London. Shortly after graduation from Marischal college, about 1721-22, he was confined for insanity. Never a stable personality, he was confined for two months in 1738 at Bethnal Green, from which he escaped, and again for 17 days in 1753 in Chelsea. After each of the later confinements, he wrote and published pamphlets seeking recompense for the indignities he suffered, dedicating the pamphlets to the king, and gaining only notoriety.

From 1722 to 1732 he was employed variously as private tutor or as reader or amanuensis. At least once he was discharged for ignorance of French pronunciation, a shortcoming he failed to overcome. In 1732 he opened a bookstore and in 1735 became "bookseller to the queen," an unremunerative position. He began his concordance in 1736, and on its publication, Nov. 3, 1737, sent a dedicatory copy to Queen Caroline; her death 17 days later frustrated this attempt for patronage. Enlarged editions of the concordance followed in 1761 and 1769. About 1740 he found his real talent as proofreader, and several editions of Greek and Latin classics owe their excellence to his care.

Influenced by the preaching of Wesley and others, joined with his success as proofreader, he came to believe himself divinely appointed as "Alexander the Corrector" of the nation's manners and morals. Under this delusion he committed many indiscretions that made him an object of ridicule. College students accepted appointments as his deputies, and at Cambridge he was knighted with mock ceremonies. Cruden died in London on Nov. 1, 1770.

His works include, in addition to the concordance, a *Scripture Dictionary*, printed shortly after his death, and a verbal index to Thomas Newton's edition of Milton (1769).

The earliest biography is that by Alexander Chalmers, prefixed to the 6th edition of the concordance (1810). See also E. Olivier, *The Eccentric Life of Alexander Cruden* (1934). (J. W. EL.)

**CRUDEN BAY**, a village and civil parish on the east coast of Aberdeenshire, Scot. Pop. (1961) 1,987. It is situated at the head of Cruden bay, 24 mi. N.N.E. of Aberdeen by road, and has sandy beaches and a fine golf course on the stretch of sands to the north, called Ward of Cruden, at the end of which is the fishing village of Port Erroll. The Bishop's bridge, over the Cruden water, dates from 1697.

Near Ardendrought, not far from the shore, Malcolm II is said to have defeated Canute in 1014. Slains castle (1664), a former seat of the earl of Erroll, lies to the north of Cruden, but the old castle is about 5 mi. S.W. near the point where, according to tradition, the "St. Catherine" of the Spanish Armada foundered in 1588. The Bullers of Buchan (2 mi. N.) is a roofless cave in the rocks, 200 ft. deep and 50 ft. wide, impressive in a rough sea; it was visited by Samuel Johnson.

**CRUIKSHANK, GEORGE** (1792-1878), English artist, caricaturist and illustrator, was born in London, Sept. 27, 1792. By natural disposition and indirectly related circumstances he might be called a born humoristic artist. His grandfather had taken up the arts, and his father, Isaac Cruikshank, was a painter. George followed the family traditions with amazing facility, surpassing others of his period in his ability as an etcher. When his father died about 1811, George, still in his teens, was already a successful and popular artist. All his talents were natural and untrained; outside training, or a serious apprenticeship to art, were dispensed with, under the necessity of working for immediate profit. At times he found cause to regret this lack of academic training, and at intervals he attempted to cultivate accessible knowledge by studying from the antique and drawing from life at the schools. From boyhood he was accustomed to turn his artistic talents to ready account, disposing of designs and etchings to the

print sellers and helping his father with his plates. Before he was 20 his spirited style and talent had secured popular recognition. The contemporary of Gillray, Rowlandson, Alken, Heath, Dighton and the established caricaturists of that generation, George developed great proficiency as an etcher. Gillray's matured and trained skill had some influence upon his executive powers, and when the older caricaturist died in 1815, George Cruikshank had already taken his place as a satirist. Prolific and dexterous beyond his competitors, for a generation Cruikshank delineated Tories, Whigs and Radicals with fine impartiality. Satirical capital came to him from every public event—wars abroad, the enemies of England (for he was always fervidly patriotic), the camp, the court, the senate, the church; low life, high life; the humours of the people, the follies of the great. George Cruikshank's technical and manipulative skill as an etcher was such that Ruskin placed his productions in the foremost rank.

Cruikshank died at 263 Hampstead road, London, on Feb. 1, 1878, and was buried in St. Paul's cathedral.

A vast number of Cruikshank's spirited cartoons were published as separate caricatures, all coloured by hand; others formed series or were contributed to satirical magazines, the *Satirist*, *Town Talk*, the *Scourge* (1811-16) and other ephemeral publications.

In conjunction with William Hone, Cruikshank produced political satires, *The Political House That Jack Built* (1819) and others, reissued by Hone in 1827 under the general title *Facetiae and Miscellanies*.

Of a more genially humoristic order are his famed book illustrations. Early in this series came *The Humorist* (1819-21) and *Life in Paris* (1822), the well-known series of *Life in London*, conjointly produced by the brothers I. R. and G. Cruikshank, and Grimm's *Collection of German Popular Stories* (1824-26), in two series, with 22 inimitable etchings. To the first 14 volumes (1837-43) of *Bentley's Miscellany* Cruikshank contributed 126 of his best plates, etched on steel, including the famous illustrations to *Oliver Twist*, *Jack Sheppard*, *Guy Fawkes* and *The Ingoldsby Legends*. For W. Harrison Ainsworth Cruikshank illustrated *Rookwood* (1836) and *The Tower of London* (1840). The first six volumes of *Ainsworth's Magazine* (1842-44) were illustrated by him with several of his finest groups of etchings. For C. Lever's *Arthur O'Leary* he supplied ten full-page etchings (1844), and 20 spirited graphic etchings for Maxwell's lurid *History of the Irish Rebellion in 1798* (1845).

Of his own books of drawings, mention must be made of *George Cruikshank's Omnibus* (1841) and *George Cruikshank's Table Book* (1845), as well as his *Comic Almanack* (1835-53). The *Life of Sir John Falstaff* (1857-58) contained 20 full-page etchings. The best known of the pictures and illustrations produced by Cruikshank as an enthusiastic advocate of abstinence are *The Bottle*, eight plates (1847), with its sequel, *The Drunkard's Children*, eight plates (1848), and the ambitious work *The Worship of Bacchus*, published by subscription after the artist's oil painting, now in the National gallery, London, to which it was presented by his numerous admirers.

**CRUISER**, a warship built for high speed and great cruising radius, smaller than a battleship or aircraft carrier but larger than a destroyer. The word cruiser was used as a general term to describe frigates of the sailing ship era and also the sloops of war of the early days of steam power. It did not come into general use as a type name in the modern sense until after 1880. Great Britain began to build cruisers at that time and the United States authorized three cruisers in 1883 along with several monitors.

Shipbuilders were making increasing use of steel when the cruisers of the 1880s were begun. An early development was the armoured deck that used steel from two to four inches thick and was intended to protect machinery spaces and magazines against plunging fire. Such vessels were known as "protected cruisers." They were followed by the "armoured cruiser" that had armour belts on both sides, transverse armoured bulkheads fore and aft,

U.S.S. "Brooklyn" which saw service during the Spanish-American War and World War I. Displacement: 10,300 tons

U.S.S. "Oklahoma City," "Cleveland" class guided-missile light cruiser. Displacement: 14,600 tons

"De Zeven Provinciën," "De Ruyter" class cruiser of the Royal Netherlands Navy, rearmed with "Terrier" guided missiles. Displacement: 11,850 tons

H.M.S. "Lion," "Tiger" class cruiser of the Royal Navy, completely air conditioned and electrically driven. Displacement: 11,700 tons

U.S.S. "Long Beach," the U.S. Navy's first nuclear-powered surface ship, a guided-missile heavy cruiser. Displacement: 18,000 tons

"Giuseppe Garibaldi," Italian converted "Garibaldi" class cruiser, armed with the "Terrier" guided missile. Displacement: 11,600 tons

## 20TH-CENTURY CRUISERS

## MODERN CRUISERS

U.S.S. "Albany" firing three missiles in salvo

"Tre Kronor," Swedish Royal Navy cruiser of the "Tre Kronor" class. Displacement: 9,200 tons

U.S.S. "Newport News," "Salem" class heavy cruiser completely air conditioned. Displacement: 21,500 tons

U.S.S. "Albany," "Oregon City" class guided-missile heavy cruiser converted and recommissioned in 1962. Displacement: 17,500 tons

"Sverdlov," U.S.S.R. "Sverdlov" class heavy cruiser, reported converted to guided-missile cruiser. Displacement: 19,200 tons

and one or two armoured decks. "Scout cruisers" were usually smaller and had no armour of any kind.

Before 1900 these three types of cruisers were used to prey on enemy merchant ships, to defend friendly shipping, or to fight enemy cruisers. The advent of the torpedo boat and torpedo-boat destroyer brought a need for higher speeds and greater volume of gunfire if cruisers were to defend themselves against torpedo attacks. Another type, the "battle cruiser," appeared during the early 20th century. It had the big guns of a dreadnought battleship but carried less armour and was capable of higher speeds. "Light cruisers" displaced only about 5,000 tons, frequently no more than 1,500 or 2,000 tons, and carried 3-in. or 4-in. guns. The U.S.S. "Chicago," authorized in 1883, was at first classed as a cruiser, then as a cruiser 2nd line and finally as a light cruiser.

**Limitation of Naval Armament.**—The Washington treaty of 1922 provided that, "No vessel of war of any of the Contracting Parties, hereafter laid down, other than a capital ship, shall carry a gun with a calibre in excess of 8 inches." (See WASHINGTON, TREATIES OF.) This clearly meant that cruisers built after the treaty could not carry guns larger than 8-in. The treaty placed no explicit limit on the size of cruisers, although the definition of a capital ship as one displacing more than 10,000 tons obviously meant that cruisers were to be less than 10,000 tons standard displacement, the equivalent of about 14,000 tons fully loaded. To keep within these limitations cruiser designers employed light metals and other weight-saving devices that increased shipbuilding costs. The treaty restrictions also led to improvements in naval guns. On the basis of main-battery armament, two new classifications of cruisers came into common use: heavy cruisers carrying 8-in. guns, and light cruisers carrying 6-in. guns. Later there developed a third class, anti-aircraft cruisers, with main batteries of dual-purpose guns, usually 5-in. or smaller, that could be used against either aircraft or surface vessels.

The Washington treaty limited the size of guns on cruisers but did not restrict the number of such ships a nation might build. The Geneva conference in 1927 failed to reach agreement on an overall limit to cruiser tonnage, but the London Naval treaty of 1930 covered the subject, extending the 5:5:3 ratio to cruisers as well as to capital ships. In the intervening years the subject caused much discussion and no little international wrangling. Throughout the entire period Britain pointed to her national need for cruisers to protect her vital trade routes. The acceptance of a limit by the British government in 1930 led to further political discussion in England during which the Ramsay MacDonald cabinet defended the action against attacks from the opposition. In view of all that was said in those years about the need for cruisers, an observer in the British Isles in the early 1960s might have been tempted to ask, "How can our commerce be protected now that we have only a very few cruisers?" The answer was that the British government was still relying on ships for the protection of trade, just as it had for centuries, but that many of the ships so employed were no longer called cruisers. The smallest cruisers of the 1960s were of about the same tonnage as the largest ones earmarked for commerce protection in the early years of the 20th century. There were no "cruisers" of 1,200 to 5,000 tons in 1960, but the Royal Navy had destroyers, destroyer types and other vessels available for duties that had once fallen to the smaller cruisers.

The resurgence of German naval power, one of the major developments of the 1930s, helped destroy the treaty limitations on naval armament. By the treaty of Versailles, Germany had been forbidden to acquire armoured ships displacing more than 10,000 tons. To get around this restriction German naval architects created the so-called pocket battleships, "Deutschland," "Admiral Scheer" and "Admiral Graf Spee." These ships conformed to the Versailles limitation on tonnage but they mounted 11-in. guns that far outclassed the 8-in. weapons on cruisers built by the signers of the Washington treaty. This gain in firepower, however, was made only by sacrificing armour and speed; many U.S. and British naval officers felt that mounting 11-in. guns on vessels of this type was a mistake. Germany laid the keels of two battle cruisers, "Scharnhorst" and "Gneisenau," in 1934 to serve as com-

merce raiders and to attack convoys. In Dec. 1941 the United States began to build a similar type classed as large cruisers.

**Naming of Cruisers.**—In accordance with various acts of Congress, the U.S. navy names cruisers for principal U.S. cities and towns, but there have been a few exceptions to the rule. The "Canberra" was named for the capital of Australia because an Australian cruiser of that name was lost while serving with U.S. ships at the battle of Savo Island, Aug. 9, 1942. The frigate "Norfolk," begun in 1949, was originally classified as a cruiser to be used for antisubmarine work. She retained the name after being reclassified as a frigate. The names "Alaska," "Guam" and "Hawaii" were assigned to large cruisers begun in 1941-42. "Hawaii" was 82% completed when work was suspended after 1945.

The U.S. navy uses CA to designate a heavy cruiser, or CAG if equipped with guided missiles. A light cruiser is CL, and with guided missiles becomes CLG. An anti-aircraft cruiser is CLAA. Nuclear-powered guided missile cruisers of the "Long Beach" class are designated CG(N).

The Royal navy has named cruisers for famous ships of the past, for great fighting men or for cities or colonies. For example, the three cruisers completed in 1959 were named "Lion" (17th of her name), "Tiger" (15th) and "Blake" (3rd). Cruisers of the "Southampton" class were named for cities in the British Isles; cruisers of the "Mauritius" class were named for colonies.

**Modern Cruisers.**—Cruisers of the "Tiger" class (1959, first such British ships built since 1945) had a complement of 60 officers and 980 men. Their fully automatic 6-in. turrets had a rate of fire far in excess of any previous British cruisers. They carried twin 3-in. guns and Bofors 40-mm. anti-aircraft guns. Their full-load displacement was more than 11,000 tons and their speed exceeded 30 knots. British cruisers completed between 1937 and 1945 had displacements ranging from 11,100 to 14,930 tons.

The U.S.S.R. had more than 35 light cruisers in the early 1960s. Some of these displaced nearly 20,000 tons, but the heaviest armament was the 7.1-in. gun. Many were also fitted for minelaying operations.

The U.S. navy in the early 1960s had several guided missile cruisers in commission, including "Boston" and "Canberra," the first ships to be so designated. On Dec. 2, 1957, the keel was laid at Quincy, Mass., for the first ship to be designed and built as a guided missile cruiser and the first surface vessel in the U.S. navy to employ nuclear power. The "Long Beach," launched in July, 1959, displaced 14,000 tons but was larger than other ships of that tonnage because the weight of her nuclear power plant and fuel was less than that of conventional systems. She required refueling not oftener than once in six months and her cruising radius was many times that of any earlier ship of any type. Her dimensions were approximately 700 ft. by 75 ft. by 26 ft. She carried three types of guided missiles as well as surface-to-surface anti-submarine weapons.

**Prospective Developments.**—The navies of the world have ceased to build battleships and have scrapped or decommissioned almost all of the remaining vessels of that type. There is little danger, however, that cruisers will suffer the same fate. In offensive power the "Salem" class of cruisers surpasses H.M.S. "Dreadnought" of 1906, and ships of this class are as large as that battleship was. With their rapid-fire guns and automatic loading systems modern cruisers have far higher rates of fire, greater range and superior fire control. Although their armour would appear to be less, their protection is probably relatively greater. The general performance of all cruisers in the test of battle between 1939 and

Cruisers of All Types

\*Afterward scrapped or transferred.

1945 was well up to reasonable expectations. While the U.S. navy lost ten cruisers between Dec. 7, 1941, and Oct. 1, 1945, more than that number suffered severe damage and still managed to reach port. With nuclear power plants giving them almost unlimited cruising radius, practically eliminating the refueling problem that had been the major limiting factor in previous operations, and with probable developments in guided missiles the role of the cruiser would seem to be expanding.

See AIRCRAFT CARRIER; BATTLESHIP; DESTROYER; SHIP; see also references under "Cruiser" in the Index volume.

**CRUMHORN**, a wind instrument, now obsolete, that flourished during the period 1500-1650 (French *cromorne*, *tournebout*). Its name is derived from the old English *crump*, crooked. It consists of a wooden pipe curved upward at the lower end, with a small, cylindrical bore and fingerholes like those on the recorder. It is sounded by a double reed enclosed in a wooden cap with blowing orifice in the top. See WIND INSTRUMENTS: *Reed Instruments*. (A. C. Ba.)

**CRUSADES** (Sp. *cruzada*, "marked with the cross") is the name given to a series of wars undertaken by the Christians of western Europe with the authorization of the papacy from 1095 until the mid-15th century for the purpose of recovering the Holy Sepulchre at Jerusalem from the Muslims and defending possession of it. In a broader sense a crusade was a war sanctioned by the papacy and directed against anyone whom it declared to be the enemy of Christ.

**Causes.**—The immediate cause of the crusades was the interruption of the pilgrim traffic to the Holy Sepulchre as a result of the advance of the Seljuk Turks (see SELJUKS) in the 11th century. In 1055 the Seljuk chieftain, Toghrul Beg, forced his nominal master, the Abbasid caliph at Baghdad, who was a Sunnite Muslim, to grant him the title of sultan. After the battle of Manzikert (q.v.) in 1071, nomadic bands of Turks overran the ancient Byzantine territory of Anatolia, making the journey of pilgrims from Europe increasingly difficult. After the death of the able sultan Malik Shah in 1092 his amirs began fighting over Syria, Palestine and the other Abbasid provinces, causing further disruption of pilgrim traffic. Since expeditions of pilgrims from Europe were becoming more frequent and included larger numbers of people, such interruptions caused great distress.

A second and general cause of the crusades was the release of expansive energy in western Europe. For about 200 years the west had endured the attacks of the Saracens, the Vikings and the Magyars. Then, about the beginning of the 11th century, the Vikings and the Magyars were Christianized, a rudimentary form of law and order was established by the great feudal princes and prelates, commerce began to revive and money to circulate.

The church was stirred at the same time by the progress of the Cluniac Benedictine reform in the monasteries by the great increase in the number of pilgrimages and by a quickening of the tempo of the religious wars conducted against the Muslims in Spain and Sicily. Toledo in Spain was captured in 1085; the Arab base of Mahdia in Tunisia was taken by the Genoese, the Pisans and their allies from other Italian cities in 1087; and the last Muslims were driven from Sicily in 1091. These campaigns were blessed by the papacy, a precedent for the future.

Most important of all were the plans of Pope Urban II, a disciple and protégé of Pope Gregory VII and a prominent leader of the Cluniac reform movement. The Cluniacs wished to institute a stern, pure and universal discipline in the church, to free it from all taint of feudal control, to enable the pope as the vicar of Christ to rule the church universal and to channel the activities of mankind into the service of God. Rule of the church universal would imply not only control in western Europe but

also the healing of the diplomatic breach, the schism of 1054 between the papacy and the Byzantine patriarch and emperor, and ultimately a recognition of papal supremacy over the whole church in both east and west.

Upon becoming pope in 1088, Urban II resumed contacts with the Byzantines, but since he and the Byzantine emperor Alexius I Comnenus were both at first occupied in strengthening their positions at home nothing further of importance happened between them for a few years. Then, in the spring of 1095, Urban called a council at Piacenza to discuss ecclesiastical affairs. To this council Alexius sent an appeal for recruits for his army to fight the Turks (his predecessor, Michael VII, had made a similar appeal to Gregory VII in 1073 in offering to discuss healing the breach of 1054). Urban brought this problem to another church council which met at Clermont, in Auvergne, in Nov. 1095. However, instead of asking for volunteers for the Byzantine army he called for a papal army, as Gregory had considered doing on the previous occasion. Its symbol was to be the cross and its leader a papal legate. Its mission was to help Alexius drive the Turks from Anatolia, and then to go on to recover possession of the Holy Sepulchre at Jerusalem, as Gregory VII had originally planned. This latter purpose was not among the plans of Alexius, who had more immediate objectives. There is no evidence that Urban raised the troublesome issue of papal supremacy on this occasion and certainly none that he ever modified the principle. The conduct of the subsequent crusade indicates that he intended to recognize and restore the Greek Orthodox clergy as the crusade progressed. This was essential if the breach with the Byzantines were to be healed.

**First Crusade.**—Urban's appeal for a crusade was far more successful than he expected. There arose not only an army in southern France but also several in northern France and one in Apulia in southern Italy, all led by powerful feudal princes; there were also several bands of common people with popular leaders. The large army of Provençals under the rich and powerful Raymond IV (q.v.), count of Toulouse, was accompanied by Adhemar de Monteil, bishop of Le Puy, the papal legate. It was Raymond's ambition to be the military leader of the crusade, a kind of *advocatus* under the papal legate. Contingents from the north were led by Robert II Curthose, duke of Normandy; by Robert II, count of Flanders; and by Godfrey (q.v.) of Bouillon, duke of Lower Lorraine—all with large forces; and also by Stephen Henry, count of Blois, and by Hugh, count of Vermandois, with negligible forces. From the Norman duchy of Apulia came Bohemund (q.v.), son of Robert Guiscard, with a small but excellent army. Such leaders were not disposed either by rank or by temperament to take orders from Raymond or from one another, and it was clear that it would take much tact on the part of the papal legate to control them.

These forces of crusaders, or Franks as they were called, arrived at Constantinople at intervals from July 1096 to May 1097. Godfrey of Bouillon went across Hungary, Raymond through Dalmatia and the others via Apulia and Albania. Alexius, who had simply wanted soldiers for his armies, received instead hordes of ill-disciplined fighting men and, in addition, pilgrims, clergy and other noncombatants, under western leaders whom he could not control. Bohemund, who had accompanied Robert Guiscard in a dangerous invasion of the Byzantine possessions in Albania and Greece as recently as 1081-85, now blandly requested of Alexius the office of grand domestic of the east, which would have made him imperial viceroy for all the lands that the crusaders might conquer. There is no record that Alexius granted any such request. He did, however, exact from the Frankish princes an oath that they would return to him all former imperial territories taken by the Turks which they might reconquer and also imposed on them an oath of allegiance with respect to anything further that they might recover. This meant that he expected the return of the Anatolian peninsula and the city of Antioch but would be content with a form of feudal suzerainty over any other territory, such as Palestine if the crusaders cared to go there. The Frankish princes agreed with varying degrees of willingness, the wily Bohemund with alacrity. Raymond, suspicious of an oath that

WERNER BRAUN

GOLDEN GATE, EAST WALL OF JERUSALEM, OUTSIDE THE HARAM AREA

might put him under a grand domestic of the east, would agree only not to permit harm to the life and honour of Alexius.

The Franks and Byzantines had hardly begun their journey across Asia Minor when Frankish resentment was aroused at the emperor's introduction of soldiers into Nicaea after its surrender in June 1097, in order to prevent the town from being looted by the Frankish soldiers. His action intensified their instinctive dislike of the Greeks, whose religious customs were different from and whose cultural level was higher than their own. As the crusaders, having defeated the Seljuks at Dorylaeum (near the modern Eskisehir) in July, moved across the Anatolian highlands, Alexius turned to the reoccupation of his former provinces, sending on only a token force with the crusaders. This seemed like desertion to the common soldiery, but it was different when Godfrey's brother Baldwin of Boulogne, the future Baldwin I (*q.v.*) of Jerusalem, detached himself from the main army at Marash and set himself up as the ruler of the Armenians of Edessa, across the Euphrates, in March 1098; this seemed a valiant act and set an example which Bohemund was eager to follow.

Meanwhile the main army of the crusaders reached the environs of Antioch, the metropolis of northern Syria, in Oct. 1097. As a result of the jealousies and anarchy that had developed among the amirs and other governors of the Seljuk sultans after the death of Malik Shah, the ruler of Antioch, Yaghi-Siyan, got very little support from elsewhere. Yet, thanks to the strength of his position, to quarrels among the Frankish princes and to the decision of Alexius to occupy as much of Anatolia as possible and not come to Antioch until spring, he was able to hold out until June 1098. When Alexius finally started he was turned back at Philomelium (Aksehir) in June by the alarmist reports of the deserter Stephen Henry of Blois regarding the strength of the *atabeg* (regent) Kerbogha of Mosul, then marching to relieve Antioch. Alexius' decision was momentous, for he not only lost his chance to recover Antioch but he forfeited most of the lingering respect that he still enjoyed among the Franks.

During May 1098 Bohemund worked upon the crusaders' suspicions of Byzantine perfidy and wrung from the majority of the leaders the promise that if Alexius did not arrive the man who might effect the capture of the city should have it. Raymond, mindful of the pope's desire for good relations with the Byzantines, would not agree. Nevertheless Bohemund completed secret negotiations for the betrayal of the city, and Antioch was taken on June 3, 1098—not a moment too soon. Kerbogha arrived on June 5 and the besiegers became in their turn the besieged. Bohemund, however, managed to defeat Kerbogha's forces on June 28 and the Franks were saved.

The future of Antioch was now hotly debated between Bohemund, who held most of the city, and Raymond. Their quarrel delayed the further progress of the crusade for some months. Finally popular impatience compelled the princes to resume their journey toward the Holy Sepulchre in Nov. 1098. Bohemund turned back just after Christmas and, ejecting the guards that Raymond had left at Antioch, took complete possession of the city. In thus founding the second Frankish state in the east (after Edessa), he widened the breach with the Greeks, which the pope had hoped to heal.

After the long delay around Antioch the rest of the journey to Jerusalem was quickly accomplished. The Arab governors along the coast of Syria, most of whom were nominally subject to the Fatimid caliph of Cairo, were glad to provide the Franks with markets and food in return for security. However, when the crusaders reached Jerusalem itself on June 7, 1099, they encountered stiffer opposition, Jerusalem being after all also a holy city to the Muslims. Taking advantage of the Frankish hostilities against the Turks, the Shi'ite Fatimid government had seized the city from the Sunnite Turks the year before and was resolved to defend it. Nevertheless, the crusaders took Jerusalem by storm on July 15 and a horrible massacre of Muslims and Jews ensued. Under such circumstances the Holy Sepulchre was recovered.

**Organization of the Latin States.**—With the conquest of Jerusalem the establishment of a government was the next task. Godfrey of Bouillon was chosen *advocatus* (defender) of the Holy Sepulchre. The title was in deference to ecclesiastical wishes for a church state rather than a monarchy. The more secular or feudal interests were served by the choice of a willing partisan, Arnulf, chaplain to the duke of Normandy, as patriarch. No thought was given to restoring a Greek patriarch in the city.

Arnulf was soon set aside through the influence of Bohemund and of Archbishop Daimbert of Pisa, who arrived in Dec. 1099 ostensibly for the Christmas devotions at the Holy Sepulchre. The archbishop, playing upon Godfrey's need for naval support from Pisa in order to conquer the Palestinian ports, got himself chosen patriarch of Jerusalem and on that basis claimed to be the feudal suzerain of both Bohemund and Godfrey. This satisfied Bohemund, who went back to Antioch with a Latin Church sanction for his usurpation of that city from the Greeks, but Godfrey was victimized. Daimbert tried to rule both church and state at Jerusalem, to ignore Godfrey and even to induce him to give up the city of Jerusalem. Godfrey died on July 18, 1100, before an open break with Daimbert occurred.

Baldwin, Godfrey's brother, was summoned from Edessa by Arnulf and others as Godfrey's successor. Baldwin forced Daimbert to crown him king at Bethlehem on Christmas day, 1100. Then, step by step, he drove Daimbert from the country (1102) and gradually associated the royal title with Jerusalem, the holy city. In all this he was abetted by Arnulf, who eventually became patriarch again in 1112. Thus the cause of feudal monarchy triumphed at Jerusalem over that of an ecclesiastical state.

Besides Jerusalem three other Latin Christian states were established in the east. These were the countship of Edessa, the principality of Antioch and the countship of Tripoli (Tripoli was conquered during the years 1102–09 by the adherents of Raymond of Toulouse). Government in all three was feudal and was probably similar to that in Jerusalem.

In the case of Jerusalem in particular and to a lesser degree in that of Antioch there are elaborate records (the *Assizes*) of customs and laws written down largely in the 13th century. Those of

Jerusalem indicate a king, a group of tenants-in-chief belonging to a royal feudal council (the *haute cour*), a complete Latin Church hierarchy, an establishment of monasteries, a royal domain, a number of towns and a set of classes and estates all with elaborately defined rights and usually with courts to protect those rights. Three circumstances are noteworthy. First, the king was elected by the *haute cour* and was regarded as *primus inter pares* by its members. Second, the Italian colonies in the ports had almost independent extraterritorial rights, usually granted in return for naval aid in conquering the ports. Third, there were three great military orders of knighthood, the Templars, the Order of the Hospital of St. John of Jerusalem and in later times the Teutonic Order (*q.v.*). Largely maintained by their own funds from Europe, the knights garrisoned many of the great castles which guarded the frontiers, and under resident grand masters enjoyed a large degree of independence.

Despite these limitations to his authority the king of Jerusalem could still wield much power if he were an able man. His royal domain could supply about two-fifths of the secular knights of the kingdom, he commanded all the armed forces in time of war and he usually controlled the selection of the patriarchs and the high churchmen. Furthermore, his guardianship of Jerusalem and the Holy Sepulchre gave him great advantages. He could claim moral leadership over the other three Latin states and often

exercised it. Baldwin I was actually suzerain of the counts of Edessa and Tripoli. Jerusalem received most attention from the west and from the pope. To it came pilgrims, new crusaders and money. Through the pope the king could exert some influence and control over the other three states, over the grand masters of the military orders and over the patriarch.

With the exception of Edessa the crusader states lay along the coast. Since they all had to be constantly supplied and maintained from Europe, there was a continuous need for preaching crusades in Europe. The governing class of the four Latin states never numbered more than 2,000–3,000 western European nobles and clergy, mostly French in origin and speech. They ruled a heterogeneous population of native Muslims and Christians, the former more numerous in the kingdom of Jerusalem, the latter in the north. The countryside was divided into *casalia* (estates) worked by the native peasantry. In the seaports were native merchants and artisans and colonies of Genoese, Pisan and Venetian merchants and mariners. In time of peace Muslim merchants from the interior were usually welcomed and the Franks quickly adopted a tolerance toward Muslims and their ways, which always astonished idealistic pilgrims and crusaders fresh from Europe.

Tables I–IV show the rulers of the four Latin states.

**Relations With the Muslim States.**—Once the Franks were established in the east they faced the problem of survival among the Muslim states. There was much in their favour. The Abbasid caliphs of Baghdad and their Seljuk sultans were largely indifferent to Syria and Palestine, which lay on the periphery of their interests. Accustomed to Christians, especially to Byzantines, they at no time regarded the petty crusader states as dangerous and never attempted to drive out the Franks. This was also largely the attitude of the caliphate of Cairo. After a futile attack on the Franks of Jerusalem in 1105, al-Afdal, the vizier of Egypt, returned to a purely domestic policy. In Syria itself the local Turkish regimes at Aleppo and at Damascus were mutually hostile and sometimes ready to ally themselves with the Franks against each other. Under these circumstances the wisest policy for the Franks would have been to live with the neighbours who were willing to tolerate them and certainly never to let the Muslim states unite in a *jihad* or holy war.

Consequently, when Imad-al-Din (Zangi), *atabeg* of Mosul, seized Aleppo in 1128 and then tried to get possession of Damascus in order to start a *jihad*, the Franks should have helped the Burid dynasty of Damascus retain its independence. Instead they harassed Damascus from the south while Zangi invaded its lands in the north. In 1140 they had to be paid by the government of Damascus to save the city from a siege by Zangi, although it was in their own interest to keep Damascus free. Then in 1144 Zangi attacked Edessa, the capital of the first crusader state, and captured it. Zangi died in 1146, but his son Nureddin (Nur-al-Din Mahmud) continued his work for a holy war.

**Second Crusade.**—The fall of Edessa shocked western Europe, and Pope Eugenius III issued a call to arms, the second crusade. The pious Louis VII of France took the cross, as did the German king Conrad III—the latter in response to the preaching of Bernard of Clairvaux. They departed in the spring of 1147 with high hopes, traveling through Hungary, Conrad going on ahead. When Conrad's army reached Asia Minor, it was ambushed and destroyed by the Turks near Dorylaeum on Oct. 25, 1147. The army of Louis suffered almost as severely near Laodicea in Pisidia early in Jan. 1148.

Nevertheless, by the spring of 1148 both monarchs had got through with very small forces by sea, Louis to St. Symeon, near Antioch, and Conrad to Acre. At Antioch the prince, Raymond (*q.v.*) of Poitiers, uncle of the queen of France, Eleanor of Aquitaine, tried hard to induce Louis to operate against Aleppo, Nureddin's key base in northern Syria. This was the soundest possible military advice and might have helped Edessa, whose fall had led to the crusade. Louis, however, was piously determined to campaign closer to the Holy Sepulchre. He departed, moreover, with such suspicions about his queen's relations with her uncle Raymond that he procured an annulment of their marriage when they eventually returned to France.

TABLE I.—Kingdom of Jerusalem

Ruler	Right of succession	Reign
Godfrey (of Bouillon) . . .		1099–1100
Baldwin I (of Boulogne) . . .	Brother of Godfrey	1100–18
Baldwin II (of Bourcq) . . .	Cousin of Godfrey and Baldwin I	1118–31
Melisande, heiress . . .	Daughter of Baldwin II	1131–52
Fulk (of Anjou) . . .	Consort of Melisande	1131–43
Baldwin III . . .	Son of Melisande and Fulk	1143–63
Amalric I . . .	Brother of Baldwin III	1163–74
Baldwin IV . . .	Son of Amalric I	1174–85
Baldwin V . . .	Nephew of Baldwin IV	1185–86
Sibyl, heiress . . .	Daughter of Amalric I, mother of Baldwin V	1186–90
Guy (of Lusignan) . . .	Consort of Sibyl	1186–92
Isabella (I), heiress . . .	Sister of Sibyl	1192–c. 1205
Conrad (of Montferrat) . . .	Consort of Isabella	April 1192
Henry (of Champagne), not styled king . . .	Consort of Isabella	1192–97
Amalric II (of Lusignan) . . .	Consort of Isabella	1198–1205
Mary, heiress . . .	Daughter of Isabella and Conrad	1205–12
John (of Brienne) . . .	Consort of Mary	1210–25
Isabella (II, or Yolande), heiress . . .	Daughter of Mary and John	1212–28
Frederick (II, as emperor) . . .	Consort of Isabella	1225–43*

\*Frederick was crowned in Jerusalem in 1229, but his son by Isabella, the German king Conrad IV, could be regarded as having inherited the kingdom at the latest on his coming of age in 1243. Long after the fall of Jerusalem itself to the Muslims (1244), the royal title was disputed between (1) Frederick's descendants, of the house of Hohenstaufen; (2) the kings of Cyprus, of the house of Lusignan, descendants of Amalric II and also of Henry of Champagne's daughter Alice; and (3) the Angevin kings of Naples, descendants of Charles of Anjou, who in 1277 purchased the claims of Mary of Antioch, grandchild of Isabella (I) and Amalric II through their daughter Melisande, wife of Bohemund IV of Antioch.

TABLE II.—Principality of Antioch

Bohemund I . . .	1098–1100	Baldwin, regent again . . .	1131
Tancred, regent . . .	1101–03	Fulk (of Jerusalem), regent . . .	1131–36
Bohemund I, restored . . .	1103–04	Raymond (of Poitiers) . . .	1136–49
Tancred, regent again . . .	1104–12	Raynald (of Châtillon) . . .	1153–60
Roger, regent . . .	1112–19	Bohemund III . . .	1163–1201
Baldwin (II of Jerusalem), regent . . .	1119–26	Bohemund IV . . .	1201–33
Bohemund II . . .	1126–31	Bohemund V . . .	1233–52
Constance, heiress . . .	1131–63	Bohemund VI . . .	1252–68*

\*Fall of Antioch.

TABLE III.—County of Edessa

Baldwin I (of Boulogne) . . .	1098–1100	Joscelin I (of Courtenay) . . .	1118–31
Baldwin II (of Bourcq) . . .	1100–18	Joscelin II (of Courtenay) . . .	1131–44*

\*Fall of Edessa.

TABLE IV.—County of Tripoli

Raymond (IV of Toulouse), begins conquest . . .	1102–05	Bohemund (later IV of Antioch) . . .	1187–1233
William . . .	1105–09	Bohemund (V of Antioch) . . .	1233–52
Bertrand, established as count . . .	1109–12	Bohemund (VI of Antioch) . . .	1252–75
Pons . . .	1112–37	Bohemund VII . . .	1275–87
Raymond II . . .	1137–52	Lucia, heiress as Bohemund VII's sister . . .	1288–89*
Raymond III . . .	1152–87		

\*Fall of Tripoli.

SYRIA DURING THE PERIOD OF THE CRUSADES

After Conrad and Louis had performed their devotions at the Holy Sepulchre they and the Franks of Jerusalem decided to attack Damascus. The chief reason for this decision was greed for rich fiefs. No thought was given to the fact that Damascus protected Jerusalem and the other crusader states from Nureddin, who was making mounting efforts to acquire it and enlist it in the holy war.

The siege of Damascus was a fiasco. The invaders attacked the city from the south for three days and then changed to the east, where they ran short of water. All this time they were locked in bitter disputes over whether Thierry of Alsace, the protégé of Conrad and Louis, or the Franks of Jerusalem should have Damascus and its rich lands. As a result the crusaders abandoned the siege on July 28, 1148, after four days and departed.

The results of the second crusade were as follows. The spell of success enjoyed by the Franks as a result of the first crusade was broken, and they lost prestige in the eyes of the Turks. There was increased resentment in western Europe against the Byzantines, who were held responsible for the disasters in Anatolia. In Damascus the population began seriously to question the wisdom of co-operation with the Franks, and to favour Nureddin and his policy of *jihad* instead.

**Nureddin's Achievement and the Rise of Saladin.**—After the second crusade Nureddin relentlessly continued his father's policies of uniting the Muslims and attempting to drive the Europeans out of Palestine and Syria. In 1149 he defeated and killed Raymond of Antioch at Inab, permanently weakening the principality of Antioch and making easier the operations against Damascus. His great victory made him appear to Sunnite Muslims as the champion of their faith. He cultivated this feeling, patronizing mosques and schools which taught the need of Muslim unity. This made it increasingly difficult for the regime at Damascus to maintain its independence by the policy of co-operation with the Franks. Starting in 1150 and excepting 1152, Nureddin annually invaded the rich lands of Damascus. He restrained his forces from engaging in much plundering, declared himself the true champion of Islam and thus attempted to shame the government inside the city.

In 1153 Baldwin III (*q.v.*), king of Jerusalem from 1143 to 1163, captured Ascalon, the Egyptian fortress 40 mi. S.W. of Jerusalem. Although the caliph of Egypt was a Shi'ite the fall of Ascalon was too much for Sunnite feeling in Damascus. The next year when Nureddin appeared the people of Damascus opened

their gates without a fight. Syrian Islam was now united against the Franks.

Events now centred on the control of Egypt. The viziers of the Fatimid caliphs had since 1105 pursued a mainly domestic policy. It was essential for Nureddin to control Egypt in order to encircle the Franks and it was equally necessary for the latter to intervene in Egypt in order to prevent this. Amalric I (*q.v.*), king of Jerusalem from 1163 to 1174, took advantage of court factionalism in Cairo to invade the delta in 1163, 1164, 1167 and 1168. Each time Nureddin sent in his Kurdish general Asad-al-Din Shirkuh to support the opposing side. In Jan. 1169 Shirkuh succeeded in entering Cairo and, although a Sunnite, became the vizier to the Fatimid caliph. Shirkuh died two months later and was succeeded by his nephew Saladin (*q.v.*; Salah-al-din Yusuf ibn Ayyub). In 1171, on order from Nureddin, Saladin proclaimed the authority of the Abbasid caliphate in Egypt. At last the Muslims of Iraq, Syria and Egypt were in religious and political harmony and the *jihad* had become a distinct probability.

When Nureddin died in 1174 there ensued a struggle for power among his family and officers, and the unity that he had built up appeared to vanish. Saladin at once secured control of Damascus. It was a decisive stroke, for it enabled him to operate against Aleppo and Mosul from Damascus and Egypt. He soon acquired the mantle of moral authority as leader of the Muslims by his consistent conduct and because the heirs of Nureddin by contrast now stood for Muslim division and weakness. By 1183 Saladin gained control of Aleppo and by 1186 he became overlord of Izz-al-Din of Mosul. Thus the Muslims were again united and able to hem in the Franks by land. During this time Saladin avoided serious trouble with the Franks, built up his army, wooed the Italian cities with commercial treaties with Egypt and played on the reciprocal suspicions of the Byzantines and of the Franks.

**Saladin's Conquest of Jerusalem.**—Jerusalem, Tripoli and Antioch, the three remaining crusader states, which Saladin now planned to eliminate, had impressive advantages. They occupied a central position, with huge castles guarding the frontiers and sea connections with western Europe, and they possessed cavalry and infantry intimately experienced in the ways of the Turks and Egyptians. What they lacked was unity and common sense.

The Franks of Jerusalem were plagued by an internal struggle for power. Baldwin IV (*q.v.*), king from 1174 to 1185, was fatally ill with leprosy and his nephew and heir, the future Baldwin V, was still a child. The barons of the kingdom, led by Raymond

in the 14th and 15th centuries and to the gates of Vienna in the 16th and 17th. Only in Spain and along the eastern Baltic coast did the crusading movement permanently extend Christian conquest.

Islam, however, was most adversely affected by the crusades. Whereas originally the Muslims had been quite tolerant of the Christians and Jews whom they conquered, the harsh treatment of Muslims by the crusaders during a period of three or four centuries inevitably made the Muslim rulers in turn, especially the Mameluke and Ottoman sultans, less tolerant of the unbeliever. Furthermore, the crusaders must share the blame with the Turks, Mongols and Mamelukes for that constant battering of the Arab aristocracies which gradually reduced them from an enlightened and urbane culture, superior to that of western Europe in tolerance and in breadth of intellectual interest, to a narrow religious conservatism under which secular learning declined. By the time the crusades were over, intellectual leadership had passed from the Arabs to western Europe, but this was a result not so much of the crusades as of the transfer of Arabic scholarly knowledge through Spain and Sicily, and of the Renaissance.

In Europe the effects of the crusades were many and varied. Western Christianity naturally suffered from the stain of intolerance. This showed itself in persecutions—of Jews as soon as the first crusade began, of Muslims and Orthodox Christians throughout the period of the crusades and of the Albigensians and enemies of the papacy such as the Hohenstaufens in Italy in the 13th century. In their onslaught on the Hohenstaufens the popes laid themselves open to the charge of discrediting not only the crusading ideal but also their own office. The crusades affected the Western Church in many other ways, some good and some bad. There was an initial enhancement of papal prestige, an increase in the power of the church to tax and to raise money, an extension of the canon law (particularly in the right to protect crusaders and their property), an increase in the use of indulgences and, certainly, a vast outpouring of faith not only by the crusaders and pilgrims but also by their friends and relatives who remained at home.

The trade across the Mediterranean between east and west was greatly stimulated by the crusades. Ships which set out from western European ports carrying men and goods in bulk, such as grain, timber and horses, had on the return journey cargo space to sell cheaply. Hence the freight rates on all types of eastern luxury goods were lowered. Spices, fabrics of all kinds, tapestries, cushions, rugs, drugs, fruits, sugar, jewelry, perfumes, glass and fine steel products came to the west in larger quantities than ever before. This commerce encouraged the development of a money economy, which had profound results on the rise of the merchant class, on the standard of living of the nobles, on serfdom and manorial economy and on the development of royal finance and government. Commerce as well as the need to transfer pilgrim and crusader funds prompted both Italian merchants and the Knights Templars to develop banking techniques. There was also a valuable increase in both navigational and geographical knowledge.

The nobility of the west was affected in various ways by the crusades. Knights learned to use heraldic emblems and coats of arms in order to identify themselves when far from home. They imported into Europe a knowledge of heavy stone masonry learned from the Byzantines and Arabs and soon huge stone castles (see CASTLE) and stone churches began to appear in western Europe. With the castles came a knowledge of mining, sapping and siege machinery. Some nobles were adversely affected by the sale of charters to towns in order to raise money for crusades, or by the loss of property for failure to pay crusader debts, or were ruined by extravagance in the purchase of oriental goods.

One important consequence of the crusades in the west was a vast literature in the form of storytelling, legends, songs, chronicles and historiography. Many of the songs and tales were in the vernacular, especially in French. There was a rich development of the things of the imagination, as can be seen not only in the *chansons* of the crusades but also in the kindred stories of Charlemagne and King Arthur, with their new presentation of the ideal of Christian knighthood and chivalry. Western Europe, on the

other hand, did not contribute much of intellectual value to the east, for at the time of the crusades it had little to give.

**Contemporary Historiography.**—The anonymous *Gesta Francorum et aliorum Hierosolymitanorum* and the works of Raymond of Aguilers and of Fulcher of Chartres are eyewitness accounts of the first crusade. Caffaro de Cashifellone (*De liberatione civitatum orientis*), Ekkehard of Aura (*Hierosolymita*) and Ralph of Caen (*Gesta Tancredi*) were slightly later eyewitnesses. The account by Albert of Aix, which extends to 1120, is of great importance for its length and detail. For the period from 1127, when Fulcher's account ends, to 1184, William of Tyre is of the highest value. Historians of the second crusade were Odo of Deuil (on the expedition of Louis VII of France) and Otto of Freising. The period beginning with the fall of Jerusalem in 1187 and the third crusade was recorded in the *Chronique d'Ernoult et de Bernard le Trésorier* and in the *Estoire d'Eracles* by continuators of William of Tyre; in the *Libellus de expugnatione Terrae Sanctae* attributed to Ralph of Coggeshall; and in the *Estoire* of the Norman chronicler Ambrose, to which the *Itinerarium peregrinorum et gesta regis Ricardi* is closely related. Further information is to be found in the works of Benedict of Peterborough, Ralph of Diceto, Roger of Hoveden, William of Newburgh, Richard of Devizes, Rigord and William la Breton. For the fourth crusade Geoffrey de Villehardouin and Robert de Clari (*La Conquête de Constantinople*) are important authorities. The fifth crusade is described by Oliver of Paderborn (*Historia Damianiana et Epistulae*) and by Jacques de Vitry (*Historia Hierosolymita*). Jean, sieur de Joinville, gives an incomparable account of Louis IX's crusade. For the later part of the 13th century, there are successive recensions of the *Estoire d'Eracles* (which carry the story down to 1277), the *Annales de Terre Sainte* and the *Gestes des Chiprois*, the latter two works being related to one another.

From the Byzantine point of view, the *Alexiad* of Anna Comnena, daughter of the emperor Alexius I, provides an eyewitness account written about 40 years after the first crusade. Other Byzantine historians of the 12th century were John Cinnamus and Nicetas Choniates. In Armenian there is the chronicle of Matthew of Edessa, written before 1140. Other Eastern Christians who left accounts were Michael the Syrian, Gregory abu'l-Faraj (Bar Hebraeus) and the anonymous Coptic author of a history of the patriarchs of Alexandria, which deals with the fifth crusade.

The contemporary Arabic literature on the crusades is of the greatest importance. Ibn al-Qalanisi's *Continuation of the History of Damascus* (from 1056), written between 1140 and 1160, is of high value and was used by most later Arab writers. The 11th-century Usamah ibn Munqidh's *Instruction by Examples* is a delightful set of personal memoirs. The *Complete Book of Chronicles* of the historian Ibn al-Athir (fl. early 13th century) is well documented and excellent, but his history of the atabegs of Aleppo is of less value. Sibti ibn al-Jawzi's *Mirror of the Times* is a universal history down to 1256. Kamal al-Din's *Cream of the History of Aleppo* is excellent on the Zangids, and Abu-Shamah's *Book of Two Gardens* is a prime source for Nureddin and Saladin. On Saladin, however, the best biography is that by Baha-al-Din. General information on the Arabs is provided by the biographical dictionary of Ibn Khallikan and in the historical work of Abulfiida. Al-Maqrizi's *Sermons and Learning by Example* deals with the crusade of Louis IX. Badr-al-Din al-Aini (d. 1451), in his *Collar of Pearls*, gives an account of the Mameluke sultans, as does Ibn Taghri-Birdi (1411–69) in *The Brilliant Stars regarding the Kings of Egypt and Cairo*. Finally there is the universal history of Ibn Khaldun, one of the greatest of all medieval historians. See also references under "Crusades" in the Index volume.

**BIBLIOGRAPHY.**—*Sources:* The principal collections of narrative sources on the crusades are the *Gesta Dei per Francos*, ed. by J. Bongars, 2 vol. (1611); and the *Recueil des historiens des croisades*, ed. by the Académie des Inscriptions et Belles-Lettres, 16 vol. (1841–1906), which has separate series on Armenian, Greek, Latin and Arabic material and on the *Assises*. There is also, for the fifth crusade, the *Scriptores minores Quinti Sacri Belli*, ed. by R. Röhrich (1879). Important collections of documents are R. Röhrich (ed.), *Regesta regni Hierosolymitani* (1893, with supplement, 1904); H. Hagenmeyer (ed.), *Die Kreuzzugsbriefe aus den Jahren 1088–1100* (1901). See also E. de Rozière, *Cartulaire de l'Eglise du Saint Sépulchre de Jérusalem*.

salem (1849); the cartularies of the Templars and of the Order of St. John of Jerusalem, and the collections of papal registers. For a complete discussion of the sources see C. Cahen, *La Syrie du Nord* (1940).

**Modern Studies:** Suggested bibliographical studies are A. Potthast, *Bibliotheca historica mediæ ævi*, 2 vol. (1896); A. Molinier, *Les Sources de l'histoire de France*, 6 vol. (1901-06), II, Part I, III, Part I; L. J. Paetow (ed.), *Guide to the Study of Medieval History*, rev. (1931); and H. E. Mayer, *Bibliographie zur Geschichte der Kreuzzüge* (1960). General histories are R. Röhricht, *Geschichte des Königreichs Jerusalem* (1898); L. Bréhier, *L'Église et l'Orient au moyen âge: les croisades*, 5th ed. (1928); R. Grousset, *Histoire des croisades*, 3 vol. (1934-36); J. Richard, *Le Royaume latin de Jérusalem* (1953); S. Runciman, *A History of the Crusades*, 3 vol. (1951-54); K. M. Setton (ed.), *A History of the Crusades* (1955 et seq.); and A. Waas, *Geschichte der Kreuzzüge*, 2 vol. (1956). C. Cahen, *La Syrie du Nord* (1940), is indispensable for northern Syria. W. B. Stevenson, *The Crusaders in the East* (1907), pays particular attention to Muslim sources. A history of the later period is A. S. Atiya, *The Crusade in the Later Middle Ages* (1938). H. Lamb, *The Crusades: Iron Men and Saints* (1930), is a popular work based upon the sources.

For the Jerusalem patriarchate see J. Hansen, *Das Problem eines Kirchenstaates in Jerusalem* (1928). For social customs in the Frankish states see H. Prutz, *Kulturgeschichte der Kreuzzüge* (1883); O. Henne am Rhy, *Kulturgeschichte der Kreuzzüge* (1894); D. C. Munro, *Kingdom of the Crusaders* (1935). For manorial customs see Helen G. Preston, *Rural Conditions in the Kingdom of Jerusalem* (1903). For feudal customs see M. Grandclaude, *Étude critique sur les livres des Assises de Jérusalem* (1923); D. Hayek, *Le Droit franc en Syrie pendant les croisades* (1925); J. L. LaMonte, *Feudal Monarchy in the Latin Kingdom of Jerusalem* (1932); J. Prawer, "La Noblesse et le régime féodal du royaume latin de Jérusalem," *Moyen Age* (1959). For the commercial affairs of the Latin states see W. Heyd, *Histoire du commerce du Levant au moyen âge*, trans. by F. Raynaud, 2 vol. (1885-86); E. H. Byrnn, "The Genoese Colonies in Syria," *The Crusades and Other Historical Essays Presented to Dana C. Munro by his Former Students*, ed. by L. J. Paetow (1928). For the crusaders' castles and architecture see C. Enlart, *Les Monuments des croisades dans le royaume de Jérusalem*, 4 vol. (1925-28); P. Deschamps, *Les Châteaux des croisades en Terre Sainte*, 2 vol. (1934-39); R. Fedden and J. Thompson, *Crusader Castles* (1957); and for military tactics as well, R. C. Small, *Crusading Warfare* (1956). Regarding the chansons which grew out of the crusades see J. Bédier, *Les Chansons de croisade* (1909); and A. Hatem, *Les Poèmes épiques des croisades* (1932).

See also general histories of the Byzantine empire; of medieval Syria and Palestine; and of the Templars, the Order of the Hospital of St. John of Jerusalem and of the Teutonic Order. The bibliographies to the separate biographical articles in this encyclopaedia on the individual crusaders and their opponents should also be consulted. (H. S. F.)

**CRUSHING AND GRINDING MACHINES.** Crushing and grinding (comminution) refer to the size reduction of rocks and other materials; size reduction is generally accomplished by pressure, impact or attrition, or by combinations of these. Crushers are used when the feed (material to be processed) is coarse; grinding mills, when the feed is relatively fine. Crushing and grinding operations are frequently conducted in a series of stages utilizing several types of machines. Operations are often classified as "coarse," "intermediate" and "fine," depending on the size of particles produced.

The term "pulverizing" is applied to some fine-grinding operations, and the term "disintegration" is often used in the case of size reduction of soft or loosely bonded materials.

Most crushers operate dry, that is, without the addition of water, the end product being discharged by gravity or the movement of the crushing elements. Many grinding mills can be operated either dry or wet, with the water or air assisting in the discharge of the end product. When a series of crushing or grinding machines are used it is common practice to classify the end product of each machine into at least two fractions (by screening, or settling in water or air), and return the oversize to the machine. This is called a "closed circuit" operation.

**Types.**—*Jaw crushers* have two crushing plates (jaws), with one or both pivoted, and moving alternately toward or away from each other. Maximum size feed is about 80 in. in diameter and usual reduction ratios (ratio of feed size to product size) are about 3:1 to 5:1.

*Gyratory crushers* have an outer stationary face which is a vertical, truncated conical shell (concave) with the smaller diameter at the bottom. The inner movable face is a similar shell (crushing head) mounted on a spindle, with the smaller diameter at the top. The movement of the spindle causes the crushing head to gy-

rate, alternately moving toward and away from all the points on the circumference of the concave. Maximum size feed is about 80 in. and usual reduction ratios are about 3:1 to 5:1. A cone crusher is a modification of the gyratory crusher, and is specially adapted to fine crushing. Maximum feed size for cone crushers is about 12 in.; reduction ratios are about 3:1 to 10:1.

*Rolls* can be classified as sledging rolls or crushing rolls. In both, the moving elements are cylindrical steel rolls rotating in a horizontal position.

A sledging roll, used for coarse crushing of relatively soft material, may consist of one roll with projecting teeth or knobs and a stationary breaker plate, or it may consist of two rolls driven toward each other at the top. Crushing rolls consist of two cylinders driven toward each other at the top where the feed is introduced.

The maximum feed size for sledging rolls is about 40 in., and for crushing rolls about 3 in. The usual reduction ratios are about 3:1 to 7:1.

*Hammer mills* are made in a number of different forms but consist essentially of a revolving shaft with rigid or swinging hammers (beaters). The hammers may be bars, special shapes or rings. The shaft and moving elements run in a housing which contains stationary plates or liners. A screen or grating may enclose the rotor to regulate the discharge size of the product. The grinding action results from impact of the hammers on the feed material. A multiple cage-mill is a modification, and consists of two cylindrical cages revolving in opposite directions inside of each other. Because of severe wear, hammer mills are normally limited to soft or friable materials. Some types are capable of reducing 10- to 30-in. material to less than 1 in.; other types are designed to reduce 0.5-in. feed to finer than 0.003 in.

*Tumbling mills* include rod, ball, pebble, tube, and compartment mills. These are all hollow horizontal rotating cylinders which contain grinding media such as steel balls, pebbles, steel rods, or even large pieces of rock. The material to be ground is usually fed at the centre of one end of the cylinder and discharged at the other end. The cascading and rolling action of the grinding medium results in the size reduction. A pebble mill with a length greater than two times the diameter usually is called a tube mill. A compartment mill is a tube mill divided into compartments along its length and frequently has an external means for trans-

FIG. 2.—BALL MILL

ferring the discharge from one compartment to another. A cascade type mill has a diameter several times greater than its length, and normally uses large pieces of the feed material as the grinding medium. A modification of the tumbling mill is the conical mill which has a conical section on one or both ends of the cylindrical section. Another modification is the vibrating mill wherein an oscillating or vibrating motion is imparted to the shell. Tumbling mills range from 1 to 14 ft. in diameter, and even larger in the case of cascade mills. Although cascade mills require coarse feed as large as 24 in. in diameter, most tumbling mills will not handle material coarser than 1½ in. Tumbling mills grind to 0.003 in. or finer.

*Ring-roller mills* consist of rollers mounted on vertical shafts and driven in a manner that causes the rollers to revolve around the inside of a die (grinding ring). In certain types, the grinding ring revolves around the rollers; in still another type, a single row of balls revolves between a stationary and a rotating ring, similar to ball bearings in a race. Feed and produce sizes are in the same range as for tumbling mills.

*Disk mills*, sometimes called attrition mills, consist of two disks or grinding plates, one or both of which rotate in a vertical or horizontal plane, usually at high speeds. The feed is introduced between the plates near their centres and is ground as it progresses to the periphery of the disks. A modification, using cylindrical stones instead of steel disks, is a buhrstone mill, often used for grinding cereals, grains and paints.

Disk mills are used for pulverizing, tearing and shredding. One-quarter inch is about the maximum size of feed, and produce size for different materials ranges from about 0.03 to 0.0004 in.

*Fluid energy mills*, also referred to as jet mills, have no moving parts within the grinding chamber. The energy for grinding is achieved by the introduction of compressed air or superheated steam, into the grinding chamber through small nozzles, resulting in high velocities inside the mill. The feed material is introduced to the grinding chamber through the nozzles or more commonly through a separate opening in the grinding chamber. Attrition and impact of particles upon each other are the major causes of size reduction.

Maximum feed size ranges from ½ in. to 0.005 in. Minimum product size is about 0.0001 in.

*Miscellaneous types of crushing and grinding equipment* include: pan crushers in which one or more crushing wheels (mullers) travel around a circular pan; stamp mills, having a pestle with a steel head, which is driven vertically downward against a die; rotary crushers with a toothed cone driven within a cylindrical housing having inward projecting teeth; arrastras which consist of heavy stones dragged around a stone-lined circular pit (see AMALGAMATION).

See also ORE DRESSING; CROP-PROCESSING MACHINERY; MACHINE TOOLS. (O. F. T.)

**CRUSTACEA**, a very large class of invertebrate animals of the phylum Arthropoda. Crusta-

ceans include the crabs, lobsters, crayfish, prawns, shrimps, sand hoppers, wood lice, barnacles, water fleas and a vast multitude of less familiar forms that are not distinguished by any popular names. They are distinguished from the members of the other classes of arthropods by being generally of aquatic habits, breathing by gills or by the general surface of the body and having two pairs of antennalike appendages in front of the mouth and at least three pairs of postoral limbs acting as jaws. There is so much diversity, both of structure and of habits, within the class, that it is all but impossible to give a brief definition that would apply to all its members.

## INTRODUCTION

It would not be altogether misleading to describe the Crustacea as the "insects of the sea." In the great oceans and in the narrow seas their teeming multitudes, the "things creeping innumerable" of the Psalmist, play a part not unlike that taken by the true insects in the life of the land. In fresh waters, where they have to meet with the competition of insects, they are hardly less abundant and there is scarcely a ditch or pond that does not harbour at least some of the more minute forms. On land they are less common, but the wood lice or pill bugs of our gardens and the land crabs of tropical regions have solved the problem of adaptation to a non-aquatic life.

The most familiar crustaceans are the larger crabs and lobsters that are used as food by man, but the part that these play in the economy of nature is small compared with that of the amphipods

FROM T. I. STORER AND R. L. USINGER, "GENERAL ZOOLOGY", 1937, REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., INC.

FIG. 1.—REPRESENTATIVE SALT- AND FRESH-WATER CRUSTACEANS (NOT DRAWN TO SCALE)

nearly every trace not only of crustacean but even of arthropodous structure; an example is *Sacculina*, parasitic in crabs.

**General Structure of Limbs.**—Amid the great variety of forms assumed by crustacean appendages, it is possible to trace, more or less plainly, the modifications of a fundamental type consisting of a peduncle, the protopodite (or sympodite), bearing two branches, the endopodite and exopodite. This simple biramous, or two-branched, form is shown in the swimming feet of Copepoda, the cirri of Cirripedia and the abdominal limbs of Malacostraca, and it is also found in the earliest and most primitive type of larva known as the nauplius. The protopodite may have, on its inner and outer margins, additional lobes or processes, known as endites and exites respectively. Some of the exites often function as gills, and the endites of appendages near the mouth frequently form jaw processes, assisting in mastication and known as gnathobases. In the flattened leaflike limbs characteristic of the Branchiopoda the endites and exites are so developed that the biramous form of the limb is obscured. It has been supposed that this form of limb, the phyllopodium, represents the primitive type from which the biramous type has been derived. The recurrence of the biramous type, however, in the most diverse forms of Crustacea and in the simplest larvae, and the evidence of the remarkable fossil branchiopod *Lepidocaris*, all indicate that it represents the fundamental plan of the crustacean limb.

In many Crustacea the paired eyes are borne on stalks that are movably articulated with the head and may be divided into two or three segments. The view has been held that these eyestalks are really limbs, homologous with the other appendages. The evidence of embryology, however, is decidedly against this view. The stalks appear late in the course of development, after many of the limbs of the trunk are fully formed, and the eyes, at their first appearance, are sessile on the sides of the head and only later become stalked. The most important evidence in favour of the appendicular nature of the eyestalks is found in the fact that when the eyestalk is removed from a living lobster or prawn, a many-jointed appendage like the flagellum of an antenna may grow in its place.

It is open to question, however, how far the evidence from such heteromorphic regeneration (see REGENERATION) can be regarded as conclusive on points of homology.

**Specialization of Limbs.**—The antennules (or first antennae) are generally regarded as true appendages, although they differ from all the other appendages in that they are always innervated from the brain (or preoral ganglia) and are uniramous in the earli-

FIG. 5.—MOUTH PARTS OF CRUSTACEA

Copepod (*Calanus*): (A) mandible with biramous palp. Lobster (*Homarus*): (B) mandible with reduced and unbranched palp; (C) maxillula; (D) maxilla; (E) third maxilliped

est larvae and in the adults of all subclasses except the Malacostraca, where they are biramous or sometimes triramous. It is unlikely that the two branches of the biramous type (seen, for instance, in the antennules of the lobster) correspond to the endopodite and exopodite of the other limbs.

The antennae (or second antennae) are of special interest because of the clear evidence that, although preoral in position in all adult Crustacea, they were originally postoral appendages. In the nauplius larva they lie at the sides of the mouth and their basal portion carries a hooklike process that assists the similar processes of the mandibles in pushing food into the mouth.

In most Crustacea the antennules are purely sensory in function and carry numerous olfactory hairs. They are used as swimming organs in many larvae and some adults, and sometimes, in the male, they form clasping organs for holding the female. In the Cirripedia the antennules of the larvae carry the openings of the cement glands and become, in the adult, involved in the attachment of the animal to its support.

The antennae are frequently swimming organs, but they may assume other functions as organs of attachment in parasites, as creeping legs or as male claspers. In the Malacostraca they are chiefly sensory, the endopodite forming a long many-jointed lash (flagellum), whereas the exopodite is often a flattened plate, probably used as a balancer in swimming.

The mandibles, like the antennae, have, in the nauplius the form of biramous swimming limbs, with a jaw lobe on the protopodite. This form is retained in some adult Copepoda and Ostracoda. In most cases, however, the palp loses its exopodite and it often disappears altogether, and the basal lobe becomes a powerful jaw with the edge variously armed with teeth and spines. In blood-sucking parasites the mandibles are often piercing stylets enclosed in a tubular proboscis formed by the upper and lower lips.

The maxillulae and maxillae, or, as they are often called, first and second maxillae, are nearly always flattened leaflike appendages with gnathobasic lobes or endites borne by the protopodite. The endopodite, when present, forms a palp of one or a few segments, and exites may also be present.

The limbs behind the head region show little differentiation among themselves in the Branchiopoda, Cirripedia and many Copepoda. It is characteristic of the Malacostraca that the limbs of the trunk are divided into two sharply defined series (tagmata): eight corresponding to the thoracic and six to the abdominal region. The thoracic series have the endopodites converted, for the most part, into more or less efficient walking legs, whereas the exopodites are formed into swimming organs or disappear. It is usual for

AFTER HERRICK

FIG. 4.—LOBSTER (*HOMARUS*): (A) ANTENNULE; (B) DORSAL VIEW OF ANTENNA; (C) VENTRAL VIEW OF BASAL PORTION OF ANTENNA (FLAGELLUM CUT OFF)

*Stenorhynchus seticornis*, spider crab, so-called because of its spidery walking legs. This species is commonly found at moderate depths along the north Atlantic coasts

Marine cladoceran or water flea, one of the smallest living crustaceans. Cladocerans convert tinier aquatic and marine organisms into food for higher marine animals

Closed shells of acorn barnacles (*Balanus perforatus*), sessile crustaceans which live in the intertidal zone on rocks, pilings and ships. Extremely modified in form, adult barnacles bear little external resemblance to other crustaceans. See below

Red krill (*Euphausia*), a planktonic, phosphorescent shrimp that inhabits the open sea and provides the principal food for the whalebone (baleen) whale

Open shell of an acorn barnacle (*Balanus nubilus*) with extended cirri, the fine hairs of which strain plankton from the water during high tide. The shell closes during low tide to prevent loss of moisture. See above

Ghost crab (*Ocypode arenaria*), a land crab found on beaches from Long Island, N.Y., to Rio de Janeiro, Brazil. Ghost crabs are active at night; during the day they burrow into the sand above the high-water mark. They are about 2 in. across with a leg span of as much as 8 in.

## MARINE CRUSTACEANS

Blue crab, an edible species (*Callinectes sapidus*) found along the east coast of the U.S. from Cape Cod to Louisiana, is valued by the fishing industry. Fully grown males may attain a shell width of more than 8 in.

*Temora longicornis*, a marine copepod, microscopic in size. Among the most numerous animals in the sea, copepods play an important role in the economy of the sea, ranking first as food for other marine animals.

Scud (*Gammarus*), an amphipod found in the fresh waters of the U.S. Less than an inch long, it is shown here on its side, its natural position for swimming.

Microscopic female *Cyclops*, a fresh-water copepod, carrying egg sacs attached to each side of its body. Copepods are colourless and transparent; the colour here results from the use of special illumination to reveal the physical details of the specimen.

Common shrimp (*Penaeus setiferus*), commercially one of the most important species on the south Atlantic and Gulf coasts of the U.S. At one year males are about 6 in. long, females 6½ to 7 in. Commercially fished shrimp are about 3½ in. long.

Burrowing crayfish (*Cambarus diogenes*) emerging from the mud chimney that surrounds its burrow. Crayfish are found in and around fresh waters of all continental land masses except Africa.

### MARINE AND FRESH-WATER CRUSTACEANS

Female copepod (*Torycaeus anglicus*) with egg sac, a marine copepod common in the English channel. Many copepods are parasitic; the mouth structure of this species indicates that it is probably semiparasitic in habit

Spider crab (*Maia squinado*) common to the littoral zone of the Atlantic and Mediterranean. Spider crabs affect a protective camouflage by covering their bodies with seaweed and other organic materials from their surroundings

Colony of marine copepods (*Pseudocalanus elongatus*). Copepods live on diatoms and other microscopic life and form one of the most important constituents of the plankton

Aquatic sow bug (*Asellus*), a fresh-water isopod about 1 in. long. It is found on the muddy bottom of shallow waters, where it acts as a scavenger, feeding on animal and vegetable debris of all kinds

Hermit crab (*Coenobita rugosa*), a land crab of the east African coasts. Lacking a hard-shell covering of its own, the hermit crab lives in the empty shell of a gastropod mollusk

"Mantis shrimp" (*Pseudosquilla bigelowi*), a predatory marine crustacean found in shallow waters of all warmer seas, where it burrows into the sand or lurks in crevices, waiting for a small fish to come within reach of its jackknife claw

#### MARINE AND FRESH-WATER CRUSTACEANS

Gooseneck barnacles (*Lepas anatifera*), found along the seashore attached to driftwood. The main body of the animal is enclosed in calcareous plates that hang from a stalk. These barnacles obtain food in the same way as acorn barnacles. See Plate I

Mature female *Daphnia*, the most common fresh-water cladoceran or water flea. The transparency of cladocerans permits the study of internal structure, unborn young can be seen in the dorsal brood pouch of this specimen

Sand hopper or beach flea (*Orchestoidea californiana*), a land amphipod ranging in size from  $\frac{1}{2}$  in. to  $2\frac{1}{2}$  in. It lives on ocean beaches, hiding in burrows in the sand above the high-water mark and searching for food under piles of rotting seaweed

Pill bug (*Ligia pallasii*), an isopod that inhabits the rocky seacoast from Alaska to California. It feeds in the intertidal zone when the tide is out, but returns to land when the tide comes in

American lobster (*Homarus americanus*), an edible crustacean commercially important in the U.S. Fished from rocky bottoms of shallow waters from Labrador to North Carolina, an average-sized lobster in a catch is about 9 in. in total length

Barber-shop or coral shrimp (*Stenopus hispidus*), a bizarre-looking shrimp that scavenges for food on coral reefs and wharf pilings throughout the West Indies

#### MARINE AND FRESH-WATER CRUSTACEANS

one or more of the anterior pairs to be modified as "foot-jaws" or maxillipeds. The abdominal limbs are usually biramous swimming structures, the last pair being large and flattened and forming with the telson a lamellar "tail-fan."

**Gills.**—In many of the smaller Crustacea no special gills are present and respiration is carried on by the general surface of the body and limbs. When gills are present they are generally formed by some of the exites near the base of the limb, which are flattened, thin-walled and permeated by a network of blood channels. In the Decapoda the gills are inserted, in three series, at or near the bases of the thoracic limbs, and lie within a pair of branchial chambers covered by the carapace.

Adaptations for aerial respiration are found in those Crustacea that have taken to terrestrial life. In the land crabs (of several different families) the branchial chambers are enlarged and serve as lungs, the lining membrane being richly supplied with blood vessels. In some of the terrestrial Isopoda, or wood lice, the abdominal appendages contain tufts of branching tubules filled with air, like the tracheae of insects and other terrestrial Arthropoda.

#### INTERNAL FEATURES

**Digestive System.**—In almost all Crustaceae the food canal runs straight through the body, except in front where it curves downward to the ventrally placed mouth. In a few cases its course is sinuous or twisted and in one or two instances (Cladocera, Cumacea) it is actually coiled upon itself. As in other Arthropoda, the digestive system consists of three divisions, the fore-, mid- and hind-gut, the first and last being lined by an inturning of the chitinous cuticle. In the Malacostraca, the fore-gut is dilated to form a so-called stomach, furnished internally with ridges armed with spines and hairs forming a straining apparatus. In the Decapoda this apparatus reaches its greatest complexity, forming a gastric mill in which three teeth connected with a system of articulated ossicles are moved by special muscles so as to pulverize the food that is passed into the stomach.

The mid-gut is essentially the digestive and absorptive region of the alimentary canal and its surface is, in nearly all Crustacea, increased by pouchlike or tubular outgrowths that not only serve as glands for secretion of the digestive juices but aid in the absorption of the digested food. In the Decapoda these outgrowths form a massive digestive gland of "liver."

In some decapods, as the crayfish, the mid-gut is very short, nearly the whole length of the food canal being formed by the fore- and hind-guts. In a few highly modified parasites the alimentary canal is vestigial or absent throughout life as in the Rhizocephala (see BARNACLE).

**Circulatory System.**—As in the other Arthropoda, the circulatory system in Crustacea is largely lacunar, the blood flowing in sinuses or channels lacking definite walls. The heart is of the usual arthropodous type, lying in a pericardial blood sinus with which it communicates by valvular openings, or ostia. In most Branchiopoda and in some Malacostraca the heart retains more or less completely the primitive form of a long tube, extending throughout the greater part of the length of the body and having a pair of ostia in each somite. In most Crustacea, however, the heart is shortened and gives off one or more main arteries that carry the blood for some distance to pour into the blood spaces of the body. In many of the smaller Crustacea there is no heart, and it is impossible to speak of a circulation in the proper sense of the

word, the blood being merely driven hither and thither by the movements of the body and limbs and of the alimentary canal.

**Excretory System.**—The most important excretory organs of the Crustacea are two pairs of glands lying at the base of the antennae and of the maxillae respectively. The two are rarely functional together, although one may replace the other in the course of development. In the adult it is sometimes the antennal, sometimes the maxillary gland that persists. The structure of both glands is essentially the same, and they are to be regarded as the survivors of a primitive series of segmentally arranged nephridia. Each gland consists of a thin-walled end sac which developmental studies show to be a vestigial portion of the coelom, communicating with the exterior by a convoluted duct, part of which has glandular walls. Probably in most cases the greater part of this duct arises from mesoderm and only a short terminal part from ectoderm, but it is stated that in some cases the whole duct is ectodermic.

In the Decapoda the antennal gland is largely developed and is known as the "green gland." The external part of the duct is often dilated into a bladder, and may sometimes send out pouches, or diverticula, forming a system of sinuses ramifying through the body.

Other excretory organs have been described in certain Crustacea, consisting of groups of mesodermal cells in various parts of the body within which the excretory products are stored up instead of being expelled. Possibly some of these are vestiges of segmentally arranged nephridia.

**Nervous System.**—The central nervous system is constructed on the same general plan as in other Arthropoda, consisting of a supra-esophageal ganglionic mass or brain, united by circumesophageal connectives with a double ventral chain of segmentally arranged ganglia. In the primitive Branchiopoda the ventral chain retains the ladderlike arrangement found in some annelids, the two halves being widely separated and the pairs of ganglia connected together across the middle line by double transverse commissures. In the other groups the two halves of the chain are more or less coalesced, and, in addition, the ganglia tend to draw together in a longitudinal direction and to fuse, ultimately, into a single mass representing the whole of the ventral chain. This is seen, for example, in the true crabs (Brachyura) among the Decapoda.

The brain, or supra-esophageal ganglion, shows various degrees of complexity. In the Branchiopoda it contains two pairs of ganglionic centres giving origin, respectively, to the optic and the antennular nerves. The centres for the antennal nerves form ganglionic swellings on the esophageal connectives. In the higher forms these centres have moved forward to become incorporated in the brain, but the fibres that unite them still run backward to form a transverse commissure behind the esophagus. This is of importance as showing that the antennae were originally postoral

AFTER HERRICK

FIG. 8.—LONGITUDINAL SECTION OF FEMALE LOBSTER (HOMARUS), RIGHT HALF SHOWN; HEAD IS SLIGHTLY ENLARGED TO SHOW NERVOUS SYSTEM

limbs. In the higher Decapoda, additional centres are developed in the brain and its structure becomes very complex. A system of visceral nerves and ganglia associated with the alimentary canal and the heart is well developed in the Decapoda.

**Eyes.**—The eyes of Crustacea are of two kinds, the unpaired median, or nauplius, eye, and the paired compound eyes. The median eye is generally present in the earliest larval stages (nauplius), and in some instances, as in the Copepoda, it forms the sole organ of vision. It may persist along with the paired eyes, as in the Branchiopoda, or it may become vestigial or disappear in the adult, as in most Malacostraca. It consists typically of three cup-shaped masses of pigment, the cavity of each cup being filled with columnar retinal cells connected at their outer ends with nerve fibres from the brain.

The compound eyes are very similar in the details of their structure to those of insects, consisting of a varying number of visual elements or ommatidia separated by pigment sheaths. Each sheath terminates in a crystalline body covered by the transparent external cuticle that forms the cornea. In most cases the cornea is divided into lenslike facets corresponding to the underlying ommatidia.

**Other Sense Organs.**—As in other Arthropoda, the hairs, or setae, on the surface of the body are important organs of sense and are variously modified for special functions. Many, perhaps all, of them are organs of the sense of touch. Those setae that are feathered or provided with secondary barbs respond to movements or vibrations in the surrounding water and some of them are thought to have an auditory function. Organs formerly regarded as auditory, but now known to be connected with the maintenance of equilibrium of the body, are the statocysts found in various positions in different Crustacea, notably at the base of the antennules in most decapods. Statocysts are open or closed vesicles having sensory hairs on their inner surface and containing one or more statoliths. The latter may be grains of sand introduced from the exterior.

Another type of sensory setae is associated with the sense of smell, or rather, perhaps the chemical sense. These are bluntly pointed filaments in which the cuticle is extremely delicate. They are found chiefly on the antennules, and are often especially developed in the males, in which they are thought to act as sensitive devices for detecting the presence of females.

**Glands.**—The most important glandular structures in Crustacea (in addition to the digestive and excretory glands already mentioned) are various types of dermal glands that occur on the surface of the body and limbs. Some of these in the region of the mouth or on the walls of the esophagus have been regarded as salivary, but in some cases are now known to produce a mucous secretion that serves to entangle minute food particles. In some Amphipoda the secretion of glands on the surface of the body and limbs is used in the construction of protective cases in which the animals live. In some fresh-water Copepoda the dermal glands secrete a gelatinous envelope enabling the animals to resist desiccation. The greatly developed cement glands of the Cirripedia, which serve to attach the animals to their support, probably also belong to the category of dermal glands. More intensively studied are the very important sinus glands. Often called the eyestalk glands because of their location in the higher Crustacea, they are a part of a neurosecretory system whose hormones control colour change, colour pattern, molting, development of the eggs within the ovary and perhaps other nervous and physiological reactions. Chromatophoretropins and perhaps other hormonal substances have been extracted from parts of the central nervous system, the brain and thoracic cord in particular. This may well be the source of such hormones in the sessile-eyed crustaceans, which lack sinus glands.

**Phosphorescent Organs.**—Like many other marine animals certain Crustacea, belonging to very diverse groups (Ostracoda, Copepoda, Mysidacea, Euphausiacea, Decapoda), possess the power of emitting light. All of them are inhabitants of the deep sea or of the surface waters of the ocean. No fresh-water Crustacea are phosphorescent. The organs concerned in the production of light are curiously varied. In the Ostracoda and Copepoda certain dermal glands produce a luminous secretion. In some Mysida-

cea and Decapoda the secretion of the excretory organs (maxillary or antennal glands) is luminous. In the Euphausiacea and certain Decapoda the light-producing organs found on the body and limbs are complex structures provided with a reflector and a condensing lens and movable by special muscles so as to vary the direction of the emitted beam. The part that phosphorescence plays in the life of the animals can only be conjectured. In some instances it may serve to attract prey; in others it may help individuals of the same species to keep together in a shoal or to find their mates. The clouds of luminous secretion thrown out by some species may serve to baffle pursuers as does the cloud of ink thrown out by a cuttlefish. The elaborate "searchlights" may illuminate objects within the range of vision. But even conjecture seems at a loss when it is found that certain deep-sea prawns have complex light organs placed so as to illuminate the interior of the gill chambers.

## REPRODUCTION AND DEVELOPMENT

**Reproductive System.**—In the great majority of Crustacea the sexes are separate, but in the Cirripedia and in some parasitic Isopoda hermaphroditism is the rule, and isolated instances occur in other groups, especially among Decapoda. Parthenogenesis is common in Branchiopoda and Ostracoda and occurs in at least one genus of terrestrial Isopoda.

Where the sexes are separate, sexual dimorphism is often striking. The males are often provided with clasping organs for holding the female, and these may be formed by modification of almost any of the appendages—antennules, antennae, thoracic limbs or even some of the mouth parts. Some of the appendages in the region of the genital openings may be modified for the purpose of transferring the sperm to the female, as, for instance, the first and second abdominal appendages in the Decapoda.

In the higher Decapoda the male is often larger than the female but in other groups the reverse is more frequently the case. In some parasitic Copepoda and Isopoda the disparity in size is carried to an extreme degree, and the minute male is attached, like a parasite, to the enormously larger female.

In the Cirripedia some very aberrant types of sexual relationship exist. Whereas the great majority are hermaphrodites capable of both cross- and self-fertilization, it was discovered by Darwin that, in certain species, minute degenerated males exist, attached to the ordinary individuals. Since these dwarf males pair, not with females but with hermaphrodites, Darwin termed them "complemental" males. In other species the large individuals have become purely female by atrophy of the male organs and are entirely dependent on the dwarf males for fertilization.

Nearly all Crustacea carry the eggs in some way or other after extrusion. They are retained between the valves of the carapace in some Branchiopoda and Ostracoda, or within the mantle cavity in Cirripedia. Among the Malacostraca the Peracarida have a brood pouch formed by overlapping plates attached to the bases of some of the thoracic legs. In most Decapoda the eggs are carried on the abdominal appendages of the female. In a few cases the developing embryos are nourished by a special secretion while in the brood chamber (Cladocera, terrestrial Isopoda).

**Larval Stages.**—The majority of Crustacea are hatched from the egg in a form differing more or less from that of the adult and pass through a series of free-swimming larval stages. There are many instances, however, in which the metamorphosis is suppressed and the newly-hatched young resemble the parent in general structure.

In those Crustacea in which the series of larval stages is most complete the earliest stage is the nauplius already mentioned. In the usual form, this has an oval unsegmented body and three pairs of limbs corresponding to the antennules, antennae and mandibles of the adult. The antennules are simple, the others each two-branched; all three pairs are used in swimming. The antennae and mandibles have a spinelike process at the base and share the function of seizing food and pushing it into the mouth. The mouth is overhung by a large upper lip, or labrum. The paired eyes are as yet wanting, but the unpaired eye is usually conspicuous.

A nauplius larva differing only in details from that just described is found in most of the Branchiopoda. Copepoda and Cirripedia

FIG. 7.—COMMON LARVAL FORMS

Copepod (*Cyclops*): (A) nauplius. Branchiopod (*Apus*): (B) nauplius. Crab (*Cancer*): (C) anterior view of zoea; (D) longitudinal view of zoea

and, in a more modified form, in some Ostracoda. Among the Malacostraca the nauplius is found in the Euphausiacea and some of the most primitive Decapoda. In many of the Crustacea that hatch at a later stage there is more or less clear evidence of a nauplius stage in the embryonic development. It seems certain, therefore, that the possession of a nauplius larva must be regarded as a very primitive character of the Crustacea.

As development proceeds, the body of the nauplius elongates and its posterior part becomes segmented, new somites being added at successive molts from a formative zone in front of the telsonic region. The appendages, which appear as buds on the ventral surface of the somites, become differentiated, like the somites that bear them, in regular order from front to rear. With the elongation of the body, its dorsal covering begins to project behind as a shell fold, the beginning of the carapace. The paired eyes appear under the cuticle at the sides of the head but only become stalked at a comparatively late stage.

The course of development here outlined, in which the somites and appendages appear in regular order, agrees so well with that observed in the typical Annelida that it must be regarded as the most primitive. It is most closely followed in some Branchiopoda and Copepoda.

In most Crustacea, however, this primitive scheme is more or less modified. The earlier stages may be passed through within the egg; thus the larva, on hatching, has reached a stage more advanced than the nauplius. The gradual appearance of somites and appendages may be accelerated so that comparatively great advances take place at a single molt, or individual somites or pairs of appendages may appear in advance of their neighbours, disturbing the regular order of succession. This last type of modification is especially evident in the Malacostraca in which it leads to the very peculiar larva known as the zoea. In the usual form of zoea, found in the true crabs, the posterior five or six thoracic somites are delayed in development. These somites are still represented by a short unsegmented region of the body at a stage when the abdominal somites behind them are fully formed and even carry appendages.

Most of the larval forms swim freely at the surface of the sea and show adaptations to this pelagic habit of life. Various spines and processes from the surface of the body are often developed and are probably less important as defensive organs than as aids to flotation. Also considered as aids to flotation are the greatly developed carapace of stomatopod larvae and the extreme flattening of the body in the membranous phyllosoma larvae of the spiny lobsters and their allies.

Complete suppression of metamorphosis is found in the fresh-water crayfish and the river crabs, but is by no means universal among fresh-water Crustacea. On the other hand, a few marine

crabs are known to be hatched in a form differing little from that of the adult.

## PHYLOGENY AND EVOLUTION

Fossil remains of Crustacea are abundant in rock strata belonging to all the main divisions of the geological time-scale from the most ancient up to the most recent, but they disclose disappointingly little regarding the phylogeny of the class. This is partly due to the fact that many important forms must have escaped fossilization altogether owing to their small size and delicate structure. Very many of those actually preserved are known only from the carapace or shell, the limbs being absent or represented only by indecipherable fragments. The fortunate accident that has preserved with marvellous completeness the minute branchiopod *Lepidocaris* in the Old Red Sandstone of northwestern Europe is not likely to have been often repeated. *Lepidocaris*, however, is of recent date as compared with the varied fauna of Crustacea discovered by C. D. Walcott in the Middle Cambrian layers of the Canadian Rockies. There is reason to believe that many of the chief groups were already differentiated even before the beginning of the geological record. Shrimplike forms that can be definitely referred to the Malacostraca begin to appear in the Upper Devonian, and Mysidacea and Syncarida can be recognized in the Carboniferous, but it is not until true decapods appear in the Triassic that anything like a connected story can be made out.

In the dearth of evidence from palaeontology one is compelled to rely on the data afforded by comparative anatomy and embryology in attempting to reconstruct the course of evolution within the class. Conclusions reached in this way must of course remain more or less speculative so long as they cannot be checked by the results of palaeontology.

The earlier attempts to reconstruct the genealogical history of the Crustacea were based on the "theory of recapitulation," in this instance the assumption that the successive stages of the larval history, especially the nauplius and zoea, reproduced the actual structure of ancestral types. It is now generally agreed that this theory cannot be applied to the zoea, the characters of which must be due to secondary modification. As regards the nauplius, however, the constancy of its general structure in the most diverse groups of Crustacea strongly suggests that it is a very ancient type, and the view has been strongly advocated that the Crustacea must have arisen from an unsegmented naupliuslike ancestor. Yet resemblances between the more primitive Crustacea and annelid worms, in such characters

FIG. 8.—LIFE CYCLE OF A PARASITIC CRUSTACEA

Barnacle (*Sacculina*) that lives in crab: (A) nauplius (floating) larva; (B) cypris (free-swimming) larva; (C) degenerate sac-like adult (heavily stippled), with rootlike extensions, attached to underside of crab

as the structure of the nervous system and the mode of growth of the somites, can hardly be ignored, and it is reasonable to suppose that the Crustacea originated from some stock that already possessed these characters.

The hypothetical ancestral crustacean is thought to have resembled, in general form, some such branchiopod as *Apus*, with an elongated body composed of numerous similar somites and ending in a caudal fork; a carapace originating as a shell fold from the maxillary somite; the eyes probably stalked; the antennae and mandibles both biramous and armed with masticatory processes; and the limbs of the trunk all similar, biramous, with additional endites and exites, and probably all bearing gnathobases. It is to be noted that, except for the absence of a carapace fold and of eye-stalks, the trilobites (*q.v.*) are not very far removed from this primitive crustacean.

## CLASSIFICATION

The diversity of structure in the members of the class Crustacea is much greater than in any of the other classes of Arthropoda, and the scheme of classification that must be devised in order to ex-

press their affinities is correspondingly complex. Early in the 19th century P. A. Latreille divided the class into two main groups, Malacostraca and Entomostraca. The Malacostraca constituted a well-defined, natural subclass that is still recognized today. The Entomostraca, however, covered such a heterogeneous assemblage of Crustacea that it has ceased to be a definitive term, though it is still occasionally used to refer to the nonmalacostracan crustaceans generally. The Crustacea are presently classified into eight subclasses: the Malacostraca, which is divided into two series, Leptostraca and Eumalacostraca; and the seven subclasses of the nonmalacostracan crustaceans.

The following is a synopsis of the classification. Some further details will be found in the articles dealing with the subclasses.

#### Class Crustacea

- Subclass Cephalocarida (2 species)
- Subclass Branchiopoda (more than 800 species)
  - Orders Anostraca, Lipostraca (fossil only), Notostraca, Conchostraca and Cladocera
- Subclass Ostracoda (perhaps 2,000 species)
  - Orders Myodocopa, Cladocopa, Podocopa, Platycopa
- Subclass Mystacocarida (3 species)
- Subclass Copepoda (more than 5,000 species)
  - Orders Calanoida, Harpacticoida, Cyclopoida, Monstriloida, Caligoida, Lernaepodoida
- Subclass Branchiura (at least 75 species)
  - Order Arguloida
- Subclass Cirripedia (800 plus species)
  - Orders Thoracica, Acrothoracica, Ascothoracica, Apoda, Rhizocephala
- Subclass Malacostraca (over 18,000 species)
  - Series Leptostraca
    - Superorder Phyllocarida
      - Order Nebaliacea
  - Series Eumalacostraca
    - Superorder Syncarida
      - Orders Anaspidacea, Bathynellacea
    - Superorder Peracarida
      - Orders Thermosbaenacea\*, Spelaeogriphacea, Mysidacea, Cumacea, Tanaidacea, Isopoda, Amphipoda
    - Superorder Eucarida
      - Orders Euphausiacea, Decapoda
    - Superorder Hoplocarida
      - Order Stomatopoda

\*A superorder Pancarida has been urged recently for the Thermosbaenacea following the Syncarida, but its acceptance has been limited.

**CRUVEILHIER, JEAN** (1791–1874), French pathologist, born at Limoges on Feb. 9, 1791, first occupant of the chair of pathology after it was established at the University of Paris in 1836. He gave the first description of multiple sclerosis and left an early account of progressive muscular atrophy, but he erroneously supposed that pyemia (generalized blood poisoning accompanied by multiple abscesses) was always the result of phlebitis, which he referred to as an original coagulation of the blood. He even went to the extreme of asserting that phlebitis dominates all pathology. His name is still used as part of the medical names for congenital cirrhosis of the liver and stomach ulcers caused by excess acid. Cruveilhier died at Sussac on March 6, 1874. His chief works are *Anatomie descriptive* (1834–36); *Anatomie pathologique du corps humain* (1829–42), with many coloured plates; *Traité d'anatomie pathologique générale* (1849–64); *Anatomie du système nerveux de l'homme* (1845); *Traité d'anatomie descriptive* (1851).

**CRUZ, RAMÓN DE LA** (1731–1794), Spanish dramatist of spontaneously comic genius who excelled in short sketches (*sainetes*), was born on March 28, 1731, in Madrid, where he died on March 5, 1794. Some of his most popular sketches depict or tolerantly satirize Madrid life. Some treat slyly of topical pre-

occupations; some, with appropriate dialect or jargon, of regional or professional idiosyncrasies. Others, rivaling John Gay's *Beggar's Opera*, glorify back-alley scenes and characters, as a form of nonsense literature, or to parody the unpopular Augustan tragedy. Typical are *El prado por la noche* ("The Prado at night") and the "laughable" tragedy *Manolo* (1769). (I. L. Mc C.)

**CRUZ, SOR JUANA INÉS DE LA** (JUANA INÉS DE ASBAJE) (1651–1695), Mexican poet, scholar and nun, called Mexico's Tenth Muse and the Mexican Phoenix, was born on Nov. 12, 1651 (recent research sets her birth date three years earlier) in the village of San Miguel Nepantla, not far from Mexico City.

A precocious child, at three she learned to read; at eight she composed a *loa* (short dramatic poem) in honour of the Blessed Sacrament; at the same time she begged her parents to send her to the University of Mexico, but had to be content with reading her grandfather's books; at nine she went to live in Mexico City, where she studied Latin, mastering the language in 20 lessons.

The fame of her learning reached viceroy Mancera, who invited her to court, where she became very popular because of her wit, facility in writing poetry, beauty and magnetic personality. In an oral examination arranged by the viceroy, Juana Inés, who was then 17, astonished 40 professors with her knowledge.

In order to dedicate her life to learning, and perhaps influenced by a disappointment in love, Juana Inés entered the convent of San Jerónimo on Feb. 24, 1669. There she assembled a library of about 4,000 volumes, experimented in the sciences, wrote poems and religious and secular plays. Attempts were made, however, to curb her scholastic activities. The bishop of Puebla, under the pseudonym of Sor Filotea, admonished her to concentrate on religious studies. In her *Respuesta a Sor Filotea*, a long letter written March 1, 1691, she defended her desire for broad knowledge and her course of life. Two years later, however, she gave up all contact with the world, signed a confession with her own blood, sold her books, scientific and musical instruments, distributed the money to the poor and devoted her time exclusively to religious duties. She died on April 17, 1695, the victim of an epidemic, while nursing her sister nuns.

The three volumes of her works were printed in Spain; the first, *Inundación castálida* . . . appeared in Madrid in 1689; the second, *Segundo volumen de las obras de Sórora Juana Inés de la Cruz*, in Seville in 1692; and the third, *Fama y obras póstumas* . . . in Madrid in 1700. Several editions of the three volumes appeared during the 18th century. Other of her productions were printed separately. The influence of Góngora and Calderón is evident in some of her works. More important, however, is the subtlety, grace, fervour and versatility of her poetical compositions.

**CRUZ E SILVA, ANTÓNIO DINIS DA** (1731–1799), Portuguese poet chiefly remembered for a satirical poem, *O Hissope*, was born of humble parentage in Lisbon on July 4, 1731, and was educated at the University of Coimbra where he took his degree in law in 1753. He obtained judicial appointments in various towns, and in 1756 helped to found the literary society known as the *Arcádia Lusitana* which combated 17th-century extravagances and sought to resuscitate Portuguese poetry by urging closer adherence to Greek and Latin models. In 1776 he was sent as a judge to Rio de Janeiro where he died on Oct. 5, 1799. Like the other poets of his day, Cruz e Silva attempted many kinds of verse but his fame rests mainly on his witty satire, *O Hissope*, the best of the mock-heroic genre in Portugal, in eight cantos of blank verse. It was published posthumously in 1802, but written probably before 1773 and revised later. The theme is based on a quarrel between the bishop and the dean at Elvas.

**BIBLIOGRAPHY.**—Cruz e Silva's poems were published in 6 vol. (1807–

1817). A critical edition of the *Hísopo* by J. R. Coelho appeared in 1879 with an introductory study on the poet's life and writings. See also T. Braga, *A Arcádia Lusitana* (1899) and *Os Arcades* (1918); Hernâni Cidade, *Lições de cultura e literatura portuguesas*, vol. II (1940); A. J. Saraiva and O. Lopes, *História da literatura portuguesa* (1954). (N. J. L.)

**CRWTH**, a Welsh stringed instrument that became extinct early in the 19th century, known also in medieval England (the *crowth* or *crowd*). Basically it is a lyre (*q.v.*), but from about 1300 it was given a fingerboard and played with a bow like a fiddle, one or more strings lying off the fingerboard for "drone" use.

(A. C. BA.)

**CRYOGENICS**: see LOW-TEMPERATURE PHYSICS.

**CRYOLITE**, a mineral discovered in Greenland, in 1794, is a sodium aluminum fluoride. The principal use of cryolite is in the electrolytic production of aluminum (*q.v.*), where it serves as an electrolyte. Cryolite also has numerous other metallurgical applications, is used in the glass and enamel industries, in bonded abrasives as a filler, and in the manufacture of insecticides.

Cryolite is found in a large deposit at Ivigtut in the Arksukfiord, Frederikshaad district, west Greenland. It occurs as a pegmatitic body in a granite stock intrusive into gneiss. Cryolite also has been found in small amounts in the U.S.S.R., Spain and in Colorado. The deposit at Ivigtut is the only natural commercial source of cryolite. A large proportion of the cryolite used in industry each year is produced synthetically from calcium fluoride or fluorite (*q.v.*).

The formula of cryolite is  $\text{Na}_3\text{AlF}_6$ . Its crystals are monoclinic. It is usually massive with no cleavage but having pseudocubic parting and uneven fracture. Other principal physical properties include: hardness 2.5; specific gravity 2.97; lustre vitreous to greasy; colour white, also brownish, reddish, rarely black; refractive index 1.338; maximum birefringence 0.001. (G. S. SK.)

**CRYPT**, a vault or subterranean chamber, especially under a church floor. In Latin, *crypta* designated any vaulted building partially or entirely below the ground level, such as a sewer, the vaulted stalls for horses and chariots in a circus, farm storage cellars and a long, vaulted gallery known as cryptoporticus, like that on the Palatine hill. The tunnel to the north of Naples now known as the Grotto of Posilipo, through which passes the road to Pozzuoli (anc. Puteoli), was called *crypta Neapolitana* by Seneca. It was natural, therefore, for the early Christians to call their catacombs (*q.v.*) crypts, and when churches came to be built over the tombs of saints and martyrs, subterranean chapels, known as *confessiones*, around the actual tomb, were included. These also were called crypts. The most famous of these was St. Peter's, built on the site of St. Peter's martyrdom, over the circus of Nero (4th century).

Other notable Roman examples are those of S. Prisca, S. Praxedes and S. Lorenzo fuori le Mura. In the basilica of S. Maria Maggiore a crypt was furnished, although there was no tomb or martyrdom site to commemorate; thus, as early as the reign of Constantine, the crypt was considered a normal part of the church building.

Further incentive to the building of crypts was given by the growing practice of burials within the church walls. This was a much debated usage, and the Council of Braga (563) gave permission for burials only within the churchyard, but not within the church itself. The Council of Mainz (813), however, stated that bishops, abbots, worthy priests or loyal laymen might be buried in a church, and from that time burials within the church multiplied. These were usually in the crypt. An early example of such a burial crypt exists in the church of S. Apollinare in Classe, Ravenna (6th century), where it takes the form of a small, underground passage around the altar and just within the apse walls.

Later the size of the crypt was increased to include the entire space under the floor of the church choir or chancel, as in the 10th-century crypt of S. Ambrogio at Milan. With the increased desire for richness in all parts of the church and increased technical skill, a further step was taken by raising the choir floor boldly and opening the front of the crypt to the nave, which was on an intermediate level between the crypt and the choir, with monumental flights of

ALINARI

FIG. 1.—VAULTED CRYPT OF S. MINIATO, FLORENCE (1013)

steps leading down to the crypt in the centre and up to the choir on either side. The arcaded fronts of these crypts formed an effective decoration for the church, as in the 12th-century church of S. Zeno in Verona, and that of S. Miniato at Florence (1013). The latter is particularly rich with inlaid polychrome marbles. Within, these crypts were usually apsidal and the ranges of columns whose vaults supported the floor above gave interesting perspective effects.

Where Byzantine influence was strong, crypts were less common, and when found, were of a totally different type, frequently existing as cellars under the entire church area, as in Trani cathedral in southern Italy (12th century). St. Mark's at Venice has a remarkable crypt of Greek cross plan, with many short and stumpy columns. This crypt was, in fact, a secondary church; its choir screen is still extant.

Outside Italy there was great variation both in frequency and in size of crypts. Lombard influence in Germany was shown by the large number of Rhenish churches that followed the Italian precedent of an appreciably raised choir with an important crypt beneath it. The end beneath the nave was usually closed, however. Elsewhere in western Europe the choir level was much less raised, and the crypt, where present, tended more and more to become a lower church with a plan largely reproducing that of the church above. The cathedral of St. Bénigne at Dijon possesses the strange crypt of a curious round chapel which seems to date back to the 6th century. It was built over the tomb of the patron saint and is peculiar in the fact that the central circular area, surrounded by a double aisle, ran up through the upper portion of the building and was open to the sky.

There is also a remarkable crypt in the cathedral of Auxerre believed to date from 1085, and several examples in Normandy, notably that of Bayeux and the Abbaye aux Dames at Caen, both of the late 11th century. These are in a crude Norman style with many similarities to contemporary crypts in England. The crypts of Chartres and Bourges cathedrals deserve notice as instances of the more developed type of early Gothic of the late 12th and early 13th centuries.

Crypts were highly developed in English work throughout the Romanesque and Gothic periods. The one at Canterbury, the western half of which is attributed to Ernulf (*c.* 1100), and the eastern half to William the Englishman, 75 years later, forms a large and complex church, with apse and chapels. The extreme east end, under Trinity chapel, is famous as the original burial place of Thomas à Becket. Slightly earlier (late 11th century), the crypts of Winchester, Worcester and Gloucester are similarly apsidal but simpler in plan. Of these, Worcester (1084) is the most decorative. Parts of the crypt at Rochester, that at Hereford and the crypt, no longer existing, of old St. Paul's in London were of rich Gothic type, the last so large that it served as the parish church of St. Faith. Other notable examples in Great Britain are

the exquisite crypt of St. Stephen's chapel at Westminster, now incorporated within the houses of parliament, and the richly carved 13th-century crypt of the cathedral at Glasgow.

Small crypts under parish churches are common in England, as at Lastingham in Yorkshire (probably 1080), notable for its size and the crude pseudoclassic character of its ornament, and at Repton in Derbyshire. Another very fine Norman example is the crypt of St. Peter's-in-the-East at Oxford.

Technically, many medieval houses may be said to have had crypts, as they were built over vaulted substructures, and remains of such nonecclesiastical crypts occur widely throughout Europe. The German *Rathäuser* have many fine and richly decorated crypts, such as the famous cellar of the Bremen town hall; a notable monastic cellar still exists in Mainz, and the cellars of the residential buildings at Mont St. Michel in France furnish numerous examples of great size and magnificence in almost all the medieval styles dating from the 11th to the 15th century. Oxford, Rochester and Bristol, in England, contain many remains of vaulted medieval cellars, and the city of Chester is built, in great areas, over ranges of such vaults.

Notable examples in London are those of Gerard's hall, now destroyed (reign of Edward I), and of the Guildhall, which dates from 1411 and is notable for its rich and intricate ribbed vault, in the design of which the subsidiary ribs, called *liernes*, play an important part.

A. F. KERSTING

FIG. 2.—EARLY ENGLISH GOTHIC CRYPT AT HEREFORD CATHEDRAL, ENGLAND

Many great modern cathedrals contain crypts. Notable examples exist at Washington, D.C., and in New York city, where the crypt at the cathedral of St. John the Divine contains an elaborate mosaic altar and reredos.

(T. F. H.)

**CRYPTOLOGY** (CRYPTOGRAPHY) is the science concerned with the methods and the paraphernalia employed in secret communications (from Gr. *kryptos*, "hidden," and *logos*, "word"). Because of the growth of governments, the expansion of commerce and especially the remarkable progress made in communications-electronics technology, cryptology has come to play a very important role in governmental communications, especially diplomatic and military. It also plays a minor role in commercial, industrial and banking communications. Among the more uncommon uses of cryptology are those in connection with attempts to establish authorship in questionable cases, as, for example, that of the Shakespeare plays.

In its early stages cryptology was concerned almost exclusively with secrecy in written communications, and this article will be restricted very largely thereto, but the science has developed to the stage where it deals not only with enciphered writing (cryptograms) but also with other mediums of cryptocommunication, such as enciphered telephony (ciphony) and enciphered facsimile (cifax) transmissions.

Cryptology embraces the twin or complementary sciences of

signal security and signal intelligence. The former deals with all the means and methods of protecting one's own signals against interception and reading or utilization by unauthorized persons generally referred to as "the enemy." The latter deals with all the means and methods employed in acquiring information or intelligence by intercepting and solving the enemy's cryptosignals or nullifying his signal security so that the signals or information derived from them can be used against him.

**Signal Security.**—The principal components of this phase of cryptology are: (1) physical and personnel security; (2) transmission security; and (3) cryptosecurity. The first deals with the precautions and measures taken to assure that the physical arrangements and the facilities or procedures for safeguarding the paraphernalia or cryptomaterials used, i.e., the codes, ciphers, key lists, etc., are adequate for the purpose and that the personnel employed in operating the codes and ciphers or cipher machines are trustworthy. The second component deals with the means, methods and procedures for assuring that no information is inadvertently disclosed either by indiscretions of operators or by faults in the transmitting or receiving apparatus which may assist in the solution of the transmissions. The third component, cryptosecurity, which deals with the technical adequacy of the cryptosystems employed, is usually of greater interest and deserves more extensive treatment than the other two. In an article of this nature it is possible only to deal briefly with cryptography (from Gr. *kryptos*, "hidden," and *graphein*, "to write"), it being understood that many of the cryptoprinciples employed for the protection of written communications, or signals representing them, can also be used in protecting or disguising other types of cryptosignaling; e.g., ciphony and cifax. Cryptography deals with the processes, methods or means involved in preparing cryptograms; that is, messages or writings which are intended to be incomprehensible except to those who legitimately possess the proper special paraphernalia and the keys for those cryptograms and know how to use them in order to reproduce the original plain text of the messages. These processes are usually accomplished by means of cryptosystems employing codes or ciphers. The process of converting a plain-text message into a cryptogram is called enciphering (or encoding); that of reconverting the cryptogram back into its intelligible form, when done by a legitimate or authorized communicator, i.e., one who legitimately holds the paraphernalia and the key, is called deciphering (or decoding).

Although in theory no sharp line of demarcation can be drawn between code systems and cipher systems, in modern practice the technical differences between them are sufficiently marked to warrant their being treated as separate categories of methods. Some authors include as a third and separate category the extensive but much less important one containing the so-called "concealment systems," which are sometimes employed to hide an internal or secret message within an external or apparently innocent piece of writing with a view to avoiding arousing suspicion in the minds of persons not privy to the secret, or to eluding censorship in wartime. In such systems the message or its elements are hidden or disguised by any one of hundreds of different means and methods, including such mediums as secret or invisible inks, microscopic writing, etc., but none of these concealment systems or devices will even be mentioned again herein. It is convenient to consider cipher systems first, then code systems, with the understanding that only a very few of the limited number of systems suitable for serious usage can here be outlined.

**Cipher Systems.**—In general, cipher systems involve a cryptographic treatment of textual units of constant and equal length usually single letters, sometimes pairs, rarely sets of three letters these textual units being treated as symbols without reference to their identities as component parts of words, phrases and sentences. Every practical cipher system must combine (1) a set of rules, processes or steps constituting the basic cryptographic method of treatment or procedure, called the general system which is agreed upon in advance by the communicators and which is constant in character, with (2) a specific key which is variable in character. In enciphering plain text, the specific key, which

may consist of a number or a series of numbers or a word, phrase, sentence, etc., controls the steps under the general system and determines the specific nature or exact composition of the cipher message produced; in decipherment the specific key similarly controls the steps and determines what the deciphered text will be. When all operations are performed correctly, the two plain texts (before and after the cryptography) should be identical or nearly so, save for minor differences arising from errors in their encipherment and transmission or in their reception and decipherment. The general system should be such that even if it is known to the enemy no properly enciphered message can be read by him unless he also knows the specific key or keys applicable to that message.

Despite a great diversity in the external appearance and internal constitution of ciphers, there are only two basic classes of systems—transposition and substitution. (Concealment ciphers are excluded from the discussion.) A transposition cipher involves a rearrangement or change in the sequence of the letters of the plain-text message without any change in their identity; a substitution cipher involves a replacement of the plain-text letters by other letters (or by other symbols) without any change in their sequence. The two systems may be combined in a single cryptosystem.

AINLU UIPTR DUHDR  
LO

Fig. 1.—An example of simple columnar transposition. The numerical key is derived by numbering the letters of the keyword ("telegraph") in accordance with their relative order of appearance in the ordinary alphabet, repeated letters, if present in the key, being numbered in sequence from left to right. The message is written in the normal manner from left to right in successive horizontal lines underneath the key, forming a "rectangle" of columns of letters. These letters are then transcribed in regular groups of five from the rectangle by reading down the columns, taking the latter in the sequence indicated by the key numbers. The last line of the rectangle may be completely filled with letters, nonsignificants being added if necessary; but the security of the method is considerably increased if the last line shows one or more blank spaces, as in this example.

The majority of transposition systems involve inscribing the letters of the plain text in a geometrical design called a matrix, beginning at a prearranged initial point and following a prescribed route, and then transcribing the letters from the matrix, beginning at another prearranged initial point and following another prescribed route. The matrix may take the form of a rectangle, trapezoid, octagon, triangle, etc., but systems in which the specific keys consist solely in keeping the matrices, the initial points and the routes secret are not often now employed because of their limited variability and, therefore, their relatively low degree of security. In this same class also fall systems which employ perforated cardboard matrices called grilles, descriptions of which will be found in most of the older books on cryptography. The transposition system most commonly used in practice is that designated as columnar transposition, wherein the transposition matrix takes the form of a simple rectangular figure the dimensions of which are determined in each instance jointly by the length of the individual message and the length of the specific key. An example is shown in fig. 1.

In the foregoing case the letters undergo a single transposition; in cases involving double transposition, that is, wherein the letters undergo two successive transpositions, the security of the cryptograms is very greatly increased, provided the methods selected are such as will effectively disarrange individual letters and not merely such as will effectively disarrange individual letters and not merely whole columns or rows. A practical system of double transposition is illustrated in fig. 2. The principal advantages of transposition systems lie in their comparative simplicity, speed of operation and, in some cases, their high degree of security; but despite these important considerations they do not at the present time play a prominent role in practical cryptography.

Substitution systems involve the use of conventional or cipher

Fig. 2.—An example of true double transposition. The cipher letters resulting from the first transposition rectangle (a) are written under the key of the second transposition rectangle (b) just as though they constituted plain-text, that is, from left to right, in successive horizontal rows. The final transposition is then performed in exactly the same manner as in fig. 1, yielding five-letter groups. The two rectangles may be based upon the same keyword, as in this example, or upon wholly different keywords.

alphabets composed of two juxtaposed sequences, one (either expressed or implied) corresponding to the letters of the ordinary alphabet (a, b, c . . . x, y, z), the other containing their respective cipher equivalents. The complexity of a substitution system usually depends upon three factors: (1) the specific composition of the cipher alphabet or alphabets employed; (2) the number of them involved in a single cryptogram; and (3) the specific manner in which they are used. As to their composition, cipher alphabets are of various types and are known under various names, such as standard, direct, reversed, systematically mixed, key-word mixed, random mixed, reciprocal, etc., all having reference to the nature of the two sequences composing them, the interrelations existing among them internally or externally, etc. The most important factor in connection with a cipher alphabet is whether its two sequences, regardless of their composition, are known or unknown to the enemy; for, if known, any conventional or disarranged alphabet may be handled with the same facility as the normal alphabet. As to the number of alphabets involved in it, a cryptogram is either monoalphabetic, involving a single cipher alphabet, or polyalphabetic, involving two or more alphabets. In essence the difference between the two types lies in the fact that in the former the equivalence between plain-text and cipher letters is invariant, i.e., the equivalence is of a constant or invariable nature throughout the cryptogram, whereas in the latter it is of a changing or variable nature, controlled by the key. With regard to secrecy, the third condition mentioned above, namely, the specific manner in which the various cipher alphabets are employed, is the most important in determining the degree of security or resistance the cryptogram will have against cryptanalysis, as explained below.

Monoalphabetic substitution is usually unilateral; i.e., each letter of the plain text is replaced by a single character. Cases of bilateral, trilateral, etc., substitution are sometimes encountered; an example using bilateral equivalents is shown in fig. 3. No matter how many characters are in the groups composing the cipher equivalents for plain-text letters, if the groups are always the same for each letter, the substitution system is still monoalphabetic and the cipher can be treated as such.

Fig. 3.—An example of bilateral, monoalphabetic substitution. A keyword alphabet of 25 letters (I serving also for J) is written in a square 5 x 5. (In this case the alphabet is based upon the word "telegraph.") The letters (A, B, C, D, E) at the side and top of the square, taken in pairs, can then be used to represent the letters within the square. Thus, D=CA, E=AB, etc. The letters at the side of the square may be the same as or different from those at the top; in both cases keywords, identical or different, may be used instead of the letters A, B, C, D, E.

using the fewest code groups possible. As to their cryptographic construction or arrangement of contents, codes may be of the one-part or the two-part type, the principal difference between them being shown in fig. 7.

Fig. 7.—Extracts from typical one-part and two-part codes. In the one-part type the code groups and the vocabulary are arranged in parallel, alphabetic (or numerical) sequences, so that a single book serves for encoding as well as for decoding. In the two-part type the encoding book lists the elements of the vocabulary in alphabetic order but the code groups are in random order, so that a decoding book, in which the code groups appear in alphabetic (or numerical) order accompanied by their meanings, is essential. The degree of secrecy afforded by a code of the latter type is much greater than that afforded by one of the former type, all other things being equal.

The condensing power of a code obviously depends upon the extent and the nature of its vocabulary. The security of a code system depends somewhat upon the distribution and construction of the codebook, but mostly upon whether it is used in conjunction with a good cipher system which is superimposed on the code text and the purpose of which is to afford secrecy, in the case of purchasable or publicly available codes, or additional secrecy, in the case of private or governmental codes. Code messages which undergo this second step are said to be superenciphered, reenciphered, or simply, reciphered. The principal purpose of code in commercial communications is to effect economy in their cost of electrical transmission, secrecy being usually of secondary importance (except in certain types of banking operations). Codes for general business communications are purchasable from their publishers and therefore in themselves provide no secrecy. Many business firms, however, use specially compiled private codes which, if carefully restricted in distribution, may be regarded as confidential or secret. In governmental and especially in diplomatic or military communications secrecy is generally of primary importance, economy is secondary.

Governmental codes which are intended to be secret are, of course, very carefully guarded in their production, distribution and usage and, as a general rule, messages in such codes are superenciphered.

**Cryptoparatus.**—Cryptodevices and cryptomachines vary in complexity from simple, superimposed, concentrically or eccentrically rotating disks to large mechanical machines and electrically operated cryptoteleprinting apparatus. One of the best devices of the more simple, mechanical type is that known as the Bazeries cylinder (see fig. 8), named after the French cryptographer who is commonly credited with its invention in 1891. The principle upon which the device is based was, however, conceived many years before by Thomas Jefferson (see Jefferson's *Papers* in the Library of Congress, vol. 232, item 41,575).

Devices of the sort exemplified in fig. 8 soon proved to be in-

FIG. 8.—THE BAZERIES CYLINDER

The Bazeries cylinder consists of a set of 20 disks, each bearing on its periphery a differently mixed alphabet. The disks, which bear identifying numbers from 1 to 20, are assembled on the shaft in an order that corresponds to a numerical key. To encipher the message, 20 letters are taken at a time, and the disks are revolved so as to align the 20 letters horizontally; the letters of any row can be taken for the cipher text. In deciphering, the cipher letters, taken 20 at a time, are aligned horizontally; the disks are then looked into position. By slowly revolving the whole cylinder and examining each row of letters, one and only one row will be found to yield intelligible text all the way across

adequate for modern cryptocommunications, as regards not only speed, accuracy and facility in operation but also security of the end product. It was not long, therefore, before more automatic and more secure types of apparatus were invented and developed. In such apparatus rotatory components referred to as cipher rotors have come to be of primary importance. The rotors may be of a mechanical or an electrical type. Fig. 9 shows a machine which uses a series of mechanical rotors to produce an extremely long, continuously changing key for encipherment. Although the results of manipulating the machine are printed upon a paper tape, the absence of a typewriter keyboard makes operation of the machine slow and tedious. Another machine uses a series of juxtaposed electrical rotors and stators to form a path for the passage of electric currents connecting the 26 keys of a keyboard to the 26 lamps of a light board upon which the results of manipulating the keys are indicated. Automatic angular displacements of the rotors serve to vary the path with each depression of any key of the keyboard. From a practical point of view such a machine is not satisfactory for offices engaging extensively in cryptocommunication since it lacks an automatic recording or printing mechanism and the results of operating the keyboard have to be recorded by the operator by hand. Therefore a machine combining both a keyboard and a printing mechanism had to come sooner or later. Such a combination of components is shown in

FIG. 9.—PORTABLE CRYPTODEVICE WHICH PRODUCES A PRINTED RECORD OF THE CIPHER TEXT AS WELL AS OF THE PLAIN TEXT

The letters to be enciphered or deciphered are set by twirling the indicating disk shown at left and operating the lever at the right. The six wheels control the cryptography, in conjunction with certain other variable keying elements inside the machine

fig. 10. Machines of this type, which are not necessarily associated with the electrical communication system but which merely produce an end product (a printed record) that can be given to a communication centre or telegraph office for transmission, are called off-line cryptomachines.

But even this stage in improvement in cryptocommunications proved inadequate and communicators soon began to see need for on-line cryptomachines; i.e., apparatus which combines in a single and instantaneous operation the following steps: (1) manipulation of a key of the keyboard at the transmitting station to correspond to a character of the plain-text message; (2) automatic encipherment of that character to form a cipher character; (3) electrical representation of that character by a signal or a permutation or combination of signals corresponding to the cipher character; (4) electrical transmission of the signal or signals; (5) their reception at the distant end; (6) their translation into a cipher character; (7) automatic decipherment of the character; and (8) printing the deciphered character—all this at the rate of at least 300 characters (=60 words) per minute. It is obvious, of course, that machines of this advanced type can be employed only where

FIG. 10.—CRYPTODEVISE OF FIG. 9 EQUIPPED WITH A KEYBOARD AND DRIVEN BY AN ELECTRIC MOTOR

The two machines are cryptographically intercommunicable. The operating lever at right is used in case of power failure

there is direct access to transmission and reception facilities.

As a result of extensive research and development after 1920, machines of the sorts here described have undergone considerable improvement, and further progress in written-cryptocommunications technology appears to lie in this direction.

**Signal Intelligence.**—The principal components of signal intelligence are: (1) communication intelligence, derived from the interception and analysis of signals which are involved in the exchange of messages or communications between persons and which are therefore of the type designated as communication signals; and (2) electronic intelligence, derived from the interception and analysis of electromagnetic radiations which are of a type other than those used in communications, such as radar, identification and recognition signals, navigational beacons, etc., and which are therefore designated as noncommunication signals. It should be noted, however, that it is often difficult to draw a line of demarcation between communication intelligence and electronic intelligence because these two fields deal with signals which merge into each other in the continuous spectrum generally referred to as that pertaining to communications electronics. (See SIGNAL COMMUNICATION, MILITARY.)

**Communication Intelligence.**—This phase of cryptology deals with the processes, methods or means employed in deriving information by intercepting and analyzing enemy communications. Its principal components are: (1) interception and forwarding of traffic (messages) to analysis centres; (2) traffic analysis, including radio direction or position finding and operator identification; and (3) cryptanalysis or solution (and translation, when necessary) of the texts of the messages. Only the last two components will be discussed.

**Traffic Analysis.**—Stated in general terms, traffic analysis involves studying the messages exchanged within a communications network for the purpose of penetrating the signal security camouflage superimposed thereon.

Such study permits reconstructing the networks from data such as volume, direction and routing of messages, frequencies, schedules and call signs used, etc. When the most important features of the networks have been thus ascertained, the analyst is not only able to ascertain the geographic locations and dispositions of military units (order of battle) and important movements of these units, but also to predict with varying degrees of reliability (based upon inferences) the area and extent of future military tactical or strategic operations.

**Cryptanalysis.**—The science of solving cryptograms by anal-

ysis is called cryptanalysis, to distinguish the indirect methods of reading cryptograms from the direct methods which, of course require a knowledge of the basic method and specific key, in the case of ciphers, or possession of the codebook, in the case of codes. Apart from the more simple, classical types, nearly every scientifically constructed cryptographic system presents a unique case in cryptanalysis, the unraveling of which requires the exercise of unusual powers of observation, inductive and deductive reasoning, much concentration, perseverance and a vivid imagination; but all these qualities are of little avail without a special aptitude arising from extensive practical experience. It is worthwhile to note that the resistance which a specific cryptosystem will have against cryptanalysis is often vitally affected by the sophistication of the rules for its use and by the degree to which these rules are observed by cipher clerks. In respect to the latter, Francis Bacon's comment in his *Of the Advancement of Learning* (1605) is as true today as the day it was written: "But in regard of the rawnesse and unskillfulnesse of the hands, through which they passe, the greatest Matters, are many times carried in the weakest cyphars."

A preliminary requisite to the analysis of a cryptogram is a determination of the language in which its plain text is written, information which is either already at hand in the case of official communications or which, in the case of private ones, can usually be obtained from extraneous circumstances. Next comes a determination as to whether a cipher or a code system is involved; this is based upon the fact that differences in their external appearance are usually sufficiently well marked to be detectable. If the cryptogram is in cipher, the next step is to determine whether transposition or substitution is involved. This determination is made on the basis of the fact that in plain text the vowels and consonants are present in definite proportions. Since transposition involves only a rearrangement of the original letters, it follows that if a cryptogram contains vowels and consonants in the proportions normally found in plain text in the language in question, it is of the transposition class; if not, it is of the substitution class. The solution of transposition ciphers involves much experimentation with matrices of various types and dimensions, clues to which are afforded by the number of letters in the messages and extraneous circumstances. The assumption of the presence of probable words is often necessary. Special methods of solution based upon a study of messages of identical lengths, or with identical beginnings or endings, are often possible to apply when much traffic has been intercepted. Finally, the presence of letters which individually are of low frequency but which when present have a great affinity for each other and form pairs of moderate or high frequency, such as *qu* in Spanish or *ch* in German, afford clues leading to solution.

The basis upon which the solution of practically all substitution ciphers rests is the well-known fact that every written alphabetic language manifests a high degree of constancy in the relative frequencies with which its individual letters and combinations of letters are employed. For example, English telegraphic texts show the following relative frequencies in 1,000 letters, based upon an actual count of 100,000 letters appearing in a large but miscellaneous assortment of telegrams of a commercial and governmental nature, but all in plain language:

E	T	R	I	N	O	A	S	D	L	C	H	F
128	90	83	78	76	74	72	58	40	36	33	33	30
U	P	M	Y	G	W	V	B	X	K	Q	J	Z
30	27	26	21	18	14	13	11	6	3	3	2	1

These characteristic relative frequencies serve as a basis for identifying the plain-text values of the cipher letters, but only when the cipher has been reduced to its simplest terms. Thus the problem of solving a monoalphabetic substitution cipher involves only one step, since the text is already in the simplest possible terms and regardless of the kind of cipher alphabet employed practically every example of 25 or more characters representing the monoalphabetic encipherment of a "sensible" message in English can readily be solved by the well-known principles of frequency, made popular by Edgar Allan Poe's romantic tale *The Gold Bug*. How-

ever, the problem of solving a polyalphabetic substitution cipher involves three principal steps: (1) determining the number of cipher alphabets involved; (2) distributing the cipher letters into the respective individual frequency tables to which they belong; and (3) analyzing each of the latter on the basis of normal frequencies in plain text of the language involved. In the case of aperiodic ciphers, because of the absence of cyclic phenomena, these steps are often very difficult, especially when the volume of text is limited. Frequently the only recourse is to employ repetitions as a basis for superimposing separate messages so that, irrespective of the number of alphabets involved or their sequence, the letters pertaining to identical cipher alphabets fall into the same columns, and then the respective columns are treated as monoalphabetic frequency tables. The analysis of the frequency distributions of a polyalphabetic cipher is effected much more readily when the alphabets are interrelated than when they are independent.

The question as to whether an absolutely unsolvable cipher system can be devised is of more interest to laymen than to professional cryptographers. Edgar Allan Poe's dictum that "it may be roundly asserted that human ingenuity cannot concoct a cipher which human ingenuity cannot resolve" is misleading unless qualified by restricting its application to the great majority of the practical systems employed for a voluminous, regular correspondence. Isolated short cryptograms prepared by certain methods may resist solution indefinitely; and a letter-for-letter cipher system which employs, once and only once, a keying sequence composed of characters or elements in a random and entirely unpredictable sequence may be considered holocryptic, that is, messages in such a system cannot be read by indirect processes involving cryptanalysis, but only by direct processes involving possession of the key or keys, obtained either legitimately, by virtue of being among the intended communicators, or by stealth.

**History.**—It may as well be stated at the outset that at mid-20th century there did not exist in any language a detailed, authentic and publicly available history of cryptology. Moreover, because of the curtain of secrecy which is invariably placed around cryptologic work of an official character, accurate accounts of historically important events or of noteworthy inventions and improvements in cryptologic technology usually enter into the public domain only many years after the event or invention has occurred. Therefore, although it is difficult or impossible to ascertain with certainty much about the origin of any specific item or fact of cryptographic or cryptanalytic importance, the data should be traced back at least as far as the open or public records will permit.

With this limitation kept in mind, this account will begin by noting that secret modes of signaling and communication have probably been in use from the earliest times, since the desire or need for secrecy in communication is certainly as old or nearly as old as the art of writing itself. However, mysteries such as the prophetic and apocalyptic writings of the orient and the sayings of the Sibylline oracles are generally not regarded by cryptologists as coming within their province; nor do they generally do anything more than merely refer to the various systems of stenography or shorthand used since the time of the Romans, including that known as Tironian notes, named after Tullius Tiro, Cicero's learned freedman and friend, who elaborated a system which was popular for almost 1,000 years. Although it is valid to assume that cryptography was used by all of the peoples of antiquity, the assumption has been confirmed in the case of Egyptian hieroglyphic writing by the outcome of studies which were begun by Jean François Champollion and which culminated in 1932, disclosing that not one but three different sorts or degrees of cryptography were actually used by the ancient Egyptians. Cryptography was practised among the ancient Jews, whose Talmudic scholars dealt with it as a part or phase of their Cabala, which includes certain operations of a cryptographic nature. The ancient Greeks were users of the art, and at least one cryptographic device, called the scytale, is known to have been employed by the Lacedaemonians for secret communications between military commanders in the field and their superiors at home.

Aeneas Tacticus (4th century B.C.) wrote the very earliest treatise on cryptography thus far discovered; in addition to treating of secret dispatches, it contains a description of a cipher disk, a detailed explanation of which cannot here be included. Numerous ancient Greek documents exist which are either partially or wholly in cipher; and one cipher alphabet found therein has been traced back to the 9th century A.D. Despite the fact that Roman cryptographic documents are rather rare, it is well known that the Romans used ciphers, for there are numerous references to those which Caesar and Augustus employed. In fact, the name Caesar is often used in cryptologic literature to designate the type of cipher alphabet and cipher system known as the monoalphabetic cipher using standard alphabets. In the middle ages (c. 450–1450) cryptography was employed rather infrequently, for the most part in connection with the pseudo sciences of alchemy and astrology. The most widespread cryptographic system of that period corresponds to that used by the Roman emperor Augustus, in which a letter was merely replaced by the one following it in the normal alphabet (but z was replaced by aa). Most often, however, only certain letters were thus replaced, sometimes only the vowels.

The beginnings of modern cryptography can be traced back to Italy, the birthplace, as well, of modern diplomacy. Many cipher alphabets have come down to us which were used in the official messages of the papacy as well as in those of the early Italian republics. Ciphers were used in Venice as far back as in 1226; in Mantua and in Modena as early as 1305; and in Lucca, Florence, Siena, Pisa and Milan before 1450. It was also in Italy, beginning soon after 1500, that cryptologic operations first came to be organized on an effective basis. The invention of new cipher systems was promoted, and reserves of cryptographic vocabularies were prepared and kept in readiness for prompt issue as replacements for old or compromised ones. The earliest extant piece of work of a cryptographic nature is a small manual or compilation of the ciphers used about 1379 by Gabriel de Lavinde of Parma and preserved in the Vatican archives. In these ciphers all the letters were represented by arbitrary symbols, and the vowels were treated no differently than the consonants in regard to the number of equivalents assigned them. However, some of these ciphers included nulls and others included brief lists of words and proper nouns, compilations first called nomenclators, then repertoires and, later, small codes. By 1400 it had become apparent that each of the vowels should have more than a single cipher equivalent, and there is a record of a cipher system involving a reversed standard alphabet with three different supplementary symbols as variants for each vowel. By the 15th century, according to Aloys Meister, Italian cryptography had been elaborated to the point where "three to six different symbols could be used to represent a single letter of the alphabet, the individual syllables—arranged alphabetically for this purpose, ba, be, bi, bo, bu, ca, ce, ci, etc.—had specific cipher equivalents, and an ever increasing number of complete words were incorporated into the nomenclators. Their abundance in content became so great that it was possible to fill a lengthy alphabetic index with the special equivalents for syllables and words. . . ." The first complete cipher, i.e., one containing arbitrary symbols for each of the letters and variants for the vowels as well as nulls and a nomenclator, is exemplified by a Venetian cipher of 1411 cited by Luigi Pasini. In the first half of the 15th century, after some further expansion in content, nomenclators attained such a state of development and practical utility that they remained for centuries the prototype of the diplomatic repertoires used by nearly all European governments, as well as by that of the young and rapidly growing republic in the western hemisphere, the United States.

Before continuing the account of cryptosystems of this sort, it may be well to direct attention to the invention and development of another cryptosystem which, originating in the very simple devices of the ancients, culminated some time during the 16th century in the so-called *chiffre indéchiffrable* ("the indecipherable cipher"), often referred to as the Vigenère cipher (fig. 4). It should be noted, however, that Vigenère's description of the cipher differs decidedly from the form usually ascribed to

him and presents an essentially more difficult problem to the cryptanalyst, that Vigenère nowhere speaks of the cipher as the *chiffre indéchiffrable par excellence* and that, except for an auto-keying principle, Vigenère lays no claim to having originated the cipher.

Despite the much advertised virtues and security of the Vigenère cipher, practical cryptographers and cryptanalysts tended to put their faith rather in the older nomenclators and repertoires, and it is therefore necessary to turn once more to these cryptoids and follow their progress.

The repertoires used by France in the 16th century under Louis XIII and Louis XIV underwent important improvement with the introduction of an innovation which is now called the randomized or two-part arrangement of contents, illustrated in fig. 7. This improvement also soon found its way into the official cryptography of England and other countries. The repertoires used by the papal court in the same century incorporated an additional new feature, that of making some or all of the cipher characters represent two or more different letters. After attaining this fairly advanced state of development, European cryptography went into a decline that reached its lowest level under Napoleon I; it is possible that one of the factors leading to the disaster which overtook him in Russia was the solution by the Russians of intercepted French ciphers. After the middle of the 19th century, stimulated perhaps by the spreading use of electromagnetic telegraphy, there came an expansion in the content of repertoires, soon to be called codes. By the end of that century large codes containing 100,000 or more words and phrases were compiled not only for governmental but also for commercial communications. In such codes, of course, the length of the code equivalents had to be increased too, and code groups came to be composed, first, of groups of figures or of bona fide dictionary words, then of artificial words and, later, of five-letter groups constructed scientifically so as to obtain the maximum not only in economy in cost of transmission but also in efficiency in the correction of transmission errors. For another 75 years, beginning about 1860, the cryptoprinciples embodied in the early nomenclators but now expanded into large codes were the ones preferred for diplomatic and commercial cryptocommunications; literal or letter-for-letter ciphers were used only rarely for such communications. On the other hand, for military cryptocommunications, cipher systems of the latter type were preferred, except for high-level or strategic communications. In the U.S., during the Civil War (1861-65), the Federal army employed small repertoires in connection with word transposition, the so-called route cipher. The Confederate army used the Vigenère cipher—which the Federal army cryptanalysts are said to have been able to solve every time a message in it was intercepted.

During the first two years of World War I, cipher systems were used almost to the exclusion of code systems by all belligerents for protecting tactical communications in the field of operations, although code systems continued to be used for diplomatic and high-level strategic military cryptocommunications. By 1917, however, codes came to be used for the secret communications of the smaller and intermediate-size military formations. The extent of their vocabularies varied with the size of the unit, so that the code for communications between large units might contain 10,000 words and phrases, whereas that for communications between small units might contain only a few hundred or less. After about 1925 the direction of development and improvement in governmental cryptocommunications tended to explore and exploit the possibilities of automatic cipher machines, as indicated earlier in this article, and this took place in all types of secret communications: diplomatic, military, naval, air, etc. This change in direction of evolution and development of cryptosystems, code systems giving way to cipher systems in practical cryptocommunications where secrecy is the primary consideration, is only an obvious result, in the field of communications, of the increased tempo of mechanization in all fields since the beginning of the 20th century. Cipher systems, the units of which are generally single letters, lend themselves much more readily to mechanization than do code systems, the units of which are

generally complete words and often long phrases or sentences, because the number and lengths of different permutations and combinations of electrical signals needed to represent the relatively small number of different basic units of a written alphabetic language (in English 26 letters) are very much smaller than the number and lengths of different permutations and combinations that would be required to represent the large number of different words in such a language, not to mention long phrases and sentences.

This brief account of technological developments in cryptography has its counterpart in cryptanalysis, but if it is difficult to ascertain with certainty data concerning the origin of any specific cryptosystem because of the veil of secrecy already mentioned, it is almost impossible to ascertain with certainty by whom, where or when a specific cryptanalytic principle or process was first conceived or employed. The veil in this area becomes an almost impenetrable curtain, so that it is certainly valid to assume that news of cryptanalytic success or of the invention of a new technique becomes public only many years after the events or, perhaps, never.

Under these circumstances one hardly expects to find a historical account of the very first success in cryptanalysis, but the earliest brochure on record dealing with cryptanalytic theory is that of Leon Battista Alberti, whose *Trattati in cifra*, written between 1467 and 1472, deals not only with cryptanalytic theories and processes but also with cryptography and statistical data. It is, therefore, the oldest treatise on cryptology in existence. The brief treatise of Siccio Simonetta, a cryptanalyst of the Sforzas at the court of Milan, which is dated July 4, 1474, and which is a strictly practical guide to cryptanalytic procedures, is the oldest treatise in the world purely devoted to cryptanalysis. Beginning about 1506 and until 1539 another Italian professional cryptanalyst, Giovanni Soro, devoted his leisure hours to the preparation of a treatise which has never been found. As was the case with cryptography, so on the cryptanalytic side the activities in the various small Italian republics and the papacy came to be organized as serious enterprises. In order to protect these activities against indiscretions or leakage, the principles of secrecy and security were firmly established and willful violations were treated as capital offenses. The development of technical skill was rewarded, and instruction in cryptanalysis was often carried on from one generation to the next in the same family. But, as in the cryptographic field so in the cryptanalytic field, there have been periods of progression and retrogression in technology. However, after about 1930 cryptanalytic technology progressed rather notably. The mechanization which affected cryptography also affected cryptanalysis, and the invention and development or improvement of machines to aid in or speed up the tedious processes usually involved in the solution of complex cryptosystems exercised an important effect upon the standards by which cryptosecurity had to be measured.

The foregoing is a brief history of technological developments in cryptology. Nothing has yet been said about the usually very secret but quite important roles which poor cryptography or good cryptanalysis have played in international relations, both in peace and war, and in respect to both diplomatic and military affairs. As already stated, the historical accounts of these instances usually lag many years behind the events to which they relate. But in at least one case in modern history the revelation of the spectacular role played by cryptology in diplomacy and warfare took place not very long after the event. Hearings held in Washington, D.C., 1945-46, by the joint committee on the investigation of the Pearl Harbor attack, made it clear that shortly before and during World War II U.S. cryptanalysts had considerable success in solving Japanese codes and ciphers, success indeed to the extent that it was possible for the committee to state that all witnesses familiar with the intelligence produced "have testified that it contributed enormously to the defeat of the enemy, greatly shortened the war, and saved many thousands of lives." For other instances the reader must consult some of the books listed in the bibliography, but not many will be found that pertain to relatively recent history.

**BIBLIOGRAPHY.**—Although no comprehensive and authentic history of cryptology had been published by the 1950s, there does exist a comprehensive and scholarly bibliography covering practically all publicly available books and important papers on the subject: Joseph S. Galland, *An Historical and Analytical Bibliography of the Literature of Cryptology* (1945). Such a compilation is more helpful to specialists than to the general reader, therefore, a selection of items from the Galland bibliography may be useful. Also, after 1945 there were published a few items of importance which should be mentioned herein. Modern works worthy of special mention are as follows: André Lange and E.-A. Soudart, *Traité de cryptographie* (1925); Marcel Givierge, *Cours de cryptographie* (1925); Roger Baudouin, *Éléments de cryptographie* (1939); H. F. Gaines, *Elementary Cryptanalysis* (1939); Luigi Sacco, *Manuale di crittografia*, 3rd ed. (1947); Charles Eyraud, *Precis de cryptographie moderne* (1953). (W. F. F.)

**CRYPTOMERIA**, a genus of conifers native to Japan and containing a single species, *C. japonica*, known as cryptomeria, Japanese cedar or sugi. It is one of the finest of Japanese evergreen trees, the reddish-brown trunk reaching a height of 100 or more feet, usually divested of branches along the lower part and crowned with a conical head. The narrow, pointed leaves are spirally arranged and persist for four or five years; the cones are small, globose and borne at the ends of the branchlets; the scales are thickened at the extremity and divided into sharply pointed lobes; three to five seeds are borne on each scale. *Cryptomeria* is extensively used in Japan for reforestation denuded lands, as it is a valuable timber tree; it is also planted in temple gardens and along avenues. Many curious varieties have been obtained by Japanese horticulturists, including dwarf forms a few feet in height. Outside its native habitat cryptomeria often turns from its normal bluish-green to a bronzy colour during winter; it requires a deep, well-drained soil with plenty of moisture, and protection from cold winds.

**CRYSTALLITE**, a name given by Hermann Vogelsang in 1875 to the microscopical bodies occurring in many glassy igneous rocks, such as obsidian, pitchstone and tachylite (*q.v.*). Though possessing no distinct reaction under polarized light and often no recognizable crystallographic form, they are regarded as incipient crystals. The larger bodies, often with good crystal form and evident double refraction, are termed microlites.

According to their shape and structural arrangement crystallites are subdivided into globulites (small globules), margarites (coalescing globules arranged in rows), cumulites (cloudy aggregate of globules) and globospherites (groups of globulites with a radiate arrangement). Other crystallites assume threadlike forms (trichites) or appear as elongated cylinders or rods (longulites, belonites, baculites). When sufficiently large to be recognizable as mineral species (microlites) they can usually be classified as feldspar, pyroxene, amphibole or iron oxides. Acicular or needlelike microlites bearing divergent arborescent branches are termed scopulites.

The pitchstones of Arran are known for the variety and beauty of their crystallite and microlite constituents (amphibole). In the basaltic glasses of the Hawaiian Islands similar growths are formed of pyroxene.

**CRYSTALLIZATION**, the art of obtaining a substance in the form of crystals. It is an important process in chemistry, since it permits the purification of a substance or the separation of the constituents of a mixture. Generally a substance is more soluble in a solvent at a high temperature than at a low one, and consequently, if a boiling strong solution be allowed to cool, the substance will separate in virtue of the diminished solubility. The slower the cooling the larger and more perfect will be the crystals formed.

If, as sometimes occurs, such a solution refuses to crystallize, the expedient of "inoculating" the solution with a minute crystal of the same substance, or with a similar substance, may be adopted; shaking the solution or adding a drop of another solvent may also occasion the desired result. "Fractional crystallization" consists in repeatedly partially crystallizing the salt content of a solution so as to separate the substances of different solubilities.

Crystallization is also an important process in mineralogy. Most minerals are the product of crystallization, formed by the solidification of an element, compound or mixture under favourable conditions from a molten, liquid or gaseous state, or by solid-state crystallization. The process may be incomplete, as in crystal-

lite (*q.v.*), or the product of solidification may be noncrystalline, as in glass (*q.v.*). For discussion of crystallization and crystallization processes see **PETROLOGY**, especially the section on *Petrographical Provinces*. See also **GEOCHEMISTRY**: *Geochemistry of the Lithosphere*; **MINERALOGY**; **SEDIMENTARY ROCKS**. For specific information the reader is referred to the separate articles on kinds of rocks, such as **DOLOMITE** and **SCHIST**, and on mineral species, such as **QUARTZ**, and on groups, such as **FELDSPAR**.

A special application of crystallization is to be found in the manufacture of artificial rubies and other gem stones, primarily by a flame-fusion process developed by A. Verneuil (see **GEM**: *Synthetic Gems*). The study of crystals and crystallization is a special field dealt with in the article **CRYSTALLOGRAPHY**.

**CRYSTALLOGRAPHY**. Matter exists in three main varieties—the gaseous state, the liquid state and the solid state. Solid matter in which the atoms, molecules or ions are arranged in a regularly repeating pattern throughout is said to be crystalline; all other solid matter is said to be amorphous (noncrystalline), although the distinction is not always sharp. Practically all metals, minerals and alloys are crystalline, while glasses, plastics, ceramics and gels are amorphous. A single piece of crystalline matter is called a crystal. (In the electronics industry the word "crystal" is usually restricted in meaning to a crystalline substance that exhibits the piezoelectric effect; *e.g.*, quartz [see **PIEZOELECTRICITY**].) Crystallography is the science of crystals and of the crystalline state. Since most solid matter is crystalline, the properties of crystals are to a large extent also the properties of ordinary solid materials.

The topics discussed in this article are outlined below. A number of these topics involve some rather difficult concepts, and the reader who possesses no knowledge of solid state physics (*q.v.*) would be well advised to read that article first. The optical properties of crystals are treated in detail in the final section of the present article; other physical properties and related information on crystal science are covered elsewhere (see **ALLOYS**; **CRYSTALS**; **DISLOCATIONS OF**; **ELASTICITY**; **ELECTRICITY**; **CONDUCTION OF**; *Conduction in Solids*; **HEAT**; *Conduction of Heat in Solids*; **INTERMETALLIC COMPOUNDS**; **LUMINESCENCE**; **MAGNETISM**; **METALLURGY**; **METAL**; **MINERALOGY**; **X-RAYS**).

## I. INTRODUCTION

The feature that distinguishes matter in the crystalline state from the same matter in the liquid or gaseous state is that in the crystalline state matter is ordered in a certain geometrical way, while in the liquid and gaseous states it lacks this order. The crystalline state is thus the ordered state of matter—a fact which endows it with special properties that are of utmost importance in physics, chemistry, mineralogy, metallurgy and even in biology.

Crystallography may be said to have made a start as a science in 1669 when the Danish physician Nicolaus Steno discovered that, although quartz crystals may differ in appearance from one another, the angles between corresponding faces are always the same. Steno's findings were confirmed in 1772 by J. B. L. Romé de Lisle, who further noted that these interfacial angles are characteristic of the substance. In 1774 René Just Haüy published the book *Essai d'une théorie sur la structure des cristaux*, in which he showed that the known interfacial angles of crystals could be accounted for if the crystal were made up of units which correspond to the present-day unit cells. He explained not only crystal faces but also symmetry and cleavage on this basis. Because Haüy proposed this essentially correct basis of crystal structure, he is usually regarded as the father of crystallography.

Few fields of science changed more in the first half of the 20th century than did crystallography, and none so extended the range of its application. Before 1912, when Max von Laue's discovery of X-ray diffraction provided the key to the inner structure of crystals, virtually nothing was known of the arrangements of atoms in solid matter. The methods of chemistry could be applied to solids only after the solids had been melted, vaporized or brought into solution. Even the science of crystallography itself had not progressed farther than measuring and registering the external faces of crystals. Its function was mainly that of identifying and classifying minerals, and crystallography was regarded as a branch of mineralogy. Knowledge of the properties of solids was a matter of practical testing without a clue as to the underlying reasons and therefore without the possibility of changing the properties except by repeated variations and trials. Sir Arthur Eddington could remark quite truly in 1927 that more was known about the interior of a star than about the interior of a table.

Later the situation was entirely transformed. As a result of new diffraction methods it became possible to determine the molecular structure of any kind of solid, whether crystalline or not, and even to determine something of the structure of liquids. The results of these analyses, begun by Sir William H. Bragg and his son Sir Lawrence Bragg, and carried on by armies of research workers in nearly every country in the world, soon had the effect of transforming many of the ideas of chemistry and mineralogy and notably influencing geology and biology. In industry the practical applications were quite as marked, particularly in metallurgy, where X-ray diffraction became as essential a tool as the microscope, and in the new industries of artificial fibres and plastics. Indeed, as there is practically no industry where the properties of solids does not play a part, the range of utility of the new crystallography, after it had shown its powers in practice, rapidly increased.

The knowledge of the precise ways atoms are arranged in crystals—their distance apart, the form of the regular geometrical patterns they make in space—gave many new qualitative and quantitative data to chemistry. The sizes of the different atoms and the lengths of the bonds joining them were revealed. The new crystallography furnished a microscope which, in competent hands, could discern molecules, atoms and even the distribution of electrons. These data were a valuable adjunct to the quantum theory in the reinterpretation of chemical formulas and in the establishment of new ones. Inorganic chemistry—the chemistry of acids, bases and salts—was largely rewritten in terms of ions (electrically charged atoms). The complexities of mineral chemistry, particularly of the silicates (which constitute the bulk of the earth's crust), were unraveled as a result of crystallography. The science of geochemistry, which offers clues to the distribution of minerals in the earth, was largely built on a basis of crystal structures.

Even greater was the contribution of crystallography to metallurgy. The composition of metals and alloys seemed to defy all the rules of chemistry. New rules were found for their composition in terms of relatively simple crystal structures. These same structures explained for the first time the plastic properties of metals that enable them to be rolled and drawn, as well as the inner mechanism of many age-old processes such as annealing and tempering.

In biology, X-ray techniques revealed the fine structures of tissues which were beyond the range of the optical microscope or even of the electron microscope. Although these studies are extremely complex, already much is known of the structure of hard tissues—cell walls, hair, skin and tendons—and a start has been made on the major problem of protein structure.

## II. TRANSLATIONAL ORDER IN CRYSTALS

A pure chemical substance can be regarded as made up of an aggregate of chemical units of the same kind. In some cases, especially in organic compounds, these units are molecules. From this point of view, every pure chemical substance can be regarded as a collection of copies of some model cluster of atoms. These copies have no special geometrical order in the gaseous or liquid state, but in the crystalline state the copies are arranged in space as if all were derived from some arbitrarily chosen model cluster by a simple geometrical operation repeated again and again. While crystals of various substances differ among themselves as to which geometrical operations appear to repeat the cluster, they all have in common one simple type of repetition; namely, periodic repetition by translations. An example of this kind of repetition, using an arbitrary motif, is shown in fig. 1(A). It is evident that

FROM M. J. BUEBBER, "ELEMENTARY CRYSTALLOGRAPHY", REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.

FIG. 1.—(A) PATTERN PRODUCED BY PERIODIC REPETITION IN THREE DIMENSIONS AND DEFINED BY TRANSLATIONS  $t_1$ ,  $t_2$  AND  $t_3$ ; (B) THREE-DIMENSIONAL LATTICE OF PATTERN IN (A)

fig. 1(A) shows a periodic pattern in which the motif is a comma. All commas can be thought of as copies of any particular comma, which may be arbitrarily regarded as the original model for all others. If this view is adopted, any comma may be thought of as derived from the original model by moving it to new locations, making repeated use only of the three translations  $t_1$ ,  $t_2$  and  $t_3$ , which can be regarded as vectors. Thus, if the comma at the lower left-hand forward point is regarded as the original prototype, any comma in the lower forward row can be thought of as derived from it by using a translation

$$\mathbf{T} = u\mathbf{t}_1 \quad (1)$$

where  $t_1$  is the vector shown in the diagram, and  $u$  is an integer. By generalization, any comma at any position in the pattern can be derived from the lower left-hand forward one by application of a translation  $\mathbf{T}$  having components given by

$$\mathbf{T} = u\mathbf{t}_1 + v\mathbf{t}_2 + w\mathbf{t}_3 \quad (2)$$

where  $u$ ,  $v$  and  $w$  are appropriate integers.

**1. Lattices and Cells.**—All crystals have at least this kind of order, which can be described as a periodic repetition of their atomic chemical motif by translations. It is convenient to divorce this kind of repetition from the nature of the motif. This can be done by representing the motif by a point. With this simplification, the chief characteristic of the repetition can be represented by a collection of points repeated from some original point.

This is illustrated in fig. 1(B). This collection of periodically translated points is called a lattice, or sometimes, more specifically, a space lattice if the translations embrace three dimensions, as in (2). A lattice is a collection of periodically translated points; it is a shorthand way of representing and visualizing periodic repetition by translation. Given a lattice, if any motif is imagined as placed at a lattice point, the motif appears in a corresponding position at all lattice points, and in the same orientation.

The three translations,  $t_1$ ,  $t_2$  and  $t_3$ , of (2) and fig. 1 determine three edges of a parallelepiped. This parallelepiped has a volume which contains one motif (or its equivalent). The parallelepiped, including its contained motif, is repeated by the lattice to become the entire crystal. The parallelepiped is called a *cell*, in particular a *primitive cell*, because it contains the volume of one motif which, repeated by the translations, reproduces the crystal. Multiple cells, which contain several motifs, can also be defined, and such cells are useful in certain cases to be noted later.

**2. Indices of Points, Lines and Planes.**—The edges of the cell constitute an excellent co-ordinate system for describing the geometry of the crystal. Any point in the lattice can be reached by the translations described by (2). A lattice point is said to have indices  $u v w$ . Since three integers are used for many kinds of representation in crystallography, the indices of a point may be distinguished by placing them between centred dots; thus,  $u \cdot v \cdot w$  (for example,  $\cdot 153 \cdot$ ).

The line which runs from the origin to a point  $u v w$  fixes a direction in a crystal. The three integers in (2) uniquely define the direction of  $T$ , and are called the indices of the direction. To distinguish the indices of a direction from other indices, the former are enclosed in brackets, thus,  $[u v w]$ ; for example,  $[153]$  is the direction from the origin,  $\cdot 000 \cdot$ , to the point  $\cdot 153 \cdot$ .

A plane can also be represented by three indices. These are placed between parentheses, thus,  $(hkl)$ ; for example,  $(123)$ . The indices of a plane, called the Miller indices after William Hallows Miller (1839), are derived from the intercept form of the equation of a plane. In particular, the equation of a plane can be written

$$\frac{x}{1/h} + \frac{y}{1/k} + \frac{z}{1/l} = 1 \quad (3)$$

The denominators on the left of (3) are the intercepts of the plane. The plane evidently intercepts the axes of  $x$ ,  $y$  and  $z$  at  $1/h$ ,  $1/k$  and  $1/l$  units; that is, it cuts the unit of  $x$  into  $h$  parts, the unit of  $y$  into  $k$  parts, and the unit of  $z$  into  $l$  parts. The directions and units of  $x$ ,  $y$  and  $z$  are the edges  $t_1$ ,  $t_2$  and  $t_3$ , respectively, of the cell.

**3. Rational and Irrational Geometrical Features.**—Geometrical features of a crystal which are defined by lattice points are said to be rational. Thus, in (2), if  $u$ ,  $v$  and  $w$  are integers, the point  $uvw$  is a lattice point, and the direction  $[uvw]$  not only starts at the origin lattice point  $\cdot 000 \cdot$  but extends to the lattice point  $uvw$ . It therefore encounters lattice points periodically at intervals  $T$  of (2). Similarly it can be shown that the plane  $(hkl)$  contains lattice points periodically arranged on its surface if  $h$ ,  $k$  and  $l$  are integers. Geometrical features that are not so defined by lattice points are said to be irrational. Thus, if a point, line or plane contains no lattice point, it is irrational. A line or plane is also irrational if it contains only one lattice point, and a plane is also irrational if it contains only one line of lattice points.

### III. ROTATIONAL ORDER IN CRYSTALS

It was seen above that a motif can be repeated by translation to form a periodic pattern. It can also be repeated to form another kind of periodic pattern by rotating it about an axis, and repeating it periodically after turning through some angle, as

FROM M. J. BUEGER, "ELEMENTARY CRYSTALLOGRAPHY" REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.

FIG. 2.—REpetition BY A PERIODICALLY REPEATED ROTATION THROUGH ANGLE  $\alpha$  ABOUT AXIS A

shown in fig. 2. This repetition is obviously cyclical, and its end must coincide with the beginning. This restricts the angular period of  $2\pi/n$ , where  $n$  is an integer. Furthermore, it is found that, when the requirements of translational repetition are considered in connection with angular repetition, the angular frequency  $n$ , per cycle, is restricted to 1, 2, 3, 4 and 6.

**1. Symmetry.**—The whole set of  $n$  features comprises an  $n$ -fold repetition of the same feature. The set is said to be symmetrical with respect to an  $n$ -fold axis of symmetry. The conclusions of the preceding section can be restated thus: only 1-fold, 2-fold, 3-fold, 4-fold and 6-fold axes of symmetry are permitted to crystals. In writing, these kinds of axes are recognized by the labels 1, 2, 3, 4 and 6, respectively. In illustrations, the trivial 1-fold axis is not represented by a symbol, but the others are represented by the following symbols placed normal to the axis:

2-fold:  $\bigcirc$   
3-fold:  $\triangle$   
4-fold:  $\square$   
6-fold:  $\bigcirc$

These cases of pure angular symmetry are called proper rotation

FIG. 3.—(A) PLAN VIEW OF THE REPETITIONS OF A COMMA BY AXES OF 1-, 2-, 3-, 4- AND 6-FOLD SYMMETRY; (B) PLAN VIEW OF THE REPETITIONS OF A COMMA BY AXES OF 1-, 2-, 3-, 4- AND 6-FOLD SYMMETRY. SHADED COMMAS ARE ABOVE PLANE OF THE PAGE, UNSHADED ONES ARE AN EQUAL DISTANCE BELOW

axes, and are illustrated in fig. 3.

A general name for a geometrical feature which describes the symmetry of an object is symmetry element. The proper rotation axes are examples of symmetry elements, as also are the mirror, the inversion centre and the improper rotation axes introduced below.

**2. Enantiomorphous Objects.**—In three-dimensional space, an unsymmetrical geometrical object can assume two related shapes, ordinarily called right-handed (dextro) and left-handed (levo) shapes. These two shapes are said to be enantiomorphous with each other, and each is an enantiomorph of the other (see STEREOCHEMISTRY: General Discussion of Stereoisomerism). In three-dimensional space, two enantiomorphous shapes can be transformed into one another in only two distinct ways:

1. Reflection in a mirror (fig. 4[A]). For example, let the co-

FIG. 4.—(A) REPETITION BY REFLECTION IN A MIRROR; (B) REPETITION BY INVERSION THROUGH A CENTRE

ordinates  $x$  and  $z$  be taken in the mirror, and the co-ordinate  $y$  be taken normal to it. Then if a point has co-ordinates  $xyz$  in one enantiomorph, the corresponding point has co-ordinates  $x\bar{y}z$  in the other, where  $\bar{y}$  is a crystallographic convention for  $-y$ .

2. Inversion through a point (fig. 4[B]). For example, let one enantiomorph be referred to a co-ordinate system with the origin at the point of inversion. Then if the co-ordinates of a point in one enantiomorph are  $xyz$ , the co-ordinates of the corresponding point in the other are  $\bar{x}\bar{y}\bar{z}$ .

3. Axes of Improper Symmetry.—If some unsymmetrical object (which may arbitrarily be designated right-handed) is taken as an original motif, repetition of it can be either of the type RRRRRR . . . or of the type RLRLRL . . . (R and L are abbreviations for "right" and "left"), and in both cases the repetition can be regarded as periodic. If the repetition is angular, the objects RRRR . . . are related by a proper rotation axis, discussed above. If the sequence is RLRL . . ., the objects are said to be related by an improper rotation axis. An improper axis,  $\bar{n}$ , can be described as a rotation through  $2\pi/n$  (to produce the rotation) combined with an inversion through the centre of the co-ordinate system. Repetition by proper and improper rotation axes is illustrated in fig. 3. The axis labeled  $\bar{n}$  is said to be an  $n$ -fold rotoinversion axis.

It can be readily demonstrated that, when  $n$  is odd, an axis  $\bar{n}$  can be decomposed into two other symmetry elements, namely, an  $n$ -fold rotation axis plus an inversion centre. When  $n$  is even but not divisible by 4, an axis  $\bar{n}$  can be decomposed into an  $n/2$ -fold rotation axis plus a perpendicular mirror,  $m$ . But when  $n$  is divisible by 4, an axis  $\bar{n}$  cannot be decomposed into simpler symmetry elements.

#### 4. Angular Combinations of Rotation Axes.

—An initial motif can evidently be repeated by an  $n$ -fold axis  $A$ , as already discussed. It can simultaneously be repeated by another axis  $B$ , which makes an angle with  $A$ , as shown in fig. 5. But the illustration shows that a rotation about  $A$  followed by a rotation about  $B$  is equivalent to a rotation about some third axis  $C$ . If the angular periods about  $A$ ,  $B$  and  $C$  are  $\alpha$ ,  $\beta$  and  $\gamma$  respectively, the angle  $A \wedge B$  is given by

$$\cos A \wedge B = \frac{\cos \frac{\gamma}{2} + \cos \frac{\alpha}{2} + \cos \frac{\beta}{2}}{\sin \frac{\alpha}{2} \sin \frac{\beta}{2}} \quad (4)$$

FIG. 8.—THE SIX PERMISSIBLE NONTRIVIAL CRYSTALLOGRAPHIC COMBINATIONS OF ROTATIONS

FROM M. J. BUEGER, "ELEMENTARY CRYSTALLOGRAPHY"; REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.

FIG. 7.—THE SIX CRYSTALLOGRAPHIC AXIAL SYMMETRIES BASED UPON THE COMBINATIONS IN FIG. 6

Now for crystals,  $\alpha$ ,  $\beta$  and  $\gamma$  can only be  $2\pi/n$ , where  $n$  is 1, 2, 3, 4 or 6, as noted previously. If all these values are used systematically in (4), only six distinct nontrivial solutions are found. These are shown in fig. 6. When each of the axes in fig. 6 is allowed to repeat the others, the six sets of axes shown in fig. 7 are formed. If all rotational symmetries are tabulated, they are shown to contain the 11 combinations of axes given in Table I. It will be noted that there are two different combinations containing only 2-fold and 3-fold axes. In the customary label for the combination 322, the second 2 is omitted, giving 32, because it turns out that in this kind of combination the first and second 2 are transformed into one another by the other (odd-fold) axis. In the other combination, a somewhat similar degeneracy occurs, leaving only two symbols. The two combinations are conventionally distinguished by the order of the symbols, 32 and 23.

TABLE I.—Possible Crystallographic Symmetries With Respect to Proper Rotation Axes

Uncombined axes	Permissible combinations
1	2 2 2
2	3 2 2 (called 3 2)
3	4 2 2
4	6 2 2
6	2 3 3 (called 2 3)
	4 3 2

If improper axes are permitted in combinations such as discussed above, it can be readily shown that the only permissible simple combinations are those which contain an even number of improper axes. The only permissible combinations therefore conform to the type PPP (already discussed), PII, IPI or IIP (where P stands for a proper rotation axis and I for an improper one). Furthermore, a proper and improper axis of the same frequency  $n$  may be parallel: the symbol for this is written as a fraction, namely,  $\frac{n}{\bar{n}}$ . If all these combinations are examined, the 21 new permissible combinations shown in Table II are found.

5. The 32 Crystal Classes.—Table I lists the 11 symmetries involving only repetitions that are permissible to crystals not having enantiomorphous features; Table II lists the additional 21 symmetries permissible to crystals with enantiomorphous features. These 11 + 21 = 32 symmetries are the only ones permitted to crystals in which rotational symmetries are involved. In 1830 Johann Friedrich Christian Hessel proved that crystals could have 32 kinds of symmetry, although only a few of these symmetries had been observed at that time.

Although these 32 symmetries constitute an intermediate result of symmetry theory, they are valuable in classifying crystals. The reason for this is that, while crystals contain translational repetitions as well as rotational ones, the translations are too small to be seen by eye. On the other hand, rotational symmetries are observable in the external appearances of crystals, as noted in

TABLE II.—Permissible Crystallographic Symmetries Involving Improper Rotation Axes

Uncombined axes	Combinations conforming to the type:				
	$\frac{p}{q}$	PII	IPI	IIP	PPP III
$\bar{1}$	$\left(\frac{1}{1} = \bar{1}\right)$				
$\bar{2} = m$	$\frac{2}{2} = \frac{2}{m}$	$2\bar{2}\bar{2} = 2mm$			$\frac{2}{2}\frac{2}{2}\frac{2}{2} = \frac{2}{m}\frac{2}{m}\frac{2}{m}$
$\bar{3}$	$\left(\frac{3}{3} = \bar{3}\right)$	$3\bar{2}(\bar{2}) = 3m$			$\frac{3}{3}\frac{2}{2}\left(\frac{2}{2}\right) = \frac{2}{3}\frac{2}{m}$
$\bar{4}$	$\frac{4}{4} = \frac{4}{m}$	$4\bar{2}\bar{2} = 4mm$	$\bar{4}22 = \bar{4}2m$		$\frac{4}{4}\frac{2}{2}\frac{2}{2} = \frac{4}{m}\frac{2}{m}\frac{2}{m}$
$\bar{6}$	$\frac{6}{6} = \frac{6}{m}$	$6\bar{2}\bar{2} = 6mm$	$\bar{6}2\bar{2} = \bar{6}2m$		$\frac{6}{6}\frac{2}{2}\frac{2}{2} = \frac{6}{m}\frac{2}{m}\frac{2}{m}$
		$2\bar{3}(\bar{3}) \rightarrow 2\frac{3}{2} \rightarrow \frac{2}{3}$			$\left(\frac{2}{2}\frac{3}{3}\left(\frac{3}{3}\right) = \frac{2}{m}\frac{3}{m}\right)$
		$4\bar{3}\bar{2} = 4\frac{3}{2}\frac{2}{2} \rightarrow \frac{4}{3}\frac{2}{m}$	$\bar{4}3\bar{2} = \bar{4}3m$	$\left(\bar{4}\bar{3}2 \rightarrow \bar{4}\frac{3}{2}m = \frac{4}{m}\frac{3}{m}\frac{2}{m}\right)$	

some detail below. Therefore the 32 rotational symmetries of crystals comprise a natural classification for the visible appearance of crystals, and hence are often called the 32 crystal classes. These symmetries can be studied by the mathematical theory of groups, and in this connotation they are referred to as the 32 point groups. The "point" in this nomenclature is the intersection of all the axes, which, because it is on each and every axis, is not repeated by the axis. These are thus the 32 crystallographic symmetries about a point.

TABLE III.—The 32 Crystallographic Point Symmetries (International Symbols)

Triclinic	Monoclinic	Tetragonal		Hexagonal	Isometric
1 $\bar{1}$	2 (2 = ) m $\frac{2}{m}$	3 $\left(\frac{3}{3} = \bar{6}\right)$	4 $\frac{4}{m}$	6 $\frac{6}{m}$	
	Orthorhombic 2 2 2 2mm $\frac{2}{m}\frac{2}{m}\frac{2}{m}$	3 2 3m $\frac{3}{2}\frac{2}{m}$	4 2 2 4mm $\bar{4}2m$ $\frac{4}{m}\frac{2}{m}\frac{2}{m}$	6 2 2 6mm $\bar{6}2m$ $\frac{6}{m}\frac{2}{m}\frac{2}{m}$	2 3, 4 3 2 $\bar{4}3m$ $\frac{2}{m}\frac{3}{m}\frac{4}{m}\frac{3}{m}\frac{2}{m}$

The 32 crystallographic point symmetries of Tables I and II are shown in a different arrangement in Table III. Table IV shows an alternative set of symbols, known as the Schoenflies symbols, for the point groups. The Schoenflies notation is commonly employed in molecular spectroscopy.

#### IV. SYMMETRY-SPECIALIZED SPACE LATTICES

It has already been noted that the presence of translational repetition in crystals limits the angular repetitions to rotation axes with frequencies 1, 2, 3, 4 and 6. Conversely, these axes and their combinations restrict the translations to certain specialized types of space lattices. These were first investigated in 1842 by M. L. Frankenheim, who found 15 types. In 1850 Auguste Bravais investigated them more rigorously and showed that there are only 14 types. These 14 space lattices are commonly referred to as the Bravais space lattices.

The general nature of the deduction of these lattice types is as follows. In fig. 1(B) it is evident that any space lattice can be regarded as a periodic repetition by a translation  $t_3$  of two-dimensional lattice whose translation repetitions are  $t_1$  and  $t_2$ . Thus a space lattice is a stack of plane lattices whose periodic displacement is  $t_3$ . Now suppose that it is desired to deduce the

space-lattice types consistent with a 4-fold axis. The plane lattice perpendicular to the 4-fold axis must have points arranged on the corners of a square; that is, it can be referred to a square cell. But the square-celled lattice is consistent with a perpendicular 4-fold axis either through a cell vertex or through a cell centre. The first and second layers of the space lattice can be pierced by the 4-fold axis in the same place (fig. 8[A]), or one can be pierced through a cell vertex and the other through a cell centre (fig. 9[A]). The first alternative has  $t_3$  perpendicular to the plane of  $t_1$  and  $t_2$ , giving rise to a space lattice where the cell is a square prism (fig. 8[B]). In the second alternative, the displacement  $t_3'$  projects on one plane as  $\frac{1}{2}t_1 +$

$\frac{1}{2}t_2$ . If the cell based upon  $t_1$ ,  $t_2$  and  $t_3'$  were accepted, it would have  $t_3'$  oblique to the plane of  $t_1$  and  $t_2$ , and the cell itself would not have 4-fold symmetry. A cell which has not only 4-fold symmetry but also orthogonal axes can be arranged by choosing a new  $t_3$  such that

$$t_3 = -t_1 - t_2 + 2t_3 \quad (5)$$

Because of the geometrical advantage of orthogonality, the cell based upon these new edges (fig. 9[B]) is always chosen. But with this advantage goes the disadvantage that this cell has a lattice point on the centre of the "unit" cell. Therefore the cell is not primitive because it has two lattice points associated with it; it is a double cell.

The preceding discussion has been concerned with the kinds of space lattices consistent specifically with a 4-fold axis. A similar discussion can be given for every symmetry. When this is done, it is found that many symmetries permit more than one kind of lattice.

Every symmetry can be represented by a lattice in which the primitive cell has the symmetry of the lattice. Such lattices and cells are designated P (for "primitive"). In addition, many symmetries can be represented by another lattice whose primitive cell has less symmetry than the lattice. But in such cases a multiple cell can be chosen which does have the symmetry of the lattice. The various possibilities of lattices with multiple cells are shown in Table V.

A further consequence of investigating the various lattice types consistent with each symmetry is that it is found that several symmetries are consistent with exactly the same lattice types. For example, symmetry  $\bar{1}$  requires the same lattice as symmetry 1, because all lattices are inherently centrosymmetrical (that is, for

TABLE IV.—The 32 Crystallographic Point Symmetries (Schoenflies Symbols)

	Orthorhombic $D_2$ $C_{2v}$ $D_{2h}$	$D_4$ $C_{4v}$ $D_{2d}$ $D_{4h}$	$D_4$ $C_{4v}$ $D_{2d}$ $D_{4h}$	$D_6$ $C_{6v}$ $D_{3h}$ $D_{6h}$	$T$ $O$  $T_d$  $T_h$ $O_h$

TABLE V.—The General Kinds (or "Modes") of Space Lattices

Multiplicity of cell	Label	Lattice Requirements
Single	P	Primitive cell must have symmetry of lattice
Double	I	Body-centred cell must display symmetry of lattice
	A	Cell centred on <i>A</i> or (100) face must have symmetry of lattice
	B	Cell centred on <i>B</i> or (010) face must display symmetry of lattice
Quadruple	C	Cell centred on <i>C</i> or (001) face must display symmetry of lattice
	F	Cell centred on all faces <i>A</i> , <i>B</i> and <i>C</i> must have symmetry of lattice
Single (Triple)	R	Primitive cell must have shape of rhombohedron (This lattice is more conveniently referred to a cell with $a=b \neq c$ , $\beta=120^\circ$ , but having two internal points spaced $\frac{1}{3}$ and $\frac{2}{3}$ along the long body diagonal)

every translation  $t$  in a lattice, there exists the reverse translation  $t$ ).

The distribution of these general types among the different symmetries is shown in Table VI. This tabulation calls for the following remarks. In the second line, I, A and B are not distinct but merely represent alternative permissible ways of selecting a cell from the lattice points. In the third line, A, B and C are not distinct but merely represent the orientation selected for the centred cell. Finally, it will be observed that P for the 3-fold case and the P lattice for the 6-fold case have the same symmetry, as noted in the third column; therefore these two cases give the same lattice type. Taking these duplications into account, there are 14 distinct specialized space-lattice types. A unit cell of each lattice type is shown in fig. 10.

## V. CRYSTALLOGRAPHIC CO-ORDINATE SYSTEMS

The edges of the unit cell of the lattice provide the units of the natural co-ordinate system of the crystal. It should be noted that in Table VI the P lattices for 3- and 6-fold axes are the same, and that in Table V the R lattice can be referred to a cell of the same external shape as P for 3- and 6-fold axes, but having two additional internal lattice points. If these two lattices are referred to the same cell edges, it can be seen that only six symmetrically distinct co-ordinate systems are required for

crystals. These are called the six crystal systems. (Some authors distinguish, in different ways, a subdivision of the hexagonal system, calling it "trigonal" or "rhombohedral." Such practices lead to serious inconsistencies and should be avoided.)

Both the 32 symmetries permitted to crystals, and the 6 co-ordinate systems to which crystals can be referred, constitute ways of classifying crystals. It should be observed that the most fundamental classification is that based upon the 32 symmetries. The significance of the crystal systems can be overestimated, and the restrictions they place upon crystals are frequently misunderstood by beginners. Basically, the six crystal systems provide six convenient co-ordinate systems to which to refer the geometry of crystals. Each crystal system, shown in the fourth column of Table VI, embraces several symmetries, as shown in the first column of that table.

**1. Axes of Systems.**—Thus far, the translations of the unit cell have been labeled  $t_1$ ,  $t_2$  and  $t_3$ , to stress the fact that these are translations of the lattice. Crystallographers designate the cell edges as  $a$ ,  $b$  and  $c$ . These correspond to the units along the  $X$ ,  $Y$  and  $Z$  axes to be used as the co-ordinate systems for the crystals. The angles between the  $a$ ,  $b$  and  $c$  axes are labeled thus:

$$\begin{aligned}\text{angle } a \wedge b &= \gamma \\ \text{angle } b \wedge c &= \alpha \\ \text{angle } c \wedge a &= \beta\end{aligned}$$

Symmetry causes the lengths of  $a$ ,  $b$  and  $c$  and the angles between them to be specialized. This specialization is listed in the last column of Table VI. The information contained in that column is so frequently subject to misinterpretation that an attempt is made here to avoid this. The sign  $=$  is the mathematical one for "is identically equal to," and implies that this is true under all circumstances. In this use, the equality is required by the symmetry (noted in the first column).

The sign  $\neq$  means "is not generally equal to." In the present use, it does not prevent the two quantities connected by the sign from being "accidentally" equal on occasion. Thus, in the orthorhombic case, the last column of Table VI describes the relation between the lengths of the axes as  $a \neq b \neq c$ . This means that, in general,  $a$ ,  $b$  and  $c$  are not required by symmetry to be identical. It should be emphasized that, although symmetry does not require identity, nothing prevents them from being equal within the precision of measurement. If, on measurement of the cell edges of a certain crystal, it turned out that  $a$  and  $b$  were, by some chance, equal within the precision of measurement, this would imply  $a = b$ , but not  $a = b$ . The finding that  $a = b$  dimensionally, therefore, does not place the crystal in the tetragonal system, for which the last column of Table VI gives  $a = b \neq c$ . More generally, it

FROM M. J. BUEHRER, "ELEMENTARY CRYSTALLOGRAPHY," REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.  
FIG. 8.—DERIVATION OF THE TETRAGONAL PRIMITIVE LATTICE

should be clearly understood that the descriptions of axial dimensions in the last column of Table VI are not definitions of the crystal systems; they are merely statements of dimensional restrictions in the crystal systems. On the contrary, the first column of Table VI shows that a crystal is tetragonal if and only if its symmetry contains one axis with  $n = 4$ . This requires that  $a \equiv b$ . (If the symmetry contained more than one axis with  $n = 4$ , the  $a \equiv b$  requirement would place the crystal in the isometric system, where the symmetry requires  $a \equiv b \equiv c$ .)

The specialization of axes required by symmetry, such as  $a \equiv b$ , implies that these axes cannot be distinguished. Under these circumstances they are called  $a_1$  and  $a_2$ , instead of  $a$  and  $b$ , etc.

By common agreement, crystals are ordinarily drawn in a conventional orientation. The convention requires first, that  $c$  be oriented in a vertical position with  $+c$  upward. Second,  $b$  is oriented approximately left and right (if  $\alpha = 90^\circ$ ,  $b$  becomes exactly horizontal), with  $+b$  to the observer's right. This leaves  $a$  oriented approximately toward and away from the observer; it is taken as  $+$  toward the observer. The resulting axial system is right-handed.

**2. Special Features of Systems.**—There follow some remarks about conventions and other special features of the several crystal systems.

**Isometric System.**—The three cell edges are orthogonal and equal, and, since they are indistinguishable, they are labeled  $a_1$ ,  $a_2$  and  $a_3$ . The axes therefore comprise the ordinary Cartesian coordinate system.

**Tetragonal System.**—The three cell edges are orthogonal, but two are indistinguishable and are called  $a_1$  and  $a_2$ . The (tetragonal) axis is unique and is labeled  $c$ . It is customarily oriented vertically.

FIG. 9.—DERIVATION OF THE TETRAGONAL BODY-CENTRED LATTICE

FIG. 10.—THE SIX CRYSTAL SYSTEMS AND THEIR INCLUDED SPACE-LATTICE TYPES

**Hexagonal System.**—One axis corresponds to the symmetry axis with  $n = 3$  (or 6). It is unique, labeled  $c$  and customarily oriented vertically. The other two axes are in a plane normal to  $c$ ; they make an angle  $\gamma = 120^\circ$  with each other, are indistinguishable and are called  $a_1$  and  $a_2$ . Neither  $a_1$  nor  $a_2$  can be distinguished from a third axis with which they form a set of three related by this 3-fold axis  $c$ . This unnecessary but inescapable axis is called  $a_3$ . The hexagonal system is customarily referred to four axes:  $a_1 \equiv a_2 \equiv a_3 \neq c$ . The indices of a plane with respect to these are, respectively,  $h$ ,  $k$ ,  $i$  and  $l$ . Because  $a_1$ ,  $a_2$  and  $a_3$  are linearly dependent in their plane, the integers  $h$ ,  $k$  and  $i$  are also dependent as follows:

$$h + k + i = 0 \quad (6)$$

The indices of a plane in the hexagonal system are written fully as  $(hki\bar{l})$  which, because of the linear dependence in (6), is often abbreviated  $(hkl)$ .

**Orthorhombic System.**—The three axes  $a$ ,  $b$  and  $c$  are distinct but orthogonal. By universal agreement they are labeled so that  $a < b$ . An earlier generation of crystallographers placed no restriction on the length of  $c$ ; however, it is desirable to describe newly measured crystals with the convention  $a \leq b < c$ . (Some crystallographers prefer  $c < a < b$ , which is much like defining 1, 2 and 3 such that  $3 < 1 < 2$ . No logic prevents this, but  $a < b < c$  requires a minimum of arbitrary ruling.)

**Monoclinic System.**—If the unique axis with  $n = 2$  is called  $c$  (as in the tetragonal system with unique axis  $n = 4$ , and the hexagonal system with unique axis  $n = 3$  or 6), the monoclinic system is said to be described in the *first setting*. In this setting the 2 or  $\bar{2}$  axis is called  $c$  and taken vertically, while the plane of  $a$  and  $b$  is orthogonal to  $c$ . The angle ( $\gamma = ab$ ) is taken as obtuse. (If described in the *second setting*,  $b$  is taken as the 2 or  $\bar{2}$  axis and set horizontally, and the plane of  $a$  and  $c$  is taken orthogonal to  $b$ . The second setting was usual with a past generation; however, it does not fit in with the principle of a minimum of arbitrary rulings, and therefore should be dropped.)

**Triclinic System.**—The three cell edges are entirely unspecialized in lengths and interaxial angles. Since there is no symmetrical specialization, there are an infinite number of ways in which the cell can be chosen from the lattice. By convention that cell is chosen which has for edges the three shortest noncoplanar edges. This cell is called the reduced cell. Such cells occur in two types: one can be described by a set of three edges surrounding a corner with three acute angles, the other by a set of three edges surrounding a corner with three obtuse angles. These are called all-acute cells or type-I cells, and all-obtuse cells or type-II cells, respectively.

All crystallographers agree with the convention of labeling the cell edges to conform with  $a < b$ . For reasons mentioned in the discussion of orthorhombic crystals above, it is desirable to describe newly measured crystals with the additional restriction  $a < b < c$ .

## VI. APPLICATIONS OF POINT SYMMETRY

Under appropriate circumstances a crystal may extend its boundaries, or "grow." If allowed to grow by the addition of atoms or clusters of atoms to its free surface, this exterior surface comes to be made up of a set of plane surfaces which prove to be rational lattice planes. Without inquiring at this point why this is so, the information can be combined with the geometrical theory presented up to this point to give useful results.

**1. Crystal Forms.**—If the crystal grows in an environment of radial symmetry, that is, if the environment is the same in all directions, the symmetry of the crystal surface is limited only by the symmetry of the crystal pattern. For example, suppose that the crystal pattern has symmetry 4 (neglecting translations), and suppose that in growing the crystal develops a plane surface, say (100), parallel to the 4-fold axis of the pattern (fig. 11). Then the 4-fold symmetry requires that the crystal be identical along four planes like (100) and separated from the plane (100) by rotations of  $90^\circ$ ,  $180^\circ$  and  $270^\circ$ . These additional planes have indices (010),  $(\bar{1}00)$  and  $(0\bar{1}0)$ , respectively. The four planes

(100), (010), (100) and (010) comprise a symmetrical set with respect to the 4-fold axis. If one plane advances by growth, so must all four, because they are the same. Conversely, this set of four surface planes reveals that the pattern of the crystal contains a 4-fold axis.

A symmetrical set of planes is called a form. This designation is not a synonym for "shape" but has a technical significance. A form is symbolized by the index of any one of its faces, usually one with all positive indices. If the index of the plane is  $(hkl)$ , the index of the corresponding form is written  $\{hkl\}$ , or less preferably  $\{hkl\}$ . The form  $\{hkl\}$  can be regarded as the face  $(hkl)$  repeated or multiplied by the symmetry. Common forms tend to have indices composed of small integers, of which 0 and 1 are usual.

In nearly all cases a form with general indices  $\{hkl\}$  has a different shape for each symmetry. On the other hand a form with specialized indices may be the same for several symmetries. For example,  $\{100\}$  is the same form, a cube, for the five isometric symmetries 23, 432,  $2/m\bar{3}$ , 432 and  $4/m\bar{3}2/m$ .

A crystal grown in free space normally is a polyhedron of rational plane faces, and this polyhedron can be resolved into a set of forms. Certain forms, like the cube, are known as closed forms because such a form can enclose space. Other forms are known as open forms because one cannot enclose space and can only appear on a crystal combined with other forms. There are a total of 47 different crystal forms. The occurrence of these among the point symmetries is shown in Tables VII, VIII, IX and X.

**2. Dissolution of Crystals.**—When a crystal is placed in contact with a solvent, it dissolves in such a way as to be consistent with its symmetry. For example, if a sphere is cut from a quartz crystal and if this sphere is permitted to be partly dissolved by hydrofluoric acid, the resulting shape has the symmetry of quartz, namely 32. An example is shown in fig. 12. This is known as a dissolution form.

If the solvent is weak, or permitted to act only briefly, it is often observed that it attacks the crystal at a number of isolated

points, producing minute pits, called etch pits, at these points. The shape of such a pit is consistent with the symmetry of the crystal at that point, and etch pits can therefore be used to reveal the symmetry of the crystal. For example, the cube,  $\{100\}$ , is consistent with all five isometric symmetries, but if a crystal whose surface is a cube is etched, it should show a symmetry of shape and placement consistent with one of the five in fig. 13.

## VII. DETAILED SYMMETRY OF CRYSTALS

**1. Combination Symmetries.**—In introducing the notion of order in crystals it was noted that a crystal can be thought of as an aggregate of atom clusters, the clusters all being periodic repetitions of some particular cluster which may be regarded as the motif. Repetition can be defined by translation, by rotation and by reflection, and these simple repetition schemes have already been considered. But periodic repetitions can also be achieved by periodic application of appropriate combinations of these simple repetition devices.

**2. Screw Axes.**—Periodic repetition by a rotation-translation can be referred to a symmetry element called a screw axis, in which the rotation component is the  $n$  of the rotation axis, and the translation compo-

FIG. 12.—DISSOLUTION FORM RESULTING FROM ETCHING A QUARTZ SPHERE WITH HYDROFLUORIC ACID

THE DISSOLUTION FORM SHOWS SYMMETRY 32

ment  $\tau$  is the pitch of the screw. If a point is repeated periodically by screw motion, the repetition must eventually bring the repeated point to translation equivalence with the original point in order that the collection of points may have the pure translational order characteristic of all crystals. This condition restricts the possible kinds of screw axes by requiring that  $n\tau = mt$ , so that  $\tau = (m/n)t$ , where  $m$  is an integer and  $t$  is one of the translations of the lattice. A screw axis is designated by the frequency of the axis,  $n$ , and the frequency of the pitch,  $m$ , in the form  $n_m$ . The possible values of  $n$  and  $m$  give rise to the screw axes shown in fig. 14; the manner in which the screw axes repeat a point is also shown in this figure.

**3. Glide Planes.** Periodic repetition by a reflection-translation can be referred to a symmetry element called a glide plane, in which the translation component is  $\tau$  and the reflection component is  $m$ . This is illustrated in fig. 15. Glide planes are restricted by the requirement that  $2\tau = t$ . A glide plane is labeled according to the lattice translation  $t$  to which the translation component  $\tau$  is parallel. These designations are shown in Table XI.

**4. Space Groups.**—In the same general way that the possible

FIG. 14.—THE REPETITION OF A POINT BY THE POSSIBLE CRYSTALLOGRAPHIC SCREW AXES

rotation and rotoinversion axes can be combined, combinations can be formed which include screw axes, glide planes and translations (that is, the lattices). When these combinations are systematically made, there turn out to be 230 cases, a conclusion reached nearly simultaneously in the 1890s by E. S. Federov (a Russian), A. Schoenflies (a German) and W. Barlow (an Englishman). These cases are known as space groups, because in each case all the operations of the symmetry elements leave three-dimensional space unmoved.

Space groups are related to point groups in a way which can be understood by considering how crystal faces related by screw axes or glide planes would appear to the eye. The translation component of each of these symmetry elements is a fraction of a cell translation, that is, of the order of atomic dimension, and so cannot be detected by eye. Two crystal faces related by a screw axis  $n_m$ , therefore, appear to be related by a pure rotation axis  $n$ . The screw axis  $n_m$  and the rotation axis  $n$  are said to be isogonal because they relate faces separated by the same angle. In more sophisticated language, implying an understanding of the mathematical theory of groups (*q.v.*), they are also said to be isomorphic (or isomorphous, a term which may be confused with isomorphous replacement of one atom by another).

FIG. 15.—REPETITION OF A POINT BY A GLIDE REFLECTION

TABLE XI.—Designations of Glide Planes

Type	Label	Value of translation component
Axial glides	$a$	$\tau$ is parallel to $a$ and is equal to the vector $\frac{1}{2}a$
	$b$	$\tau$ is parallel to $b$ and is equal to the vector $\frac{1}{2}b$
	$c$	$\tau$ is parallel to $c$ and is equal to the vector $\frac{1}{2}c$
Diagonal glide	$n$	$\tau$ is parallel to the face diagonal of a cell, and is equal to the vector $\frac{1}{2}a + \frac{1}{2}b$ or $\frac{1}{2}b + \frac{1}{2}c$ or $\frac{1}{2}c + \frac{1}{2}a$
Diamond glide	$d$	$\tau$ is parallel to the face diagonal of an F cell and is equal to the vector $\frac{1}{4}a + \frac{1}{4}b$ or $\frac{1}{4}b + \frac{1}{4}c$ or $\frac{1}{4}c + \frac{1}{4}a$

If all translations are removed from the symmetry elements of a space group, it degenerates into a point group. In general, many space groups would degenerate into the same point group. Conversely, to every point group there correspond several space groups. The several space groups corresponding to a given point group differ by (1) being based upon alternative permissible lattices of fig. 10; (2) replacement of the rotation axes of the point group with isogonal rotation axes or screw axes; and (3) replacement of the mirrors of the point group with isogonal mirrors or glide planes. If a crystal is found to have external symmetry corresponding to a given point group, it can have an internal symmetry corresponding to any one of the space groups isogonal with that point group.

The various space groups corresponding to a given point group differ from one another by lattice translations or by translation components of screw axes and glide planes. Information on space groups can be obtained by any observation which provides a way of measuring the spacings between equivalent planes in a crystal; *e.g.*, by X-ray and other diffraction methods. Certain observations of morphology, although they are not measurements, also provide information on relative spacings. These observations are discussed later. Such observations lead to the finding of translations characteristic of the space groups isogonal with a given point group.

## VIII. DIFFRACTION BY CRYSTALS

An arrangement of points capable of scattering radiation can be studied with the aid of the scattered radiation. If the distance between scattering centres is of the order of magnitude of the wave length of the radiation, interference effects are observed between the scattered rays, and the resulting phenomenon becomes

diffraction (see LIGHT: Diffraction).

**1. Laue Equations.**—When the scattering centres are regularly arranged, as in a crystal, they constitute a three-dimensional diffraction grating whose diffraction effects are concentrated into very sharp maxima. These maxima are controlled by a set of three equations known as the Laue equations. Each equation gives the condition under which radiation of wave length  $\lambda$ , striking a line of translation-equivalent scattering points at angle  $\mu$ , is in phase as it leaves the line at angle  $\bar{\nu}$ . If the three translations are  $a$ ,  $b$  and  $c$ , as in a crystal, the three Laue equations are

$$\begin{aligned}\cos \bar{\nu}_1 &= \cos \mu_1 + \frac{h'}{a} \lambda \\ \cos \bar{\nu}_2 &= \cos \mu_2 + \frac{k'}{b} \lambda \\ \cos \bar{\nu}_3 &= \cos \mu_3 + \frac{l'}{c} \lambda\end{aligned}\quad (7)$$

where  $h'$ ,  $k'$  and  $l'$  are integers.

In most modern experimental work,  $\lambda$  is held constant; that is, monochromatic X-rays are used. These three equations are then not simultaneously satisfied except when  $\bar{\nu}_1$ ,  $\bar{\nu}_2$  and  $\bar{\nu}_3$  are given special values, which implies that the crystal is given a special orientation with respect to the beam of incoming radiation. In experimental work, the radiation is most commonly X-rays, but it may be a beam of electrons or neutrons (see ELECTRON DIFFRACTION; SPECTROSCOPY, X-RAY; X-RAYS).

**2. Bragg's Law.**—The diffraction maxima can also be interpreted in another manner developed by Sir Lawrence Bragg (illustrated in fig. 16). The periodic nature of the crystal, fig. 16(A),

FIG. 16.—(A) SET OF POINTS IN LATTICE ARRAY; (B) SIMPLE STRUCTURE OF (A) RESOLVED INTO A STACK OF PLANES; (C) REFLECTION FROM A SINGLE PLANE. WAVE FRONT ABC OF X-RAY BEAM IS SCATTERED BY ATOMS Q, R AND S, RESULTING IN WAVE FRONT A'B'C'; (D) REFLECTION BY A STACK OF PLANES. IN ORDER FOR ALL WAVES REFLECTED FROM PLANES 1 AND 2 TO BE IN PHASE ALONG WAVE FRONT DC, THE ADDITIONAL PATH LENGTH FGH OFFERED TO THE X-RAYS BY PLANE 2 MUST EQUAL AN INTEGRAL NUMBER OF WAVE LENGTHS

can be thought of as resolved into planes whose indices are  $(hkl)$ , fig. 16(B). Each plane scatters the radiation as if it were reflecting the rays, fig. 16(C). The condition that the reflected rays from adjacent planes of the stack be in phase, fig. 16(D), is given by Bragg's law,

$$n\lambda = 2d_{hkl} \sin \theta, \quad (8)$$

where  $n$  is an integer giving the number of wave lengths of phase lag between rays scattered by adjacent planes.

Bragg's law can also be written

$$\sin \theta = \frac{\lambda}{2} \frac{1}{d_{hkl}/n} \quad (9)$$

$$= \frac{\lambda}{2} \frac{1}{d_{nh, nk, nl}} \quad (10)$$

It develops that the integers in (7), (8), (9) and (10) are related by

$$\begin{aligned}h' &= nh \\ k' &= nk \\ l' &= nl\end{aligned}\quad (11)$$

The triple of numbers,  $nh \ nk \ nl$ , written without parentheses or brackets are known as the indices of the reflection.

For a selected  $d_{hkl}$  of (9) there are several discrete values of the glancing angle  $\theta$ . If  $n$  is also fixed, there is only one value of  $\theta$ . Conversely, any X-ray method which measures  $\theta$  permits determination of the corresponding spacing  $d$  of the particular set of planes  $hkl$  of the lattice.

FIG. 17.—GEOMETRICAL REPRESENTATION OF BRAGG'S LAW

FIG. 17.—GEOMETRICAL REPRESENTATION OF BRAGG'S LAW

This is illustrated in two dimensions for an orthogonal lattice in fig. 19. If any plane  $(hkl)$  is drawn in the lattice of fig. 19(A), a spacing  $d_{hkl}$  is determined. If a line is drawn in fig. 19(B) from an origin, parallel to  $d_{hkl}$  but equal in length to its reciprocal,  $1/d_{hkl}$ , a point  $P_{hkl}$  is reached. If this is done for all planes  $(hkl)$  of the cell of fig. 19(A) a collection of points is determined as in fig. 19(B). These points can be shown to lie on a lattice. Thus the set of  $1/d$ 's of a lattice determines another lattice. This new lattice is said to be the reciprocal lattice of the crystal. Each point with co-ordinates  $[hkl]$  in the reciprocal lattice corresponds to a plane in the direct lattice whose indices are  $(hkl)$  and to a reflection whose indices are  $hkl$  (without parentheses).

An interesting interpretation of Bragg's law for the entire crystal can be given as shown in fig. 18. If the reciprocal lattice is imagined to be placed so that its origin is at O, then if any point  $P_{hkl}$  of the reciprocal lattice comes to lie on the sphere (called the sphere of reflection) the plane  $(hkl)$  of the crystal reflects, causing a diffraction maximum, or reflection, labeled  $hkl$ .

**4. Diffraction Methods.**—A properly designed X-ray-diffraction experiment is capable of revealing the point symmetry of the crystal, except that all point symmetries appear to have an inversion centre added if an inversion centre is not already present. This is because (unless the wave length  $\lambda$  has a critical value and

FIG. 19.—(A) TWO-DIMENSIONAL EQUIVALENT OF A PLANE WITH INDICES  $hkl$ ; (B) RECIPROCAL LATTICE BUILT UP OF POINTS AT THE ENDS OF VECTORS  $1/d$  OF (A)

gives rise to anomalous dispersion) the reflections from planes  $(hkl)$  and  $(\bar{h}\bar{k}\bar{l})$  have the same intensity, which is the only measurable feature of the diffraction maximum. In general, these reflected waves differ in phase, but the phase cannot be directly measured. These facts are known as Friedel's law. The symmetry displayed by the crystal is usually called Laue symmetry, but would better be called Friedel symmetry.

FIG. 18.—USE OF FIG. 17 IN VISUALIZING REFLECTION BY A PLANE

FROM M. J. BUEGER, "X-RAY CRYSTALLOGRAPHY," REPRODUCED BY PERMISSION OF JOHN WILEY & SONS, INC.

dimensions. But powder photographs are chiefly used in an empirical manner as "finger-prints" of a substance.

**Laue Method.**—Equation (9) shows that if  $\lambda$  is allowed to be variable, a fixed value of  $d$  gives a particular solution for  $\theta$ . Therefore, if a beam of polychromatic X-rays is passed through a single crystal, each reflection occurs at a characteristic angle  $\theta$ , and this information can be recorded on a photographic film, fig. 23. The result is called a Laue photograph. This method gives information on the Friedel symmetry, but no direct unit cell and space-group information. The Laue method was the one used in 1913 by Laue's collaborators W. Friedrich and P. Knipping, when they discovered the diffraction of X-rays by crystals.

FIG. 23.—LAUE PHOTOGRAPH OF QUARTZ,  $\text{SiO}_2$ . THE X-RAY BEAM WAS DIRECTED ALONG THE  $c$  AXIS OF THE CRYSTAL.

## IX. CRYSTAL-STRUCTURE ANALYSIS

Crystal-structure analysis started in 1913 with Max Laue's surmise that, since X-rays probably had wave lengths of the order of magnitude of the distances between atoms in a crystal, they should be diffracted by crystals. The experiments of Friedrich and Knipping proved he was right (see X-RAYS: *Historical Background*).

Crystal-structure analysis has made known the arrangements of atoms in crystals of many thousands of compounds. This information has formed the basis of crystal chemistry. Through crystal chemistry the entire structure of chemistry has been affected, and with it, metallurgy and mineralogy have been placed on a more rational basis. Indeed, all of the present-day science concerned with the structure and properties of solid matter has been placed on a firm foundation through the contributions of crystal-structure analysis.

**1. A Grating and Its Diffraction.**—It was explained in the preceding section that the symmetry of a crystal and the dimensions of its cell can be found by relatively simple diffraction experiments. The cell dimensions are determined by the position of the diffraction maxima and the Friedel symmetry is determined by the symmetry of the distribution of the maxima. In addition to this, the relative intensities of the reflections  $hkl$  are governed by the distribution of matter (that is, by the arrangement of atoms) in the cell.

More generally, the distribution of scattering matter in a grating and the diffraction it produces are related. If everything is known about either of these, the other is completely determined, and can be computed through a mathematical device known as the Fourier transform. Let

- $hkl$  = the indices of a reflection
- $f_{j,hkl}$  = the scattering power of atom  $j$  for reflection  $hkl$
- $F_{hkl}$  = the amplitude of the radiation scattered in reflection  $hkl$
- $xyz$  = the co-ordinates of a point in the unit cell
- $\rho_{xyz}$  = the electron density at co-ordinates  $xyz$
- $V$  = the volume of the unit cell

Then the relation between the distribution of matter in a crystal and the diffraction it produces is given by the two Fourier transforms

$$F_{hkl} = \sum_i f_{i,hkl} e^{i2\pi(hx+ky+lz)} \quad (13)$$

$$\rho_{xyz} = \frac{1}{V} \sum_h \sum_k \sum_l F_{hkl} e^{-i2\pi(hx+ky+lz)} \quad (14)$$

The scattering powers,  $f_{j,hkl}$ , of the various atoms are known, so that the amplitude diffracted by any crystal in reflection  $hkl$  can be computed by (13). In general this amplitude  $F_{hkl}$  is complex; that is, it has both magnitude  $|F_{hkl}|$ , and phase  $\phi_{hkl}$ . When the crystal has a centre of symmetry and this is chosen as origin,

the exponentials of both (13) and (14) degenerate into cosines, and the complex character of  $F_{hkl}$  degenerates into a positive or negative number; that is, the phase of  $F_{hkl}$  assumes the nature of a sign, + or -. Thus the diffraction can be easily computed for a known pattern of atoms.

Problems arise when an attempt is made to derive the arrangement of matter in a crystal by (14) from the measured diffraction. Since  $F_{hkl}$  is, in general, complex, it can be written

$$F_{hkl} = |F_{hkl}| e^{i\phi_{hkl}} \quad (15)$$

which implies that it has both magnitude and phase. Only the magnitude can be measured, so that (14) cannot be solved as a simple routine based on measured quantities. This constitutes what is called the *phase problem* of crystal-structure analysis. Ways used to circumvent the phase problem will be noted later.

**2. The Data of Crystal-Structure Analysis.**—To find the arrangement of atoms in a crystal the intensities of the various reflections  $hkl$  must first be measured. This can be done by measuring or estimating the blackness of the spots corresponding to each reflection as they appear on the photographs made by one of the methods outlined earlier. For this purpose the precession and Weissenberg methods are preferred, since they resolve all reflections. The oscillating-crystal, rotating-crystal and power photographs are sometimes employed, but their use involves difficulties because, in that order, they give increasingly less resolution of reflections and increasingly less symmetry information. The Laue method is not currently used because the reflections come from a spectrum of wave lengths of varying but unknown intensities.

More quantitative measures of the diffraction intensities can be made by using a single-crystal diffractometer. Such instruments are designed to allow the crystal to be set in the orientation to produce any desired reflection,  $hkl$ , and to allow a quantum counter (e.g., a Geiger counter) to be placed in such a position as to receive the reflection. The number of quanta registered by the counter is then recorded as the crystal is uniformly rotated through the desired reflection. This provides a measure known as the integrated reflection.

The integrated reflection must be corrected for several factors known as the Lorentz, polarization and absorption factors, and possibly for primary- and secondary-extinction effects. The first two are routine geometrical corrections, but the remainder cause technical difficulties. When the corrections have been made, the resulting numbers are proportional to  $|F_{hkl}|^2$ , that is, to the squares of the magnitudes of the amplitudes, from which the  $|F_{hkl}|$ 's of (15) can be easily derived.

**3. Circumventing the Phase Problem.**—With a full set of  $|F_{hkl}|$ 's available, (14) still cannot be solved because  $e^{i\phi_{hkl}}$  of (15) is unknown. There are a number of ways of finding this factor or its equivalent, but many of the methods apply only to relatively simple structures in which there are a comparatively small number of atoms per unit cell.

**Trial Models.**—For crystals of some substances, the small size of the cell together with a knowledge of crystal chemistry (or in organic substances, the known structure and shape of the molecule) may permit the general packing of molecules or groups of atoms in the cell to be guessed. In such instances the guess constitutes a rough model for which the expected diffraction can be computed by (13). These calculated  $\phi$ 's may then be combined with the observed  $|F_{hkl}|$ 's with the aid of (15) to give a set of hybrid  $F_{hkl}$ 's which can then be used to compute (14). If the guessed model was essentially correct, its more exact distribution of electron density is then provided by this use of (14). This distribution of the electron density should essentially duplicate the arrangement of atoms in the trial model, and should also meet certain technical criteria. If it does not, the trial model is discarded for another. But if it does, the positions of the atoms are found to have been improved over those of the trial model. From this first improved model, new phases  $\phi$  of (15) can be computed, using (13), and then (14) can be computed again. In this way the method of successive Fourier syntheses ultimately gives the correct location of atoms.

**Heavy-Atom Method.**—The various  $f$ 's in the summation of

(13) are the scattering powers of the several atoms in the unit cell, and these, in turn, are roughly proportional to the atomic numbers,  $Z$ , of these atoms. If the cell contains one heavy atom, or a symmetry-equivalent set of them, these contribute the largest  $f$ 's to the summation and tend to dominate the sum. The few heavy atoms can often be located, because they must occur in such small numbers that they can only be on symmetry-fixed locations of the space group. Alternatively they can be located by the Patterson synthesis, discussed later. Since the heavy atoms dominate (13), their contribution alone can be used to compute approximate values for (13). This determines rough values of  $\phi$  in (15), and these permit (14) to be computed. This preliminary computation of the electron density not only reveals the heavy atoms, but other lighter atoms as well. From this point forward, the structure is refined by the method of successive Fourier syntheses.

Many complicated crystal structures have been solved by this method. Most such crystals are those of organic compounds in which a heavy atom has been deliberately attached to the organic molecule.

**Replaceable-Atom Method.**—Phases can be computed directly for the scattering of the entire cell provided that two crystals are available which have the same structure except for one (or a few) symmetry-equivalent set of atoms, which can be located. For example, the compounds  $\text{Mg}_2(\text{OH})_3\text{Cl} \cdot 4\text{H}_2\text{O}$  and  $\text{Mg}_2(\text{OH})_3\text{Br} \cdot 4\text{H}_2\text{O}$  have the same structure but differ by replacement of Cl by Br. That they have the same structure is judged by the fact that the crystals have similar cells, symmetry and other properties. In such cases, when the location of the replaceable atom is found (as in the heavy-atom case), the magnitudes and phases scattered by this atom can be determined, and this information can be combined with the measured magnitudes to provide the missing phases in (15). Thus (14) can be computed and the electron density found.

**Direct Fourier Methods.**—The methods noted so far are useful only in certain special cases. Fortunately there have been discovered a number of direct methods which are based upon the realization that, in a set of diffraction amplitudes scattered by matter concentrated in discrete atoms, the set of phases is not independent of the set of magnitudes. Now, it has been noted that for crystals containing inversion centres, the phases of the  $F$ 's can be expressed as signs of these  $F$ 's in (14). In making use of the relations of magnitudes and signs, it is convenient to normalize each  $F_{hkl}$  in such a way that it would be unity if all atoms scattered in phase for this reflection. Such normalized  $F$ 's are called unitary structure factors and are labeled  $U$ 's.

Using this kind of diffraction amplitude, David Harker and J. S. Kasper were able to demonstrate that the signs of the  $U$ 's are subject to the following restriction:

$$|U_{hkl}|^2 < \frac{1}{2} + \frac{1}{2} U_{2h, 2k, 2l} \quad (16)$$

The left side does not involve a phase, and therefore it can be measured. If it is greater than  $1/2$ , (16) can only be satisfied if  $U_{2h, 2k, 2l}$  is positive. (No conclusion can be drawn if the left side is less than  $1/2$ .) There are many relations like (16) that are based upon the presence of various symmetry elements in the crystal.

Another, more useful, relation, due to D. Sayre, W. H. Zachariasen and others, is:

$$S_h + S'_h + S'_l + S'_l = S(S_{hkl} S'_h S'_l) \quad (17)$$

This says that if the signs ("S") of the two reflections,  $hkl$  and  $h'k'l'$  are known, the sign of the product of their signs is the same as the sign of the reflection  $h + h', k + k', l + l'$ . This relation holds well when  $hkl$  and  $h'k'l'$  are strong reflections. It has also been shown to hold if the product is averaged over signs for sets of reflections such that  $h + h', k + k'$  and  $l + l'$  is constant. These relations are useful in establishing the signs of some reflections if the signs of some others have been found. In addition there are other more complicated statistical relations known.

**Vector-Space Methods.**—Since the phases of the complex  $F$ 's are

not directly available for a complete determination of the electron density by (14), the question arises as to just what is determined by the bare magnitudes,  $|F_{hkl}|$ , of the diffraction amplitudes. This question was answered by A. L. Patterson, who deduced a new summation known as the Patterson function or Patterson synthesis:

$$P_{uvw} = \sum_h \sum_k \sum_l |F_{hkl}|^2 \cos 2\pi(hu + kv + lw). \quad (18)$$

In this summation the squares of the magnitudes of the diffraction amplitudes alone enter, and these are entirely observable. This synthesis has the property that it has maxima at the ends of vectors radiating from the origin which correspond to interatomic vectors in the crystal. Thus the diffraction magnitudes enable the vectors between atoms in the structure to be determined, but do not directly provide the locations of the atoms of that structure. The relation is similar to have the individual pieces of a structure like a bridge, but not having a plan of how they are attached to one another.

The Patterson peak locations have been tabulated for one set of symmetry-equivalent atoms for every space group. Furthermore, the Patterson function exaggerates the peak locations representing vectors between heavy atoms. These two circumstances make it possible to use the Patterson function to locate the heavy atoms for the heavy-atom method, and in this way the Patterson function has contributed to the solution of many crystal structures.

The space in which the Patterson synthesis may be said to occur (or be plotted) is called vector space. A detailed study of the relations between crystal space and vector space has resulted in the development of a number of ways of transforming the Patterson synthesis into a map of the approximate electron density. The basis of this is called image theory. The Patterson synthesis can be regarded as the image of the crystal structure as seen from one atom, but summed over all atoms of the structure. Solution of the Patterson synthesis consists of isolating one image from the others. This is done by the use of mathematical devices known as image-seeking functions. Many crystal structures of moderate complexity have been solved by these methods.

**4. Refinement of Structures.**—The chief barrier in crystal-structure analysis is that concerned with the determination of the approximate location of the atoms. Once this barrier has been surmounted, a number of methods are available for increasing the accuracy of the atom locations. The method of successive Fourier synthesis has already been mentioned. In another method, the electron density is, in effect, computed twice, once using observed magnitudes and the second time using magnitudes predicted by the first model. The difference between the two (called a difference synthesis) should be featureless if the model is the same as the actual structure. If not, the synthesis displays anomalies which indicate which way the atoms should be shifted in order to cause the model to become the same as the true structure. A third method utilizes the method of least squares, and reveals what shifts of atom co-ordinates are required to give a better fit of computed intensities with observed intensities. This method also permits estimation of the thermal motions of the atoms. There are several other refinement methods in use.

The course of a refinement is usually followed by an estimate of the average error by which the diffraction amplitudes computed from the model fail to duplicate those actually measured. There are a number of particular measures of this sort in use; a common one is the average residual

$$R = \frac{\sum (|F_{\text{observed}}| - |F_{\text{computed}}|)}{\sum |F_{\text{observed}}|} \quad (19)$$

(M. J. Bu.)

## X. OPTICAL CRYSTALLOGRAPHY

The optical properties of crystals are not only of considerable interest theoretically, but are of the greatest practical importance. Crystals of calcite (Iceland spar) are employed in producing polarized light. The science of petrology is largely based on the study of the appearance of thin sections of rocks in a microscope

fitted with two polarizing calcite prisms (*see* MICROSCOPE: *Illumination: Polarized Light*). In the absence of external crystal-line form, as with a faceted gem stone, or with the minerals constituting a rock (thin, transparent sections of which can be examined in the polarizing microscope), a mineral may often be readily identified by the determination of some of its optical properties.

According to their action on transmitted plane-polarized light (*see* LIGHT: *Polarization and Electromagnetic Theory*), all crystals may be referred to one or another of the five groups enumerated below. These groups correspond with the six systems of crystallization (in the second group two systems are included together). The several symmetry classes of each system are optically the same, except in the rare cases of substances which are circularly polarizing.

1. Optically isotropic crystals—corresponding with the cubic system.

2. Optically uniaxial crystals—corresponding with the tetragonal and hexagonal systems.

3. Optically biaxial crystals in which the three principal optical directions coincide with the three crystallographic axes—corresponding with the orthorhombic system.

4. Optically biaxial crystals in which only one of the three principal optical directions coincides with a crystallographic axis—corresponding with the monoclinic system.

5. Optically biaxial crystals in which there is no fixed and definite relation between the optical and crystallographic directions—corresponding with the triclinic system.

**1. Optically Isotropic Crystals.**—These belong to the cubic system and, like all other optically isotropic bodies, have only one index of refraction for light of each colour. They have no action on polarized light (except in crystals which are circularly polarizing); and when examined in the polariscope or polarizing microscope they remain dark between crossed Nicols or Polaroids, and cannot be distinguished optically from amorphous substances such as glass.

**2. Optically Uniaxial Crystals.**—These belong to the tetragonal and hexagonal (including rhombohedral) systems, and between crystals of these systems there is no optical distinction. Such crystals are anisotropic or doubly refracting (*see* LIGHT: *Refraction and Double Refraction*), but for light traveling through them in a certain, single direction they are singly refracting. This direction, which is called the optic axis, is the same for light of all colours and at all temperatures; it coincides in direction with the principal crystallographic axis, which in tetragonal crystals is a 4-fold (or  $\bar{4}$ ) axis of symmetry, and in the hexagonal system a 3-fold or 6-fold axis.

For light of each colour there are two indices of refraction; namely, the ordinary index ( $\omega$ ) corresponding with the ordinary ray, which vibrates perpendicular to the optic axis; and the extraordinary index ( $\epsilon$ ) corresponding with the extraordinary ray, which vibrates parallel to the optic axis. If the ordinary index of refraction is greater than the extraordinary index, the crystal is said to be optically negative, while if less the crystal is optically positive. The difference between the two indices is a measure of the strength of the double refraction or birefringence. Thus in calcite, for sodium (D) light,  $\omega = 1.6585$  and  $\epsilon = 1.4863$ ; hence this substance is optically negative with a relatively high double refraction of  $\omega - \epsilon = 0.1722$ . For sodium light in quartz,  $\omega = 1.5442$ ,  $\epsilon = 1.5533$  and  $\epsilon - \omega = 0.0091$ ; this mineral is therefore optically positive with low double refraction. The indices of refraction vary not only for light of different colours but also slightly with the temperature.

The optical characteristics of uniaxial crystals are symmetrical not only with respect to the full number of planes and axes of symmetry of tetragonal and hexagonal crystals, but also with respect to all vertical planes; *i.e.*, all planes containing the optic axis. A surface expressing the optical relations of such crystals is thus an ellipsoid of revolution about the optic axis. (In cubic crystals the corresponding surface is a sphere.) The optical indicatrix, or index ellipsoid, is the surface obtained by plotting the value of the refractive index in each principal direction for a

linearly polarized light vector lying in that direction. In the optical indicatrix the length of the principal axis, or axis of rotation, is proportional to the index of refraction (*i.e.*, inversely proportional to the velocity) of the extraordinary rays, which vibrate along this axis and are transmitted in directions perpendicular thereto; the equatorial diameters are proportional to the index of refraction of the ordinary rays, which vibrate perpendicular to the optic axis. For positive uniaxial crystals the indicatrix is thus a prolate spheroid (lemon-shaped), and for negative crystals an oblate spheroid (doorknob-shaped).

In uniaxial crystals the ray surface, or wave surface, which represents the distances traversed by the rays during a given interval of time in various directions from a point of origin within the crystal, consists of two sheets; namely, a sphere, corresponding to the ordinary rays, and an ellipsoid of revolution, corresponding to the extraordinary rays. The difference in form of the ray surface for positive and negative crystals is shown in fig. 24.

FIG 24 —RAY-SURFACE SECTION OF (A) POSITIVE UNIAXIAL CRYSTAL AND (B) NEGATIVE UNIAXIAL CRYSTAL

When a uniaxial crystal is examined in a polariscope or polarizing microscope between crossed Nicols (*i.e.*, with the principal planes of the polarizer or analyzer at right angles, and so producing a dark field of view), its optical behaviour differs according to the direction in which the light travels through the crystal, to the position of the crystal with respect to the principal planes of the Nicols, and according to whether convergent or parallel polarized light is employed. A tetragonal or hexagonal crystal viewed in parallel light, along the principal axis will remain dark as it is rotated between crossed Nicols, and will thus not differ in its behaviour from a cubic crystal or other isotropic body. If, however, the crystal is viewed in any other direction (for example, through a prism face), it will, except in certain positions, have an action on the polarized light. A plane-polarized ray entering the crystal will be resolved into two polarized rays having their directions of vibration parallel to the vibration directions in the crystal. These two rays on leaving the crystal will be combined again in the analyzer, and a portion of the light will be transmitted through the instrument; the crystal will then show up brightly against the dark field. Furthermore, because of interference of these two rays in the analyzer, the light will be brilliantly coloured, especially if the crystal is thin, or if a thin section of a crystal is examined. The particular colour seen will depend on the strength of the double refraction, on the orientation of the crystal or section, and on its thickness. If, now, the crystal is rotated with the stage of the microscope, the Nicols remaining fixed in position, the light transmitted through the instrument will vary in intensity and in certain positions will be cut out altogether. The latter happens when the vibration directions of the crystal are parallel to the vibration directions of the Nicols (these being indicated by cross hairs in the microscope). The crystal, now being dark, is said to be in position of extinction, and as it is turned through a complete rotation of  $360^\circ$  it will extinguish four times. If the crystal is viewed through a prism face, it will be seen that, when the crystal is in a position of extinction, the cross hairs of the microscope are parallel to the edges of the prism; the crystal is then said to give straight extinction or parallel extinction.

In convergent light, a very different phenomenon is observed when a uniaxial crystal, or section of such a crystal, is placed between crossed Nicols with its optic axis coincident with the axis of the microscope. The rays of light, being convergent, do not travel in the direction of the optic axis and are therefore doubly refracted in the crystal; in the analyzer the vibrations will

be reduced to the same plane and there will be interference of the two sets of rays. The result is an interference figure (fig. 25) consisting of a number of brilliantly coloured concentric rings, each showing the colours of the spectrum of white light; intersecting the rings is a black cross, the arms of which are parallel to the principal planes of the Nicols. If monochromatic light is used instead of white light, the rings will be alternately light and dark. The number and distance apart of the rings depend on the strength of the double refraction and on the thickness of the crystal. By observing the effect produced on such a uniaxial interference figure when a quartz wedge, a gypsum plate or a mica plate is superposed on the crystal, it may be at once decided whether the crystal is optically positive or negative. Such a simple test may, for example, be applied for distinguishing certain faceted gem stones: thus zircon and phenacite are optically positive, while corundum (ruby and sapphire) and beryl (emerald) are optically negative.

**3. Optically Biaxial Crystals.**—In these crystals there are three principal indices of refraction, denoted by  $\alpha$ ,  $\beta$  and  $\gamma$ ; of these,  $\gamma$  is the greatest and  $\alpha$  the least ( $\alpha < \beta < \gamma$ ). The three principal vibration directions corresponding to these indices are at right angles to each other, and are the directions of the three rectangular axes of the optical indicatrix. The indicatrix (fig. 26) is an ellipsoid with the lengths of its axes proportional to the refractive indices;  $OC:\gamma$ ,  $OB:\beta$ ,  $OA:\alpha$ , where  $OC > OB > OA$ . The figure is symmetrical with respect to the principal planes  $OAB$ ,  $OAC$ ,  $OBC$ .

The ray surface (represented in fig. 27 by its sections in the three principal planes) is derived from the indicatrix in the following manner. A ray of light entering the crystal and traveling in the direction  $OA$  is resolved into polarized rays vibrating parallel to  $OB$  and  $OC$ , and therefore propagated with the velocities  $1/\beta$  and  $1/\gamma$  respectively (with the velocity of light in vacuum taken to be unity): distances  $Ob$  and  $Oc$  (fig. 27) proportional to these velocities are marked off in the direction  $OA$ . Similarly, rays traveling along the  $OC$  have the velocities  $1/\alpha$  and  $1/\beta$ , and those along  $OB$  the velocities  $1/\alpha$  and  $1/\gamma$ . In the two directions  $Op_1$  and  $Op_2$  (fig. 26) perpendicular to the two circular sections  $P_1P_1$  and  $P_2P_2$  of the indicatrix, the two rays will be transmitted with the same velocity  $1/\beta$ . These two directions are called the optic axes (primary optic axes), although they do not have all the properties associated with the optic axis of a uniaxial crystal. They have very nearly the same direction as the lines  $Os_1$  and  $Os_2$  in fig. 27, which are distinguished as the secondary optic axes. In most crystals the primary and secondary optic axes are inclined to each other at not more than a few minutes, so that for practical purposes there is no distinction between them.

The angle between  $Op_1$  and  $Op_2$  is called the optic axial angle, and the plane  $OAC$  in which these lines lie is called the optic axial plane. The angles between the optic axes are bisected by the vibration directions  $OA$  and  $OC$ , the line which bisects the acute angle being called the acute bisectrix and the other the obtuse bisectrix. When the acute bisectrix coincides with the greatest axis  $OC$  of the indicatrix, i.e., the vibration direction corresponding with the refractive index  $\gamma$  (as in fig. 26 and 27), the crystal is described as being optically positive; and when the acute bisectrix coincides with  $OA$ , the vibration direction for the index  $\alpha$ , the crystal is negative.

FIG. 25.—INTERFERENCE FIGURE OF A UNIAXIAL CRYSTAL

FIG. 26.—OPTICAL INDICATRIX OF A BIAXIAL CRYSTAL

The distinction between positive and negative biaxial crystals thus depends on the relative magnitude of the three principal indices of refraction; in positive crystals  $\beta$  is nearer to  $\alpha$  than to  $\gamma$  while in negative crystals the reverse is the case. Thus in topaz, which is optically positive, the refractive indices for sodium light are  $\alpha = 1.6120$ ,  $\beta = 1.6150$ ,  $\gamma = 1.6224$ ; and for orthoclase, which is optically negative,  $\alpha = 1.5190$ ,  $\beta = 1.5237$ ,  $\gamma = 1.5260$ . The difference  $\gamma - \alpha$  represents the strength of the double refraction.

Since the refractive indices vary both with the colour of the light and with the temperature, there will be for each colour and temperature slight differences in the form of both the indicatrix and the ray surface; consequently there will be variations in the positions of the optic axes and in the size of the optic axial angle. This phenomenon is known as the dispersion of the optic axes. When the axial angle is greater for red light than for blue the character of the dispersion is expressed by  $r > v$  and when less by  $r < v$ . In some crystals, e.g., brookite, the optic axes for red light and for blue light may be, at certain temperatures, in planes at right angles. The type of interference figure exhibited by a bi-

FIG. 28.—INTERFERENCE FIGURES OF A BIAXIAL CRYSTAL

axial crystal in convergent polarized light between crossed Nicol prisms is represented in fig. 28. The crystal must be viewed along the acute bisectrix, and for this purpose it is often necessary to cut a plate from the crystal perpendicular to this direction; sometimes, however, as in mica and topaz, a cleavage flake will be perpendicular to the acute bisectrix. When the crystal is viewed in white light, there are around each optic axis a series of brilliantly coloured ovals, which at the centre join to form an 8-shaped loop, while farther from the centre the curvature of the rings is approximately that of lemniscates. In the position shown in fig. 28(A) the vibration directions in the crystal are parallel to those of the Nicols, and the figure is intersected by two black bands or brushes forming a cross. When the crystal is rotated with the stage of the microscope, the cross breaks up into the two branches of a hyperbola, and when the vibration directions of the crystal are inclined at  $45^\circ$  to those of the Nicols the interference figure is as shown in fig. 28(B). Points of emergence of the optic axes are at the middle of the hyperbolic brushes when the crystal is in the diagonal position, and the size of the optic axial angle can therefore be directly measured with considerable accuracy.

In orthorhombic crystals the three principal vibration directions coincide with the three crystallographic axes, and therefore have fixed positions in the crystal which are the same for light of all colours and at all temperatures. The optical orientation of an orthorhombic crystal is completely defined by stating to which crystallographic planes the optic axial plane and the acute bisectrix are respectively parallel and perpendicular. When examined in parallel light between crossed Nicols, such a crystal extinguishes parallel to the crystallographic axes, which are often parallel to the edges of a face or section; there is thus usually straight extinction. The interference figure seen in convergent polarized light is symmetrical about two lines at right angles.

In monoclinic crystals only one vibration direction has a fixed position within the crystal; it is parallel to the 2 or  $\bar{2}$  axis. The other two vibration directions lie in a plane perpendicular to this axis, but they may vary in position for light of different colours and at different temperatures. Thus, in crystals of this system, in addition to dispersion of the optic axes there may also be dispersion of the bisectrices. The latter may be of one or another of three kinds, depending on which of the three vibration directions coincides with the 2 or  $\bar{2}$  axis of the crystal. When the acute bisectrix is fixed in position, the optic axial planes for different colours may be crossed, and the interference figure will then be symmetrical with respect to a point only (crossed dispersion). When the obtuse bisectrix is fixed, the axial planes may be inclined to one another, and the interference figure is symmetrical only about a line which is perpendicular to the axial planes (horizontal

FIG. 27.—RAY SURFACE OF A BIAXIAL CRYSTAL

dispersion). Finally, when the vibration direction corresponding to the refractive index  $\beta$  has a fixed position, the optic axial plane lies perpendicular to the  $2$  or  $\bar{2}$  axis, but the acute bisectrix may vary in position in this plane; the interference figure will then be symmetrical only about a line joining the optic axes (inclined dispersion). Examples of substances exhibiting these three kinds of dispersion are borax, orthoclase and gypsum, respectively. In orthoclase and gypsum, however, the optic axial angle gradually diminishes as the crystals are heated, and after passing through a uniaxial position the angle opens out in a plane at right angles to the one it previously occupied; the character of the dispersion thus becomes reversed in the two examples quoted. When examined in parallel light between crossed Nicols, monoclinic crystals will give straight extinction only in faces and sections which are parallel to the  $2$  or  $\bar{2}$  axis; in all other faces and sections the extinction directions will be inclined to the edges of the crystal. The angles between these directions and edges are readily measured and, being dependent on the optical orientation of the crystal, they are often characteristic constants of the substance.

In triclinic crystals there is no relation between the optical and crystallographic directions, and the exact determination of the optical orientation is often a matter of very considerable difficulty. The character of the dispersion of the bisectrices and optic axes is more complex than in monoclinic crystals, and the interference figures are devoid of symmetry.

**4. Absorption of Light in Crystals; Pleochroism.**—In crystals other than those of the cubic system, rays of light with different vibration directions will, as a rule, be differently absorbed, and the polarized rays on emerging from the crystal may be of different intensities and (if the observation is made in white light and the crystal is coloured) differently coloured. Thus in tourmaline the ordinary ray, which vibrates perpendicular to the principal axis, is almost completely absorbed, while the extraordinary ray is allowed to pass through the crystal. A plate of tourmaline cut parallel to the principal axis may therefore be used for producing a beam of polarized light, and two such plates placed in crossed position form the polarizer or analyzer of tourmaline tongs, with the aid of which the interference figures of crystals may be simply shown.

Uniaxial (tetragonal and hexagonal) crystals that show perceptible differences in colour for the ordinary and extraordinary rays are said to be dichroic. In biaxial (orthorhombic, monoclinic and triclinic) crystals, rays vibrating along each of the three principal vibration directions may be differently absorbed and, in coloured crystals, differently coloured; such crystals are therefore said to be trichroic or in general pleochroic (from *pleon*, more, and *chros*, colour).

The directions of maximum absorption in biaxial crystals have, however, no necessary relation with the axes of the indicatrix, unless these have fixed crystallographic directions, as is the case with the orthorhombic system and with the  $2$  or  $\bar{2}$  axis in the monoclinic system. In epidote it has been shown that the two directions of maximum absorption which lie in the plane of symmetry are not even at right angles. The characteristic absorption bands in the spectrum of white light which has been transmitted through certain crystals, particularly those of salts of the cerium metals, will, of course, be different according to the direction of vibration of the rays.

The pleochroism of some crystals is so strong that when they are viewed through in different directions they exhibit marked differences in colour. Thus a crystal of the mineral cordierite (also called dichroite because of its strong pleochroism) will be seen to be dark blue, pale blue or pale yellow according to which of three perpendicular directions is viewed. The face colours seen directly in this way result, however, from the mixture of two axial colours belonging to rays vibrating in two directions. In order to see the axial colours separately the crystal must be examined with a dichroscope, or in a polarizing microscope from which the analyzer has been removed. The dichroscope consists of a cleavage rhombohedron of calcite, on the ends of which glass prisms are cemented; the lens is focused on a small square aperture in the tube of the instrument. The eye of the observer will

see two images of the square aperture, and if a pleochroic crystal is placed in front of this aperture the two images will be differently coloured. On rotating this crystal with respect to the instrument the maximum difference in the colours will be obtained when the vibration directions in the crystal coincide with those in the calcite. Such a simple instrument is especially useful for the examination of faceted gem stones even when they are mounted in their settings. A single glance suffices to distinguish between a ruby and a spinel ruby, since the former is dichroic and the latter isotropic and therefore not dichroic.

**CRYSTALS, DISLOCATION OF.** Few things in nature are more perfect than a crystal, in which immense numbers of atoms or molecules are stacked in perfect alignment. Rarely is even one atom in a thousand out of line. Yet, surprisingly, many of the most important properties of a crystal are due to the few odd places where the crystal structure goes wrong. Many crystals could not have grown at all without having imperfections in them. Gemstones mostly owe their colours to imperfections. Luminescence, and the special electrical properties of semi-conducting materials such as germanium, are due to them. Imperfections enable atoms to move about and chemical reactions to take place inside crystals. Imperfections at the surfaces of crystals are prone to chemical attack, which is turned to advantage in chemical catalysts but is a source of trouble in corrosion-resistant metals and alloys. Most important of all, engineering metals, which are conglomerates of crystals, owe their great strength, toughness and malleability to the special properties of a certain type of crystal imperfection called a dislocation.

**Types of Dislocations.**—A crystal is an assembly of identical "bricks"—the atoms or molecules—built into a certain architectural pattern or lattice, and a dislocation is an imperfection in that pattern. The simplest patterns, from which perfect crystals are built, are formed by the intersections of three families of equidistant planes; such patterns are also used in the simplest rectilinear architecture. But more complicated patterns are possible which enable one to build curved architectural structures, such as arches, from the same bricks. This is done by matching  $n+1$  bricks in one layer against  $n$  in the next layer, where the

number  $n$  depends on the curvature required, as shown in fig. 1. In the architecture of a crystal this particular pattern is called an edge dislocation. Plastically bent crystals such as are obtained when a soft metal wire is sharply bent, contain edge dislocations and these are the sources of their curvature.

Another type of dislocation, the screw dislocation, has a different architectural property. It enables a three-dimensional structure to be made out of a single flat sheet of material. This sheet is wound about a central axis—the dislocation—like a spiral staircase so that each successive layer of the sheet rests on the one below, as in fig. 2. In crystallography this is equivalent to replacing one of the families of planes in the lattice by a single spiral surface, or helioid.

**Crystal Growth and Growth Steps.**—This property of a screw dislocation is important for the growth of crystals. When a crystal is exposed to a supersaturated vapour or solution of its own substance, atoms or molecules condense on to its surface and move about on it until they meet one another and begin to form new layers of the crystal on top of the existing ones. A difficulty occurs when the vapour or solution is only slightly supersaturated.

The rate of arrival of atoms or molecules on the surface is then so low that one that has arrived is most likely to evaporate off the surface again before it manages to meet others and so begin forming a new layer. Only when a partly grown layer already exists on the surface is such an atom likely to become a permanent part of the crystal, by attaching itself to the "growth step" at the edge of that layer. If the crystal is architecturally perfect, however, a smooth crystal face is produced as this layer grows to the edges of the crystal. It then becomes almost impossible for the crystal to grow further unless the supersaturation is increased to the level at which new layers can form on existing smooth ones. This conclusion is based on sound thermodynamic arguments but is in striking disagreement with the observed fact that most crystals grow easily under the smallest supersaturations. It was pointed out by F. C. Frank in 1949 that such crystals probably contain screw dislocations and grow in the manner suggested by the arrow in fig. 2, by adding more turns to the spiral through the attachment of atoms or molecules to the ledge between the top "stair" and the layer beneath it. The problem of creating

FIG. 2.—BUILDING OF A CRYSTAL BY THE ADDITION OF LATTICE BLOCKS TO THE ENDS OF A SINGLE SPIRAL SHEET AROUND A SCREW DISLOCATION

new growth steps then disappears because the screw dislocation provides a self-perpetuating growth step on the surface. The addition of atoms or molecules to this step does not produce a smooth crystal face but causes the step instead to wind up into a growth spiral on the surface, as in fig. 3. Many crystals have now been observed to grow by this process and the demonstrated existence of such growth spirals has strongly confirmed this aspect of the theory of dislocations. Again there is an architectural

FIG. 1.—(A) EDGE DISLOCATION IN A CURVED BRICK ARCH; (B) EDGE DISLOCATION IN ATOMIC STRUCTURE OF A SIMPLE CURVED CRYSTAL (CIRCLES REPRESENT ATOMS) (SEE TEXT)

analogy in the ziggurats, the spiral pyramids of Mesopotamia.

**"Whisker Crystals."**—In the presence of a solvent or corroding agent the process of fig. 3 can operate in reverse, the point of emergence of the dislocation on the crystal surface being a centre for the dissolution of the crystal. Instead of a growth hill, a depression or etch pit is formed on the crystal face. Etch pits are troublesome in corrosion-resistant materials but useful as a means of locating dislocations in crystals. Atoms or molecules of foreign substances are important in both the growth and dissolution of crystals. By attaching themselves to the growth steps they can block the flow of matter to and from the steps and so obstruct or "poison" the processes. The more slowly a growth step moves across a crystal face the more time there is for other impurities to condense on to that face and slow down the growth still more. This leads to "bunching," in which large numbers of growth steps pile up closely behind a heavily contaminated one and produce steep-sided growth hills and etch pits. In extreme cases it provides one mechanism for the growth of remarkable "whisker crystals"; i.e., crystalline fibres which are typically about 1 cm. long but only about 0.0001–0.001 cm. thick. Fig. 4 shows

FIG. 4.—GROWTH OF CRYSTAL IN WHISKER FORM DUE TO "POISONING" OF THE GROWTH STEP AT ITS BASE BY ADSORBED IMPURITY ATOMS

how the poisoning of a growth step can lead to the formation of a whisker. Practically all crystalline substances have now been observed to grow as whiskers under favourable conditions and the process just described is only one of several by which they are formed. Some materials, e.g., cellulose and asbestos, grow as fibres because their molecules are shaped in that form. In others, particularly the metals, the whiskers often grow from their bases, not their tips, by processes occurring inside the bulk material.

**Slip.**—The idea of dislocations in crystals was introduced in 1934 by G. I. Taylor, E. Orowan and M. Polanyi to explain the plastic deformation of crystals. Experiments made between 1920 and 1930 had already shown that when a crystal is stretched or bent plastically its crystal structure is not destroyed, and that the deformation occurs by the process of slip, as in fig. 5, in which one slab of the crystal slides past another along a surface within the crystal that is commonly one of the main crystallographic planes, called a slip plane, and along a direction in that surface that is always one of the main crystallographic axes, called a slip direction. The coherence and continuity of the crystal across the surface is not destroyed by slip and the atoms come to rest in perfect alignment after having slipped. In some cases the deformation occurs uniformly on a thick packet of such planes and rotates the crystal axes of the material within the packet into a position of mirror symmetry relative to the original axes; it is then called deformation twinning.

FIG. 5.—DEFORMATION PRODUCED BY THE PROCESS OF SLIP IN A STRETCHED CRYSTAL

It is scarcely possible for all the millions of atoms on a slip plane to ride up simultaneously over their neighbours on the opposite face of the plane. The smallest variation in the distribution of applied force on the plane and the natural vibrations of the crystal lattice itself must cause one part to slip before the rest. The slip can then spread outward from this part over the rest of the plane, like a wave spreading over the surface of a pond. The front of this wave, i.e., the boundary line between the slipped and unslipped areas, is the dislocation line. Where this line is parallel to the slip direction the dislocation is a screw and where it is perpendicular the dislocation is an edge. Where it is curved the dislocation is partly a screw and partly an edge. In fig. 3 the line of the screw dislocation is shown as a broken line running

FIG. 3.—GROWTH SPIRAL CENTRED ON A SCREW DISLOCATION

vertically down the centre of the crystal. Fig. 1 (B) may be regarded as a section through the line of the edge dislocation.

Slip dislocations are thus able to move or glide across their slip planes and, in doing this, to cause the material above the slip plane to slide over that below it. This important property of dislocations is illustrated in fig. 6. At each stage during slip the atoms behind the dislocation have completed their movement along the slip plane from one lattice site to the next and those ahead of the dislocation have hardly begun to move. Those at the centre of the dislocation have slipped halfway; as they complete their slip they push the next row of atoms along the dislocation line into the half-slipped position. In this way the dislocation moves forward and the crystal slips.

The ability of a dislocation to glide depends on the forces between atoms at its centre. In simple metals the atoms, which may be pictured as small spheres, are not joined directly by chemical bonds but are pulled together by free electrons that move through the spaces between them. It is not difficult for these atoms to slide over each other in a dislocation, since no chemical bonds have to be broken; and so the dislocation is mobile. But in a nonmetallic crystal such as diamond or quartz in which the atoms are joined directly by chemical bonds the difficulty of breaking and re-forming these bonds makes it hard to move a dislocation except at high temperatures where the heat motion of the atoms is strong enough to break bonds. This explains why a metal such as copper or aluminum is malleable at all temperatures, whereas many non-metallic crystals are brittle except at high temperatures. The free-electron structure is not sufficient by itself to ensure that a crystal is soft and malleable; the crystal structure also plays a part. This is shown by the fact that many intermetallic compounds (*q.v.*) which have complex crystal structures, *e.g.*, the compound  $\text{CuAl}_2$  formed between copper and aluminum, are hard and brittle despite the fact that they are held together by free electrons and are obviously metallic substances. The special feature about the simple, malleable metals is that the slip planes in them are unusually smooth, each consisting of a densely packed sheet of atoms widely spaced from the next sheet. Because of this, when one such sheet slides over another the cohesion between them fluctuates less violently than it does in most other types of crystal. The structures of the dislocations are also altered by this effect. In gold, for example, the highly strained central region of the dislocation is spread out over a region about 30 atoms wide in the slip plane, rather as in fig. 1 (A), so that the dislocation line is really a flat "ribbon" lying in the slip plane. In certain alloys such as some of the brasses and bronzes it is possible, by plastic working, to widen the dislocations out completely across the slip planes, so producing crystallographic stacking faults on those planes.

**Yield Strength.**—The yield strength of a malleable crystal depends on the forces needed to create dislocations in it and to glide these dislocations against the resistance of various obstacles that exist in the material. In pure, unworked metals slip is produced by the application of extremely small forces, when the crystal lattice is sheared elastically through an angle of only about  $0.001^\circ$ . It is quite impossible to create dislocations in a perfect lattice by straining it as gently as this. In fact it is clear, by considering diagrams such as fig. 6 (A), that the atoms would have to be pushed forward a distance which is a large fraction of the interatomic spacing before they would consent to run on of their own accord to produce a configuration such as that of fig. 6 (C). The lattice would thus have to be sheared elastically

BY COURTESY OF DR. A. H. COTTRELL

FIG. 8.—STAGES OF SLIP PRODUCED BY THE GLIDE OF A DISLOCATION ALONG A SLIP PLANE

through an angle of about  $10^\circ$ . From the known elastic properties of, say, copper, the shear force needed for this is about 1,000,000 lb. per square inch of slip plane area.

The exciting prospect of producing materials with such high strengths as this stimulated much research. C. Herring and J. K. Galt showed in 1952 that pure tin, normally one of the softest of metals, becomes stronger than steel when prepared in the form of whisker crystals. Since then it has been shown that whiskers of most substances are extremely strong; iron and graphite whiskers for example have withstood stresses of 1,700,000 and 3,000,000 lb per square inch. It seems that such whiskers have either no dislocations in them or none in those configurations that enable large amounts of slip to form. Large perfect crystals free from dislocations have also been grown and these again are extremely strong.

**The Frank-Read Source.**—The softness of ordinary malleable crystals is due to dislocations already present in them or to other imperfections from which dislocations are easily created. As explained above, under certain conditions crystals will not grow unless they contain dislocations. Dislocations can also be created by thermal shrinkage strains, particularly around specks of foreign substances included in the crystal, as well as by the impact of grit on the surface. Several methods for observing dislocations inside crystals have been developed. In 1953 J. M. Hedges and J. W. Mitchell succeeded in revealing dislocation lines inside silver bromide crystals by "decorating" them with specks of metallic silver. In 1956 P. B. Hirsch, using a transmission technique with an electron microscope, succeeded in filming dislocations in motion inside thin aluminum foil. His method has been applied widely to the study of dislocations in metals and other crystals. Later developments, due mainly to J. W. Menter, have enabled the atomic structure of dislocations to be resolved in some substances.

FIG. 7.—PLAN VIEW OF A SLIP PLANE IN WHICH A FRANK-READ SOURCE PRODUCES A DISLOCATION RING BY EXPANDING THROUGH A SEQUENCE OF POSITIONS 1, 2, 3, 4-5 ABOUT ITS NODES (A) AND (B)

eliminate them completely at any temperature below the melting point of the material.

A remarkable geometrical property of such networks, discovered in 1950 by F. C. Frank and W. T. Read, is that large numbers of dislocations can be created from certain places in a network by the application of small forces. Fig. 7 represents a plan view of a slip plane containing a Frank-Read source; *i.e.*, the dislocation line 1 lying between the fixed nodes A and B. A shear force applied to the plane causes this dislocation to glide across it. Being held at its nodes, the dislocation line must bend into approximately circular shapes, *e.g.*, positions 2 and 3, as it glides. Eventually the branches of it which sweep behind the nodes meet and coalesce immediately after position 3, and produce a closed dislocation ring, 4, together with another line, 5, bridging the nodes. The ring 4 can expand to sweep over the whole slip plane, so producing one unit of slip, and the line 5 can repeat the entire sequence that started with line 1. There is thus a virtually unlimited production of dislocation rings on the slip plane of the Frank-Read source. This process, which has been confirmed by observations in silicon crystals by W. C. Dash (1956), is widely accepted as one way in which slip bands are formed; *i.e.*, bands of intense slip, involving thousands of dislocations, formed on certain slip planes in a plastically deformed crystal. It is not always necessary that dislocations be linked in a network for slip bands to

Such observations have shown that dislocation lines are often linked together in networks reminiscent of the networks formed in a soap froth by the lines where three soap bubbles meet. Each dislocation line, typically about 0.0001 cm. long, is joined to others at "nodes" in the network and so is constrained from moving completely independently of them. As a result, the network as a whole has a mechanical stability analogous to that of a soap froth. This is why it is almost impossible, once dislocations have been formed in a crystal, to

FIG. 8.—MULTIPLICATION OF SLIP DISLOCATIONS BY THE CROSS-SLIP OF PART OF AN EXPANDING DISLOCATION RING, FIRST ONTO A PLANE (AB) AND THEN ONTO ANOTHER PLANE PARALLEL TO ITS ORIGINAL SLIP PLANE

parallel to the slip direction. As shown in the figure, an expanding dislocation ring may, by double cross-slip, transfer part of itself to a nearby parallel plane. A type of Frank-Read source is then created on both planes. This process, occurring repeatedly along a slip plane, produces a broad slip band dense with dislocations.

**Work Hardening.**—Most metals owe their plastic strength to obstacles which oppose the movement of dislocations. A great deal of metallurgical research is aimed at exploiting this principle. Among the more important of such obstacles are the dislocations themselves, which obstruct one another. This leads to the paradoxical fact that, although a metal is severely weakened by the first few dislocations formed in it, its strength improves again as more dislocations are added. As in road transport, dense traffic moves slowly. The simplest way to increase the density of dislocations in malleable solids is by plastic deformation, which generates dislocations by processes such as those of fig. 7 and 8. This leads to the well-known work hardening, an important means of strengthening many industrial metals and alloys by rolling, drawing and other processes of mechanical working. Yield strengths exceeding 300,000 lb. per square inch are produced in some steels by cold working. Experiments on single crystals of metals have shown that, provided slip occurs on only one family of parallel planes, there is not much work hardening. It is thus possible to stretch a single crystal of, say, cadmium to more than ten times its original length easily between the fingers. Work hardening occurs intensely when slip takes place simultaneously in different directions on two or more intersecting families of planes. Because of their cubic crystal structures metals such as copper, iron and aluminum commonly deform in this manner. Dislocations gliding in such planes interfere with and obstruct one another in several ways when they meet at the intersections. They may either attract or repel one another through the mutual effects of their elastic strain fields. They may lie across one another's paths, so that one dislocation line cannot advance without cutting through the line of the other. When these lines touch they may unite to form networks and new types of dislocations geometrically incapable of gliding. The general result is that the dislocations at such intersections become mutually locked together. Only at temperatures above about one-half of the absolute melting point, where the intense heat motion enables atoms to move about individually inside the crystal and anneals the obstacles, is it possible to reduce this work hardening substantially. At such temperatures the highly dislocated crystals are rapidly replaced by new, soft ones in a process of recrystallization and the material remains soft even while it is being plastically deformed. This is exploited in the industrial process of hot working. Pure lead and tin recrystallize even at room temperature, which is why they are so soft.

A basic process involved in the annealing of cold-worked crystals is the climb of edge dislocations, illustrated in fig. 9. Atoms jump onto the edge of the "half-plane" of the dislocation and raise it from one glide plane to the next. The atomic-sized holes or vacancies left by these atoms migrate into the crystal through the movements of other atoms

form and in certain cases a single dislocation line is sufficient. Such a process, first discussed by J. S. Koehler (1952) and E. Orowan (1954) and since confirmed in lithium fluoride crystals by W. G. Johnston and J. J. Gilman (1960), is illustrated in fig. 8. It depends upon the fact that a screw dislocation can cross-slip from one slip plane to another, provided all such planes are

into them and are eventually annihilated on the edges of other dislocations or at the surface.

If two nearby dislocations have half planes which extend in from opposite sides of the crystal, the edges of these half-planes may climb toward each other and eventually coalesce, so producing one whole plane and a perfect crystal in a region where two half-planes and two edge dislocations previously existed. This is one way in which the density of dislocations is reduced by atomic movements during annealing. Another process, which occurs in plastically bent regions of the crystal where all the half-planes extend in from the same side, is shown in fig. 10. By both climbing and gliding, the dislocations can align themselves systematically into a vertical wall or boundary. The plastic curvature is then removed from most of the crystal, becoming concentrated in the boundary across which there is a sharp change in the direction of the crystal axes.

The study of this polygonization process and of dislocation boundaries provided some of the earliest evidence in support of the theory of dislocations (R. W. Cahn, 1947; W. T. Read and W. Shockley, 1950; J. Washburn and E. R. Parker, 1952). The dislocation structure is clearly discernible in boundaries across which the crystal axes are rotated through small angles. At angles greater than about  $10^\circ$ , however, the dislocations lie so closely together in the boundary that they produce a practically continuous layer of misfitting atoms along the boundary, analogous to a monolayer of liquid between the two crystals. This is the structure of typical grain boundaries such as are found in polycrystalline metals and alloys as ordinarily used in industry. Grain boundaries obstruct slip dislocations very strongly but the direct hardening caused by them is small because they are widely spaced obstacles, judged on the scale of most dislocation processes. The crystal grains in a typical industrial metal, for example, are about 0.01 cm. across. The main effect of grain boundaries is an indirect one; the plastically deformed grains are forced to slip on several intersecting glide planes in order to continue adhering together across their boundaries.

FIG. 10.—FORMATION OF CRYSTALLITES IN A PLASTICALLY BENT CRYSTAL BY THE REARRANGEMENT OF EDGE DISLOCATIONS

**Alloying.**—The most important method of hardening metals is by alloying; that is, by adding other substances to them, either dispersed atomically through the crystal lattice or grouped into precipitates or small grains embedded in the main crystal grains. Most foreign atoms contained in a crystal are generally slightly too large or too small, by about 10% or so, for the atomic sites they occupy and are thus centres of lattice strain. Such atoms can fit better into atomic sites near the centre of an edge dislocation because the distorted lattice which exists there, as shown in fig. 9 (B), provides sites both larger and smaller than average. It follows that foreign atoms which expand the crystal are attracted to the expanded side of the dislocation, and vice versa. This attraction causes foreign atoms to segregate to dislocations at temperatures at which such atoms are able to migrate through crystals.

The effect is particularly important in mild steel because the carbon and nitrogen atoms in this material exist in the interstices between the metal atoms and can move through the crystal unusually rapidly along these interstitial channels. At room temperature, for example, such an atom makes about one jump per second from one interstitial site to the next. This means that, whenever a dislocation rests for a few minutes or hours at room temperature,

BY COURTESY OF DR. A. H. COTTRELL

FIG. 9.—CLIMB OF AN EDGE DISLOCATION BY THE CAPTURE OF NEIGHBOURING ATOMS, LEADING TO THE CREATION OF LATTICE VACANCIES

a swarm of carbon and nitrogen atoms move into it and take up positions of best fit near its centre. This is the process known usually as strain-age hardening or strain ageing. During the initial stages of ageing the interstitial atoms are distributed diffusely, forming an "atmosphere," along the dislocation lines. More prolonged ageing, particularly at a higher temperature, such as 200° C., causes the atmosphere to become so dense with segregated interstitial atoms that precipitation takes place and the dislocation lines then become decorated with small specks of iron carbide and other precipitated particles strung along them like beads on a necklace.

The mechanical properties of mild steel are profoundly affected by carbon and nitrogen ageing. A dislocation which is embedded in a swarm of interstitial atoms, whether as an atmosphere or a precipitate, is firmly locked in position by them and strong applied forces are needed to drag it away. On the other hand, as soon as it has moved a few atomic spacings away, it enters comparatively "clean" regions of the crystal and the force needed to continue its motion then falls spectacularly. This locking of dislocations by ageing, and unlocking only at high stresses, leads to many characteristic properties of steel. Until really large forces are applied the dislocations are so completely anchored by the interstitial atoms as to make aged steel one of the most perfectly elastic of all the malleable metals. The deviations from true elasticity which many other metals show under applied forces below their yield strengths, due to small movements of free lengths of dislocations between widely dispersed obstacles, can be completely suppressed. This is important in connection with the use of steel for springs and for wires in pre-stressed concrete. It may also account for the fact that steel, unlike other common metals, possesses a definite fatigue limit under oscillating forces. When a sufficiently large force is applied to aged steel the yield point is eventually reached. At this point free dislocations are produced which move and multiply rapidly, so producing a sudden burst of plastic deformation. As shown in fig. 11, the metal becomes softer when yielding occurs, due to the rapid multiplication

FIG. 11.—YIELD POINT OF AGED STEEL

of mobile dislocations inside it, and the force supportable by it falls from the upper yield point A to the lower yield point B. There then follows a period of deformation under constant load, through the yield elongation, before the work-hardening curve is reached at C. The original yield strength is not regained until point D is reached. In a tensile bar, for instance, the plastic elongation needed to reach this point amounts typically to about 2%. It follows that, when such a bar is made to support a con-

stant load at the level of the upper yield point, once one section of the bar begins to yield it must continue to do so until it reaches the point D in order to continue supporting the load on it. The plastic deformation of yielding steel is thus extremely non-uniform. Completely unyielded sections can exist next to other sections that have yielded and strained plastically by some 2%. Bands of differently deformed material, known as Lüders bands or lines, or stretcher strains, form across the material and are made clearly visible by changes in surface level caused by the difference in strain between them. These irregular bands of deformation are a source of trouble in the pressing of steel sheet and various steps are taken to avoid them. One method, known as temper rolling (a term sometimes also applied to cold rolling to stiffen a sheet) or leveler rolling, involves pre-straining the metal before pressing, to overcome the yield point everywhere in it. If the pressing is then made quickly afterward, before strain ageing has caused the yield point to return, a smoothly pressed sheet can be produced: various non-ageing steels are also made. In general carbon is less soluble in iron than is nitrogen and can be made relatively unimportant in strain ageing by precipitating it in large

particles during a preliminary heat-treatment. Nitrogen, being more soluble, is dealt with differently, by adding substances such as aluminum, manganese and vanadium, which have an affinity for it and "fix" it in the lattice, so preventing it from reaching the dislocations during strain ageing. At higher temperatures e.g., 400° C.–600° C., these metallic alloying elements become mobile and able to migrate themselves, with the carbon and nitrogen, to dislocations. Strain ageing due to the precipitation of alloy carbides and nitrides in dislocations thus appears in many steels of this type at elevated temperatures. The metal then retains or even improves its strength at such temperatures. This is the principle underlying some types of creep-resistant alloy steels, notably those containing 0.5% molybdenum which are used for superheater tubes and pipes in steam power plants. Niobium, which forms precipitates of niobium carbide on dislocation lines, has been added to high-alloy steels to improve their strength at high temperatures.

Many alloys, including the age-hardening aluminum alloys, are hardened by the formation of large numbers of finely precipitated particles dispersed throughout the crystal grains. Some of these particles are precipitated on dislocation lines but most are distributed randomly throughout the crystal lattice. The hardening in this case is due to the difficulty the dislocations have in moving past the many precipitates they meet as they glide in their slip planes. Since this is a dispersed form of hardening which opposes a dislocation throughout its entire glide motion, the material does not become markedly softer at the instant of yielding. N. F. Mott and F. R. N. Nabarro first explained, in 1947, how precipitation hardening could originate from localized stress fields around the precipitated particles, which oppose the stress field acting on the dislocations from the applied force. A. Kelly (1959) and R. B. Nicholson (1959) have shown that dislocation lines actually cut through the very fine precipitates and that an important contribution to precipitation hardening comes from the resistance these particles offer to cutting. If the precipitation process is allowed to proceed too far, as in over-ageing, the numerous fine precipitates are then replaced by a smaller number of coarse ones and the spacing between these becomes sufficiently large to allow the dislocation lines to pass between them. The material is then soft. This over-ageing is important in those creep-resistant alloys that depend for their strength on finely dispersed particles, since at high temperatures atoms migrate rapidly in the crystal structure and can readily cause the particles to coarsen. One of the aims in such alloys is to form particles that remain stable at high temperatures; e.g., aluminum oxide in aluminum, a nickel-titanium-aluminum compound in nickel, and alloy carbides in cobalt and high-alloy steels.

**Fractures.**—Although dislocations generally prevent malleable solids from fracturing by making them soft, they also contribute in several ways to processes of fracture. Highly ductile materials fracture under tensile forces when the dislocations in them cannot produce any more work hardening; the material then has no further protection against the enlargement, by localized plastic flow of holes or other geometrical irregularities in it. In more brittle crystals fracture is sometimes caused by the rapid "piling-up" of dislocations at intersections of their own slip planes with grain boundaries or other slip planes. Examples of such fractures have been observed in ionic crystals such as magnesium oxide. There is evidence to suggest that the brittleness of some steels at low temperatures is due to similar processes, related in this case to the interstitial locking of dislocations and to the creation of deformation twins. In fatigue deformation the dislocations glide forward and backward in their slip planes with the oscillations of the applied load and this causes sandwiches of material in slip planes to slide in or out of the crystal. At the surface of the specimen this material may move out, to form an "extrusion" standing above the surface, or move in, to leave a groove behind which eventually becomes a fatigue crack.

**CSÁRDÁS** or CZARDAS, Hungarian national dance in  $\frac{3}{4}$  or  $\frac{2}{4}$  time, in two parts: slow (*lassu*), played andante maestoso, and quick (*friss*), played allegro vivace. A ballroom dance adapted from the csárdás is popular in eastern Europe. As a character dance in ballet, the csárdás is danced with complicated, theatricalized Slavic and Hungarian folk dance steps, as in Delibes' *Coppélia* and Tchaikovsky's *Swan Lake*. (LN. ME.)

**CSOKONAI VITÉZ, MIHÁLY** (1773–1805), born in Debrecen, Nov. 17, 1773, was the most outstanding Hungarian poet of the 18th century. Throughout his life, he had to contend with uncommon difficulties. First an assistant master in his own old Calvinist college at Debrecen, he was soon dismissed, and lived thereafter as a wandering poet. For the sake of a wealthy girl (the "Lilla" of his poems) he tried to secure a permanent post, but by the time he had obtained a deputy mastership in a small town she had already married. Csokonai returned to Debrecen a poor man and a consumptive, and died there (Jan. 28, 1805) without having seen his poems published.

Csokonai had a great interest in form: he was one of the first Hungarian theorists of prosody, and the first to unite with ease Hungarian forms and the rhymed metrical ones of western Europe. His poetry breathes the spirit of the Enlightenment, of the abortive Hungarian Jacobinism. It is vigorous, often ironical, sometimes sentimental. His poems have a graceful musical charm and often also the savour and humour of peasant songs. He was also the author of plays, and of the first Hungarian comic epic, *Dorottya* (1804), a work influenced by Pope but nevertheless Hungarian in form and content.

Csokonai's collected works were edited by I. Harsányi and J. Gulyás, 3 vol. (1922). (N. KI.)

**CSOMA DE KÖRÖS, ALEXANDER** (1784–1842), or, as the name is written in Hungarian, KÖRÖSI CSOMA SÁNDOR, Hungarian traveler and philologist, was born April 4, 1784, at Körös in Transylvania to a poverty-stricken noble family. He was educated at Nagyenyed and at Göttingen. In 1820 he set out for the east to investigate the origin of the Magyars. He visited Egypt and then disguising himself as an Armenian he crossed central Asia to Tibet, where he spent four years in a Buddhist monastery studying the language and the Buddhist literature. His knowledge of Tibetan obtained him employment in the library of the Asiatic Society of Bengal, which possessed more than 1,000 volumes in society of Bengal, which possessed more than 1,000 volumes in Tibetan; and he was afterward supported by the government of Bengal while he published a Tibetan-English dictionary and a Tibetan grammar (1834). He also published an analysis of the Buddhist sacred books, the *Kanjur* (*bKah-hgyur*). The Hungarian government granted him a pension which he devoted to the purchase of books for Indian libraries. He spent some time in Calcutta studying Sanskrit and several other languages; but, early in 1842, he commenced his second attempt to discover the origin of the Magyars. He died at Darjeeling on April 11, 1842. An oration was delivered in his honour before the Hungarian academy by József Eötvös, the novelist.

**CTENOPHORA**, a phylum of unusual marine animals that look like small, clear, ovoid balls of jelly. They are commonly known as comb jellies, sea gooseberries, sea walnuts or cat's eyes. See COMB JELLY.

**CTESIAS** (fl. early 4th century B.C.), Greek physician and historian, was the author of *Persica*, a history of Assyria and Persia, based on Persian authorities. Born at Cnidus in Caria, he was in early life physician to Artaxerxes Mnemon, whom he accompanied (401) on his expedition against his brother Cyrus the Younger. Ctesias was also the author of treatises on rivers and on the Persian revenues, and of an account of India. The *Persica*, written in the Ionic dialect, was professedly founded on the Persian royal archives. The first six books treated of the history of Assyria

and Babylon to the foundation of the Persian empire; the remaining 17 went down to the year 398. Of the two histories there are abridgements by Photius, and fragments in Athenaeus, Plutarch and Diodorus Siculus, whose second book owes much to Ctesias.

As to the worth of the *Persica* there has been much controversy. Being based upon Persian authorities, it was naturally looked upon with suspicion by the Greeks and regarded as untrustworthy, a view which, even when allowance is made for the condensation of Photius, seems likely to be right.

**CTESIPHON** (TUSBUN, TAYSAFUN), an ancient city on the Tigris river, 20 mi. S.E. of Baghdad, in central Iraq. Winter capital of the Arsacid (Parthian), later often of the Sasanian empire (see PERSIAN HISTORY), the site is famous for remains of a gigantic vaulted hall, the Taq-e Kisra, traditionally regarded as the palace of Khosrau I, though Shapur I also undertook work on the site. First mentioned by Polybius in 221 B.C., Ctesiphon was originally a Greek army camp on the east bank of the Tigris opposite Seleucia. Air survey shows that in modern times the course of the river has shifted, no longer flowing between the cities but dividing the site of Ctesiphon. When in 129 B.C. the Arsacids finally annexed Babylonia, they found Ctesiphon a convenient residence and cantonment. As this royal suburb of Seleucia grew, the two came to form a twin city, a status symbolized by coins issued soon after 31 B.C. showing two city-goddesses joining hands over an altar. Ammianus' statement that Ctesiphon was "founded" by a king Vardanes, then enlarged and fortified by Pacorus, is of uncertain interpretation; yet its typically Parthian circular plan contrasts with the rectangular layout of Greek Seleucia. Roman occupations of the twin capitals began with the emperor Trajan in A.D. 116. In the sack of both by the Roman general Avidius Cassius in A.D. 165, the Arsacid palace of Ctesiphon was destroyed and Seleucia depopulated, an event which extinguished local Greek culture. Septimius Severus, entering Ctesiphon in A.D. 197, found Seleucia abandoned. As late as A.D. 283 Ctesiphon was briefly occupied by the emperor Carus. The Sasanian monarchy finally replacing the Arsacid in A.D. 228 greatly favoured Ctesiphon, though Ardashir I also resettled the west bank to found Veh Ardashir (Arabic, Bahurasir). Farther east Asfanabr, site of the Taq-e Kisra, and Veh-Andiokh-Khosrau (Arabic, Al Rumiya), a settlement for the Roman captives of Khosrau I, were other Sasanian suburbs.

The Arabs in A.D. 637 conquered this city-complex, called by them Al Mada'in (the capitals), obtaining immense booty. At first they used the Taq-e Kisra as an improvised mosque. Its splendid murals survived until the 9th century A.D. It was at Al Rumiya that the caliph al-Mansur executed his lieutenant Abu Muslim, but when in 763 he founded Baghdad, Ctesiphon was deserted except as a quarry for building material.

During World War I a battle, preceding the siege of Kut, took place on the site of Ctesiphon between British and Turkish armies (1915). (A. D. H. B.)

**CUANZA**: see KWANZA.

**CUANZA NORTE**, a district of the Portuguese overseas province of Angola, west Africa, is divided from Cuanza Sul district by the Cuanza river. Pop. (1960) 263,101. Area 12,050 sq.mi. The district has five *concelhos* (counties); the capital is Vila Salazar. Cuanza Norte is rich in mining and agriculture. Manganese ore (Cazengo and Golungo Alto), iron ore (M'Bassa, near Zenza do Itombe) and bituminous coal are extracted. Agricultural production is varied but the main products are coffee, sisal, palm oil, palm kernels, peanuts, castor beans, tobacco, cotton, broad beans and cereals. There are also minor industries: the preparation of coffee, cotton and sisal, the extraction of oils and the making of soap. At Cambambe a dam was begun, designed to produce 1,300,000,000 kw. of electric power. The region has a remarkable beauty of landscape. The railway and road from Luanda to Malanje pass through the south of the district.

(A. A. G. P.)

**CUANZA SUL**, a coastal district in the Portuguese overseas province of Angola, west Africa. Pop. (1960) 405,012. Area 17,317 sq.mi. The district (capital, Novo Redondo) has seven *concelhos* (counties). There is profitable fishing at Porto Amboim and Novo Redondo. The main agricultural products are coffee, cotton, sisal, palm oil, palm kernels, peanuts, sesame and castor beans, tobacco, crude rubber, broad beans and cereals. Stock is intensively bred. Land is exploited chiefly by big companies, although cereals, cotton and some of the coffee are produced by Africans. Industries include the preparation of coffee, cotton and sisal; the production of fish oil and meal; the extraction of vegetable oils; milling; the production of soap and ceramics; dairying and meat preserving. Porto Amboim is served by a railway to Gabela (80 mi.) which carries the products of the interior.

(A. A. G. P.)

**CUBA**, the largest and most populous island in the Antilles, more commonly called the West Indies. Together with the Isla de Pinos (1,182 sq.mi.) and more than 1,600 offshore islets and keys which are included in the national territory, Cuba's total area is 44,218 sq.mi. This represents more than half the area of the entire Antillean chain. The shape of the main island is long and narrow, resembling an irregular crescent convex to the north. Its length along an east-west axis from Cape Maisi to Cape San Antonio measures about 746 mi.; its breadth averages about 62 mi. but varies from a minimum of 22 mi. to a maximum of 124 mi.

Cuba is strategically located at the entrance to the Gulf of Mexico, between the parallels 19° 49' and 23° 15' N., and the meridians 74° 8' and 84° 57' W. This location has been significant in both the historical and the economic development of the island. During the colonial period, Cuba's commanding position at the entrance to the Gulf and Caribbean astride the sea lanes to Mexico, the Isthmus of Panama and other important points made the island so valuable that the Spaniards referred to it as the "key to the new world." After its independence, Cuba's proximity to the great population centres and markets of the eastern United States was a major factor in its economic growth. Since 1960, its alignment with the Soviet Union has changed its economic orientation.

## I. PHYSICAL GEOGRAPHY

**1. Geology and Structure.**—The geological history of the physical features of Cuba is a complicated one. The foundation of

the island is composed of metamorphic and igneous rocks such as schist, slate, marble and granite of pre-Cretaceous Age. Several periods of crustal disturbance occurred from Late Jurassic time. Periods of more or less intense folding and uplift alternated with periods of subsidence of the island, accompanied by the deposition of several thousands of feet of strata. A period of intense folding along approximately 350 mi. of the northern coast occurred in the Late Cretaceous, accompanied by a considerable amount of volcanic activity that resulted in thick series of tuffs, volcanic breccia and flows. The folding of the Eocene was the most intensive as well as the most widespread, of the periods of deformation. Thrusts and overturned folds occurred in western, central and eastern Cuba, and basaltic flows in the east.

The last period of folding occurred after the deposition of the Middle Miocene, about 20,000,000 years ago, and developed along the structural lines of the earlier foldings. Cuba was raised above sea level and was united with the other Antilles. Following the last folding a sharp uplift resulted in widespread faulting. The most striking fault zone was that of the large fault block of the Sierra Maestra of southeastern Cuba, which was tilted toward the north and was separated from the islands to the southeast by the very deep Bartlett trough.

Later, in the Pliocene period, erosion reduced a large part of Cuba almost to a plain. A slow, irregular emergence in the Pleistocene caused marine terraces that now mark the island's coast line, especially at the eastern end. The Recent period, which includes the last 50,000 years, has been characterized by slight coastal emergence in some areas and submergence in others. Most of the pouch-shaped embayments, which make excellent harbours, were formed during this period, when slight submergence inundated the mouths of rivers.

Cuba is still subject to some crustal instability, and several destructive earthquakes have been recorded, such as at Santiago de Cuba in 1578 and 1678. The zone of maximum instability is along the northern escarpment of Bartlett trough, where the Sierra Maestra rises abruptly from the sea, and light seismic disturbances are felt every year.

The general structure of Cuba is broadly anticlinal with several systems of folding superposed on the broad arch. The southern flank is wider and gentler in dip than the northern one. A chain of low anticlines runs in echelon through the island along trends of structural weakness that are roughly parallel to the west-east axis of the island itself.

Most of the soils have been derived from limestone and have a high clay content. Typical of these is the famous Matanzas red clay, the leading soil used for sugar cane. Alluvial soils are extremely fertile but are confined to narrow flood plains of the streams.

**2. Physiography.**—Most of Cuba consists of gentle slopes and rolling land. Mountains cover about one-fourth of the total area and are widely spread from one end of the country to the other, with large plains areas between mountain concentrations. The fact that nearly three-quarters of its terrain consists of relatively level land is significant for agricultural utility, particularly in facilitating cultivation and transportation.

The characteristics of the present relief of Cuba are the result of the interaction of two groups of forces. The constructive, or orogenic, forces have determined the structure and alignment of the land forms, while the destructive, or erosive, forces, such as water, winds and waves, have sculptured the original structure into the present forms.

The alignment of Cuban land forms consists of four principal wings arranged in echelon, like a series of steps. The northernmost wing is a long, asymmetrical folding, much worked by erosion, which extends from western Pinar del Río into the northern sections of Havana and Matanzas provinces. The Havana-Matanzas section consists of two low anticlines separated by a syncline—all arranged in an east-west direction. The Pinar del Río section, however, has had such pressures applied that folds were overturned and old rocks rest on top of younger rocks in places. The second wing, at the centre of the island, is a complex system of igneous intrusions in the centre of Las Villas and of overturned folds in

the southern part. The third wing, from Camagüey into northern Oriente, consists of folded structures and serpentine intrusions, but most of the region has been reduced by erosion to the condition of a peneplain (almost plain). The fourth or southernmost wing is a complex area of folding, large domal intrusions and plateau structure in the extreme east, and the great fault block of the Sierra Maestra rising sharply out of the sea.

The average elevation of Cuba is reported to be about 325 ft. above sea level. The highest elevation is 6,578 ft. at Pico Turquino in the Sierra Maestra, and a considerable part of the mountainous region of extreme southeastern Cuba lies above 2,000 ft. Highest elevations in Camagüey are just over 1,000 ft. In the Trinidad mountains of southern Las Villas the highest peak is 3,800 ft. The highest elevation in Pinar del Río is 2,389 ft., near the north coast.

More than 200 rivers drain the surface of Cuba. Most of these run toward the north or toward the south, dividing approximately along the axis of the island. Many of the rivers empty into wide, deep estuaries that allow navigation for a short distance from the coast line. Because of the narrow width of the island, almost all of the rivers are short. The largest is the Cauto, 155 mi. in length, which runs parallel to the Sierra Maestra through the wide plain of western Oriente.

Cuba's coast line of approximately 2,200 mi. has an extraordinarily large number of good harbours, chief of which are the pouch-shaped or bottlenecked harbours, which have narrow entrances but commodious anchorage. The main bays of this type are Honda, Cabañas, Mariel, Havana, Nuevitas, Puerto Padre, Nipe and Tánamo on the north coast and Guantánamo, Santiago de Cuba and Cienfuegos on the south coast. The principal open bays are Matanzas and Cárdenas.

**3. Climate.**—Cuba's insular position near the northern limit of the tropics results in a climate that can be described as maritime subtropical, but variations from this type are common. The fact that no place is far from the sea has a moderating effect on the temperature, but the effects of elevation and of exposure to predominant winds are also felt.

The fundamental characteristic of the temperature is its relative uniformity during the year and from year to year. Mean temperatures range from 70° F. in January and February to 81° in July and August, decreasing, of course, with elevation. Extremes are greatest in the interior. Maximum temperatures above 90° are rare; minimum temperatures below 50° are equally rare except in the mountains, where freezing temperatures are occasionally recorded. Coastal areas are moderated noticeably by the trade winds, which are steady throughout the year, blowing from the northeast in the winter and from the east to southeast in the summer. Occasional masses of cold air from the continental United States in the winter affect the northern coast of Cuba.

Since temperature is a relatively uniform characteristic of the climate, rainfall is the most important climatic element in Cuba. Rainfall is abundant, averaging 54 in. annually for the island as a whole. The wettest part of the island, averaging more than 65 in., is the mountainous section of Pinar del Río. The driest place, averaging less than 30 in., is in the basin of Guantánamo on the leeward, southern coast of Oriente. Throughout Cuba there are two seasons: the rainy season and the dry season. The rainy season, corresponding to the high-sun period of intense convection, extends from May to November, during which about three-fourths of the yearly rain falls. Actually, two distinct maxima are evident during the rainy season. The June maximum is caused by the daily thunderstorms of the period of vertical sun; the September maximum is related to the hurricanes.

Cuba is situated in a zone frequented by tropical cyclones, or hurricanes. Such storms may occur at any time from June to November but are commonest in September and October. Seldom does a decade pass without hurricanes of at least local severity. Since they measure as much as 400 mi. in diameter, their effects are felt widely. High wind velocities and heavy rainfall, as well as wind-driven waves, may destroy houses, crops, shipping and even human life. The probability of hurricanes increases from east to west, being highest in Pinar del Río and lowest in Oriente.

**4. Vegetation.**—Climatic and soil conditions of Cuba make possible a flora of splendid richness, comprising characteristic species of the West Indies, southern Florida, Mexico and Central America. The total number of native flowering species has been estimated at between 5,000 and 6,000. In addition, much of the original vegetation cover has been replaced by many exotic cultivated plants, particularly sugar cane, coffee, cacao and bananas.

Large forests of valuable woods covered the fertile plains of Cuba before the extension of agriculture. Almost all of the forests of the plains have disappeared, while much has been preserved in the mountain districts. As a result of the distinct seasonal nature of the rainfall, true tropical rain forests are found only in a small section of the eastern coast near Baracoa, where windward exposure to trade winds results in fairly well-distributed rainfall. Elsewhere, forests exhibit varying degrees of semi-deciduous formations. The principal zones of forest remaining are the mountains of Pinar del Río, Trinidad mountains, Sierra Maestra and the highlands of Baracoa and Nipe. Pine forests are fairly extensive in Pinar del Río, Isla de Pinos and the Nipe mountains of northern Oriente. The chief species that have been left standing in the heavily deforested plains are the royal palm and the ceiba. The stately royal palm (*Roystonea regia*), considered the national tree, attains a height of 50 to 75 ft. and sometimes of more than 100 ft., and every portion, from roots to leaves, serves some useful purpose. The beautiful ceiba (*Ceiba pentandra*), or silk-cotton tree, often grows to a height of 100 to 150 ft., with enormous girth and wide-spreading branches, and is an object of reverent fear to many rural inhabitants.

In addition to the pine and cedar, there are at least 40 choice cabinet and building woods, including oaks, mahogany, lignum vitae, ebony, granadilla, ácana and sabicu. Many species of woods are rich in gums and resins; others are oleaginous; and many are medicinal. There are also various dyewoods. More than 30 species of palms, including the coconut palm, are common features of the landscape.

Savannas, signifying a tropical landscape with few trees, originally covered about one-fourth of Cuba. The sparse vegetation is not the result of lack of rainfall but rather of the soils that are unable to retain sufficient moisture for a richer vegetation. Fairly large areas of sandy soils in southern Pinar del Río, western Las Villas and much of Camagüey are covered with poor grass, palms and woody shrubs.

Mangrove forests cover much of the extensive coastal areas, especially along the inundated southern coast.

Among the common fruits are custard apples (*Annona reticulata*), sweetsops (*A. squamosa*), soursops (*A. muricata*), star apples (*Chrysophyllum cainito*), papayas (*Carica papaya*), mamee apples (*Mammea americana*) and avocados (*Persea gratissima*).

**5. Animal Life.**—The main characteristics of Cuban fauna are (1) great richness and variety of species and varieties; (2) paucity of vertebrates; (3) profusion of lower species; (4) existence of species of small size; and (5) localization of species. Some species are limited or localized to a very small range.

Indigenous mammals include 23 species of bats, 6 species of rodents and 2 species of insectivores. The predominance of bats over land mammals is a phenomenon opposite to that which occurs on continents. Although some bats live in abandoned buildings and attics, the most numerous are those that inhabit the innumerable caves of the limestone regions and furnish valuable guano. The largest bat (*Noctilio leporinus mastivus*) feeds on small fish; the smallest is called the butterfly bat, subgenus of *Natalus*: *Nyctiellus lepidus*. Three species of large rats, one of which is in part arboreal (*Capromys prehensilis*), inhabit forested areas and are now relegated chiefly to the mountains. The *Solenodon cubanus* is a peculiar and very rare insectivorous mammal nearly two feet long. The manatee or sea cow frequents the mouths of rivers.

Birds recorded in Cuba number about 297 forms (species and subspecies). Only about 70 are indigenous. Many are familiar North American migrants, resident in the West Indies in winter. One of the most striking of the native types, the Cuban macaw, is extinct as a result of deforestation and agricultural expansion. The

distinctively American group of hummingbirds is represented by three species.

Reptiles and amphibians are few as compared with the Central American region, but there are numerous species of frogs and of lizards. The largest lizard is the iguana (*Cyclura macleayi*). There are two species of crocodile, one known as the cayman, the other as the *cocodrilo*. There is a common fresh-water turtle. Cuba has no poisonous snakes, though there are several kinds of small boas.

The marine fishes are those of the West Indian region in general, a rich tropical fauna with many brilliantly coloured types. Marine invertebrates include more than 4,000 species of mollusks. Cuba is especially rich in land snails.

Insect life is varied and abundant; 17,000 species are said to have been described. The near extinction in 1902 of *Aedes aegypti*, the mosquito that carries yellow fever, was one of the early triumphs of medical entomology. See YELLOW FEVER.

## II. GEOGRAPHICAL REGIONS

The landscapes of Cuba can be grouped into four major geographical regions on the basis primarily of relief. The resultant natural divisions reflect differences not only in physiography but also in other elements of the geographical landscape, such as vegetation, soils and human activities. The four regions thus distinguished are Occidente (comprising essentially the three western provinces), Las Villas (most of the central province), Camagüey (and the northwestern part of Oriente province) and Oriente.

**1. Occidente.**—The region of Occidente extends from westernmost Cape San Antonio to the savannas of Manacas in western Las Villas province, encompassing all of Pinar del Río, Havana and Matanzas provinces—about 26% of the national territory and about 40% of the nation's population.

Western Cuba exhibits two main zones of folding. One is prolonged from southwest to northeast along Pinar del Río; the other extends east to west in the north-central sections of Havana and Matanzas. The backbone of the westernmost section is the Sierra de los Órganos, a strangely beautiful landscape of haystacklike, brush-covered hills separated by numerous fertile, flat-floored valleys. Toward the east is the more rounded though higher (to 2,389 ft.) Sierra del Rosario, in whose high valleys is some coffee. On both flanks of the Sierra de los Órganos are pine-covered hills. From the longitude of Havana bay eastward extend three series of parallel heights, separated by long synclinal valleys. The northernmost series is very close to the north coast.

The northern plain of Pinar del Río is a narrow strip between the mountains and the coast, whereas the southern plain is relatively wide and slopes gently to the swampy coast. For the most part the soils of the southern plain are sandy and used mostly for pasture, except in certain sections where applications of fertilizer have produced the world-famous Vuelta Abajo tobacco. Rice, by means of irrigation, has become important in places.

The red plain of southern Havana and Matanzas contains some of the best soils of Cuba. The red clay soils of great depth and of excellent permeability yield great quantities of sugar cane, rice, pineapples, plantains, vegetables and other agricultural products. A considerable part of the agricultural production, especially around Güines, is aimed at the metropolitan Havana market.

The peninsulas of Guanahacabibes and of Zapata extend southward to the Caribbean. The westernmost, Guanahacabibes, is flat, little populated, and is in part extremely rocky and in part covered by swamps and lagoons. The Zapata peninsula is also very sparsely populated, consisting of vast areas of mangrove swamps surrounding the low, rocky axis of the peninsula. The chief activity is charcoal making.

**2. Las Villas.**—The region of Las Villas occupies the central portion of Cuba and encompasses almost all of the province of Las Villas, except the Zapata peninsula, and includes a small part of western Camagüey. Its area is approximately 20% of the national territory, and its population is about 20% of the nation.

Rising from the southern coast of Las Villas are the Trinidad mountains, where several peaks of more than 3,000 ft. elevation are found. The complexly folded structure of the mountains is

cut by an intricate system of drainage that has resulted in steep tortuous valleys in many places. Beautiful waterfalls, such as on the Hanabaniilla river, are fairly common. A few valleys are sufficiently large for intensive agricultural use. Coffee, sugar cane and tobacco are the main crops. The highlands continue east of the Agabama river as the Sancti Spiritus mountains, which are somewhat lower. To the north of the Trinidad mountains and slightly separated are the Santa Clara hills, which consist essentially of intrusions of granite and serpentine. Undulating relief and savanna-type vegetation have given rise to cattle raising and tobacco growing as the chief activities.

The northern section of Las Villas consists of a very low cordillera and a coastal plain of variable width. The hilly part is prolonged for about 125 mi. parallel to the coast and is highest at the eastern end, where it rises to 1,600 ft. The highly productive soils of the coastal plain and of the valleys of the Sagua la Grande and Sagua la Chica rivers form one of the nation's chief sugar-cane and tobacco regions.

Moderately extensive plains extend west and east of the Trinidad-Sancti Spiritus mountains. More than one-half of the fertile plain north of Cienfuegos bay is cultivated, and the density of population is very high. The sugar industry is the base of the economy. The plain extending from Sancti Spiritus to the Caribbean coast is also one of the most productive agricultural sections of Cuba. Its chief products are sugar, tobacco and dairy products.

**3. Camagüey.**—The region of Camagüey extends from the western part of the province to include the northwestern section of Oriente as far as Nipe bay. It contains more than one-fourth of the national territory but less than 20% of the nation's population. In general, Camagüey's relief is dominated by plains, with undulating sections and a few steep areas. Three areas of hilly relief can be distinguished. The so-called Sierra de las Cubitas in north-central Camagüey consists of a large overturned fold of hard limestone formations with the most notable caves in Cuba. A low, isolated hilly section also rises southeast of Camagüey city. The third hilly section is found in the extreme eastern part of the region between the coast line and the Cauto plain.

The undulating central plain extends from the city of Camagüey to Holguín. The area is one of extensive savannas with generally gravelly and sandy soils, except around Holguín where soils are heavier. The major activity is cattle raising on the extensive pastures, which support about one-fifth of all Cuban cattle. Chromite is mined in this section. Some sugar cane is grown, and the area around Holguín is a significant producer of beans and other staple foodstuffs for the nation.

The northern and southern coastal plains of Camagüey slope gently from the slightly upraised interior toward the coasts. Good soils predominate, and the production of sugar cane is the chief economic activity, supplemented by livestock raising in parts of the southern plain. The plains were sparsely inhabited until after the beginning of the development of the sugar industry about 1900. Several huge sugar mills grind the cane, making Camagüey the nation's leading sugar province.

The section known as La Trocha plain lies completely across the width of the island in western Camagüey. Its red clay soils are among the most productive in Cuba and are cultivated intensively for sugar cane, pineapples, oranges, potatoes, rice and other crops. Although isolated by lack of transportation facilities during the colonial period, La Trocha grew rapidly after 1905.

**4. Oriente.**—The region of Oriente includes the greater part of Oriente province, excluding the northwestern section. It comprises about one-fourth of the nation's territory and population.

Oriente presents the most rugged relief of Cuba, particularly as represented in the Sierra Maestra, which extends along the southern coast from Cape Cruz for about 150 mi. to Guantánamo basin. The fault-block range rises steeply and majestically from the depths of the Bartlett trough to heights of more than 6,578 ft. above sea level. The southern slopes are almost uninhabited, but the northern slopes are smoother, and the valleys are used for coffee. Manganese deposits are exploited. Much of the Sierra is covered by dense forests.

While in many respects race prejudice is not evident, it cannot be denied that it has an influence in determining social position.

Negroes are admitted freely to schools and the university, public restaurants and places of public assembly. Intermarriage is relatively common. Negroes are elected to congress, though usually not in proportion to their numbers. Yet they are underrepresented among professional and semiprofessional occupational groups, proprietors, managers and high officials, office workers and salesmen. They are overrepresented in proportion to numbers among skilled and unskilled workers and those providing personal services.

The revolution that brought Castro to power in 1959 has modified the class structure in at least two respects. First, the lower classes have been upgraded in the sense that the political power structure rests upon them. Second, the upper and middle upper classes have lost economic and political power, and a large proportion of them are now refugees abroad. (L. NN.)

#### IV. HISTORY

Cuba, discovered by Columbus in the course of his first voyage, on Oct. 27, 1492, was one of Spain's first footholds in the new world and was the last Spanish colony in the Americas to obtain independence. Colonialism has been an important mold of the island's history.

The conquest of Cuba was begun in 1511 by Diego Velázquez with a force of about 300 men and was completed in less than two years. By 1515 the Spaniards had established small settlements at Baracoa (the landing point), Bayamo, Santiago de Cuba, Puerto Príncipe (Camagüey), Sancti Spiritus and the original Havana. Velázquez' reputation and legends of wealth drew many immigrants to the island, but it was soon realized that Cuba was not the treasure house that had been imagined. The colony's first use for the Spaniards in the 16th century was as a steppingstone for the exploration and conquest of the adjoining mainland. From Cuba went the expeditions that discovered Yucatán (1517) and explored the southern Gulf coast of Mexico, and the expeditions of Hernán Cortés for the conquest of Mexico (1519-21) and of Hernando de Soto for the exploration of Florida and the lower Mississippi valley.

**1. Early Colonial Period.**—Following the period of exploration, Cuba's chief function within the Spanish colonial empire was to serve as a supply and communications base for the fleet moving to and from the new world. Havana became the principal port and naval base of Hispanic America. Ships bound for Spain assembled in the port to be convoyed in the eastern crossing of the Atlantic, and fleets from Spain for the Americas often called first at Havana. An agricultural economy developed, aimed at supplying both the needs of the local population and provisions for the ships that plied between Spain and the colonies. Cassava, sweet potatoes and plantains were grown, and cattle raising was started. At first the labour force for agriculture was supplied by poor Spanish-born and Creole farmers and by Indians. The institution of a plantation economy for the production of sugar and tobacco, coupled with the rapid destruction of the Indians, created a labour shortage, however, and warranted the importation of African slave labour. The first slaves began arriving as early as 1522, and these, reinforced by many thousands more, eventually made a significant contribution to the racial composition of the Cuban population. Throughout the colonial period Cuba's economic growth was severely handicapped by Spanish mercantilist policies. The colony was considered to exist only for the good of the mother country; trade with countries other than Spain was forbidden; all the island's commerce had to be carried in Spanish ships; the colony according to law could produce nothing that would compete with production in Spain. As a result of these restrictions, smuggling became an important means of bolstering the island's commerce.

Because of its strategic location and its role as a naval base and centre of communications, Cuba became an important target for the attacks of the European sea powers disputing the Spanish hold on the West Indies. Throughout the 17th century Cuba suffered from Spain's wars with England, France and Holland. Surrounded by enemy colonies, attacked by pirates and freebooters, its line of communications with Spain threatened after the destruction of Spain's Mexico fleet near Matanzas in 1629, the island suffered widespread destruction. In 1662 the English attacked and de-

stroyed Santiago; Remedios was sacked by the French in 1665; the English freebooter Henry Morgan attacked Puerto Príncipe in 1668. The peace of Rijswijk (1697) brought a temporary end to the attacks, but by the end of the 17th century the Cuban population numbered only 50,000, and its economy was badly strained.

Between 1700 and 1763 Cuba's plight showed little improvement. Spain's numerous wars continued to disrupt commerce and cause loss of life and property on the island; economic exploitation and monopolistic control by the mother country became worse; concentration of administrative control in the hands of the military and discrimination against Cuban-born Creoles in favour of the Spanish-born peninsulars fostered discontent. The island's misfortunes reached a culmination in 1762 when the English captured and looted Havana after a bitter siege. The city was returned to Spain the following year in exchange for the Floridas.

**2. Reforms and Reactions.**—Beginning in 1764 Cuba made notable progress. The strategic and economic value of the island having been proved, Cuba was given greater attention by Spain. Moreover, Spain governed the Louisiana territory, which it had acquired from France in 1763 and held until 1800, from Havana. With the arrival of competent officers, agriculture and education received a new impetus, commerce increased and age-old monopolies were suppressed. Formal establishment of commercial relations with the U.S. opened up new channels of trade. Hundreds of Spanish families migrated to Cuba from Spanish Santo Domingo when that colony was ceded to France (1795). Later, thousands of immigrants followed them from French Haiti when the Negroes revolted and assumed power. Most of these French immigrants settled in Oriente province, where their names are still found. Their coffee and sugar plantations converted the region from neglect to prosperity.

Under a succession of liberal governors at the end of the 18th century and in the first part of the 19th, when wars in Europe cut off Spain from its colony, Cuba became practically independent. Free commerce with foreigners—a fact after 1809—was definitely legalized in 1818 and confirmed in 1824. In 1810 Cuba elected deputies to the Spanish *Cortes* (parliament), and in 1817 the long-unpopular tobacco monopoly was abolished. Populations reported by the partial censuses of 1774, 1792 and 1817 were 161,670; 273,301; and 553,033, respectively.

Despite this progress, discontent and restiveness still ruled the island. It seems reasonable to assume that if Cuba had been part of the mainland it would have struck for independence in the first quarter of the 19th century as did the other Spanish colonies. The sharp distinction between Creoles and peninsulars, the growing discontent with political conditions in Madrid and a rising sentiment of nationalism were as strong in Cuba as on the mainland. Failure to move for freedom may be explained in part by lack of effective aid from the outside and in part by disagreement among the Cubans themselves as to what was the best course for the future— independence, autonomy within the Spanish empire or annexation to the U.S. As the 19th century progressed, however, desire for independence increased, helped to a major degree by renewed repressive measures of the Spanish government. These took the form of arbitrary powers granted in 1825 to the governor of Cuba to ward off the restiveness of the Cuban population and threatened invasions from Mexico and Colombia. Gov. Miguel de Tacón (1834-38) made matters worse by suppressing the popular Spanish constitution of 1834 soon after its proclamation in Cuba in 1836. In 1837 Spain excluded Cuban deputies from the Spanish *Cortes* and declared that Cuba (and Puerto Rico) would be governed by "special laws." Since the colony had no voice in the *Cortes* and the special laws were never passed, the arbitrary rule of the governor remained supreme.

The political scene in Cuba was further complicated at this time by the desire of certain groups in the U.S. to acquire the island. U.S. proslavery elements, especially, saw in Cuba the possibility of expanding slave territory to offset the growing power of anti-slavery forces in the U.S. congress. In the mid-19th century several freebooting expeditions from the U.S. failed to free Cuba while at the same time Presidents Franklin Pierce and James

Buchanan tried in vain to purchase the island from Spain.

Sporadic revolts increased in number until 1855. After a period of unsure peace, war broke out again in 1868. It was to be one of the longest (ten years) and bloodiest ever fought in the Americas.

**3. Civil Wars.**—The Ten Years' War, which brought death to more than 200,000 Cubans and Spaniards and caused much property damage, resulted from Spain's failure to bring badly needed reforms to Cuba. Proposals for the emancipation of the Negro slaves were indefinitely shelved by a committee appointed to bring about this reform. Taxes rose and the public debt soared. Military tyranny suppressed criticism of the corrupt and ineffective Spanish administration. When a junta of inquiry of Cuban and Puerto Rican delegates meeting in Madrid in 1866-67 failed completely to get action, Cuban leaders decided the time had come to strike. Some of them desired reforms only, such as the abolition of slavery; others wanted annexation to the U.S.; while a growing section wanted complete independence. The last group, headed by Carlos Manuel de Céspedes y Borja del Castillo (1819-74), a wealthy planter who proclaimed the revolution at Yara on Oct. 10, 1868, demanded the gradual emancipation of the slaves and universal suffrage.

War was confined almost wholly to the eastern provinces, but Spanish volunteers committed horrible excesses even in Havana. The rebels also burned and killed indiscriminately. Although there was agitation in the U.S. for intervention in the struggle on behalf of the Cubans, the movement was not successful, perhaps because the U.S. had just emerged from a bloody civil war itself and was busy healing its wounds. Thirty years later the U.S. would intervene and obtain the independence of Cuba, but many changes had to take place in the U.S. in the meantime to bring about the necessary shift in public opinion.

War ended in 1878 when Spain by the convention of El Zanjón promised sweeping government reforms, an amnesty to political prisoners, liberty for rebel slaves and the abolition of slavery. Spain gave Cuba direct representation in the *Cortes* and later abolished slavery (gradual abolition in 1880 and definitive abolition in 1886).

But the armistice proved short lived. Spain expected the Cubans to pay for the property damage resulting from the war and soon forgot about political reforms. Royal officials even began to choose members of the provincial assemblies and town councils. With sentiment for independence again sweeping the island, the government began to rule as despotically as before.

Spain's forgotten promises of reform were not the only cause for the war to the death that began in 1895. A severe financial crisis in the United States and the repeal of the tariff act favouring importation of Cuban sugar into the U.S. were bringing widespread unemployment and economic hardship to the Cubans. Sugar plantations were idle, and sugar cane was Cuba's main crop.

When Spain suspended constitutional guarantees in Feb. 1895, the leading chiefs of the Ten Years' War—Máximo Gómez y Báez, Antonio Maceo y Grajales, José Martí, Calixto García, Iníiguez and others—again took to the field. Martí (1853-95), a famous poet who dedicated his life to Cuban independence, unified the movement through the Cuban Revolutionary party founded in the U.S. in 1892. These patriots drew up a constitution for a republic and appointed a governing council headed by Salvador Cisneros y Betancourt.

This war also began in the east but spread rapidly to the western provinces. Spain sent more than 200,000 troops and used the severest measures to crush the rebellion. The rebels retaliated with a scorched-earth policy, burning especially the plantations, on the grounds that Spain would never give up the island unless it was not worth having. The Spanish attempted to isolate their foes with entrenchments, barbed-wire fences, lines of blockhouses across the narrow parts of the island and noncombatant detention camps. The last measure produced much suffering and death among the civilians who were forced into the camps by the thousands. Widespread condemnation of the policy forced Spain to abandon it. A newly appointed liberal premier, Práxedes Mateo Sagasta, abolished the system, recalled the general who had estab-

lished it and promised Cuba an autonomous regime, proclaimed in Oct. 1897. But again final authority rested in the Spanish governor. Moreover, the rebels by then would accept nothing but complete independence, and so the plan was not put to a test.

At this point, Pres. William McKinley asked Spain for permission to mediate the conflict. Spain, although willing to accept some of McKinley's terms, was unwilling to have him serve as arbiter in case peace were not re-established by Oct. 1, 1898. In Feb. 1898 the U.S. battleship "Maine" was blown up in Havana harbour. U.S. public opinion demanded war with Spain.

**4. U.S. Occupation.**—The war, beginning in April, was over in a few months. (See SPANISH-AMERICAN WAR.) A U.S. blockading force destroyed a Spanish squadron seeking to escape from Santiago harbour on July 3, and within two weeks Santiago surrendered after its capture by land forces. Other operations in Cuba were slight. By the treaty of Paris, Dec. 10, 1898, Spain "relinquished" the island to the United States in trust for its inhabitants. The temporary character of U.S. occupation was evident throughout the treaty, in accordance with the terms of the U.S. declaration of war in which the U.S. had disclaimed any intention of controlling the island except for its pacification and had expressed the determination to leave the island thereupon to the control of its people.

Spanish rule ceased on Jan. 1, 1899, and was followed by U.S. military rule from Jan. 1, 1899, to May 20, 1902. During these years the majority of offices were filled by Cubans. Much was done for public works, sanitation, education and public administration. Most notable of all, yellow fever was eradicated where it had been endemic for centuries. A constitutional convention met at Havana from Nov. 5, 1900, to Feb. 21, 1901. The constitution finally adopted contained certain provisions known as the Platt amendment, imposed by the U.S. as a condition for accepting the constitution and approved by Cuba on June 12, 1901. By these provisions Cuba promised not to incur debts its current revenues would not bear; to continue the sanitary administration undertaken by the U.S. military government; to lease naval stations to the U.S.; and, if necessary, to permit the U.S. to intervene in order to preserve Cuban independence and a government adequate to protect life and property. The status of the Isle of Pines was left for future adjustment by treaty, and in March 1925 the U.S. senate by treaty recognized it as a part of Cuba.

**5. The Republic.**—The first Cuban congress met on May 5, 1902, and took over the government from the U.S. military authorities on May 20. Tomás Estrada Palma (1835-1908) became the first president of the new republic. During his administration material prosperity came to Cuba thanks to a reciprocal trade treaty which had been requested earlier by the outgoing U.S. authorities permitting more Cuban sugar to enter the U.S. Sugar again became the basis for Cuban prosperity. A U.S. naval base was established at Guantánamo (q.v.) in 1903.

Palma's administration, although attempting to continue the progressive measures of the U.S. occupation with the surplus in the treasury brought by increased sugar production and the tariff reduction on sugar entering the U.S., was plagued by corruption as well as by the demands of veterans for pensions. Pension frauds and failure to bring about the governmental reforms demanded by the Cubans brought revolution against Palma in July 1906. The revolutionaries, the Liberals, denounced the Moderates in power, accusing them of stealing in the elections of Dec. 1905 and March 1906. Insurrection spread rapidly, and Palma requested intervention by the U.S., which sent commissioners to mediate.

Mediation failed. The president resigned and congress adjourned without naming a successor. As an alternative to anarchy the U.S., on Sept. 29, 1906, proclaimed a provisional government, to last "long enough to restore order and peace and public confidence." Government was maintained under the Cuban flag; the regular constitutional forms remained outwardly unchanged. The insurrectionists promptly disbanded. U.S. administration ceased on Jan. 28, 1909, and the republic was inaugurated a second time, with Gen. José Miguel Gómez (1858-1921) as

president and Alfredo Zayas y Alfonso as vice-president. Both were Liberals. The U.S. troops were withdrawn April 1, 1909.

Three presidents governed Cuba from 1909 to 1925 with little distinction and much corruption. They were Gómez (1909-13), Mario García Menocal (1913-21) and Zayas (1921-25). In this period the U.S. intervened twice in Cuba and threatened to intervene several more times. During Gómez' administration the country prospered, but charges of corruption in the government soon rose, culminating in a bloody race war in 1912 in which thousands lost their lives. The government was accused of giving few offices to Negroes and also of favouring those who had supported the Spanish cause in the war for independence. Zayas and Gómez split and in the election of 1912 the conservative candidate, Menocal, won.

Menocal's administration saw much material progress. With prosperity, however, came new charges of corruption against his government, including that of nepotism. But Menocal won re-election in 1916 by employing fraud and violence. As a result, war broke out against him (Feb. 1917), but he was able to defeat the rebels and enter upon his second term. The rebels hoped for intervention by the U.S., which, however, was too occupied with the European situation. Menocal's government declared war on Germany on April 7, 1917, the day after the U.S. entered the war.

In anticipation of the elections of 1920, Gen. Enoch H. Crowder of the U.S. army was invited in 1919 to draw up a new election law. But the law was flagrantly disregarded in the elections. Menocal now backed Zayas, the Liberal candidate in 1916, in a Conservative-Popular alliance against Gómez, who was nominated by the Liberals. When Zayas was declared elected, Gómez protested. Crowder suggested new elections but while preparations were being made to hold them, Gómez withdrew and Zayas was elected easily.

Until 1919 Cuba enjoyed phenomenal prosperity, thanks to the high price of sugar. By 1920, however, a severe financial crisis had struck the country. Despite a moratorium many banks and other business concerns had gone bankrupt by 1921. At the suggestion of the U.S. government Zayas introduced financial reforms and was given a \$50,000,000 loan by the U.S. (Jan. 1923). The economic situation rapidly improved, the year 1922-23 closing with a surplus. But with the return of prosperity Zayas' administration was accused of corruption, and revolts broke out against him, led in part by war veterans who were not receiving their pensions. When Zayas tried to get himself renominated, he ran into stiff opposition in his own party. He therefore made a pact with the Liberal candidate, Gen. Gerardo Machado y Morales, against Menocal, who ran as the Conservative candidate in the election of 1924. Machado was elected overwhelmingly and assumed office on May 20, 1925. In 1928 he was elected to a second term.

Machado became Cuba's first full-fledged dictator. Pledged to a program of reform, he made good only a few of his promises during his first term. With his second term a rule of terror began. Martial law was proclaimed, and congress allowed him to suspend freedom of speech, press and assembly. Political opposition, allayed by an adroit distribution of patronage in 1928, revived against Machado as the economic depression of the early 1930s hit Cuba. An attempt to stabilize the price of sugar, always the mainstay of Cuba's economy, failed, and no substantial relief came from a public-works program. As the opposition increased, Machado adopted increasingly harsher methods against it. Cuban exiles swarmed to the U.S. Machado's rule seemed fastened on the island for life, since the U.S. did not want to intervene, but when a violent outbreak occurred the U.S. offered to mediate. Its offer was accepted. An amnesty was declared and constitutional and political reforms promised. With the economic crisis deepening and with Machado apparently determined to stay in office in spite of promises to resign, a general strike broke out forcing him to flee the country in Aug. 1933.

Cuba had many presidents in the following years, but they were usually made and unmade by Fulgencio Batista y Zaldívar, a sergeant who gained control of the army at the time of Machado's

downfall. Carlos Manuel de Céspedes y Quesada, son of the 19th-century leader of the Cuban separationists, was the first president serving on a provisional basis. He set aside the constitution and tried to bring about a few reforms. But the university people feared that he was too closely allied to the U.S., and with the rank and file of the army they overthrew him after a few months and put Ramón Grau San Martín in his place. Grau San Martín's attempts at reform were also short lived. His four months in office were characterized by bloody strife. A military junta, headed by Batista, then conferred the office on Col. Carlos Mendieta, who seemed to have the approval of most factions. The U.S. and other countries granted him prompt recognition. Under him a treaty was signed with the United States (June 1934) abrogating the Platt amendment. This famous document, issued to preserve peace, had had the opposite effect, since discontented factions had frequently risen against Cuban governments in order to bring about U.S. intervention. It had also been used by such leaders as Zayas to get the people to support them as champions of Cuban liberty against U.S. aggression.

Disorder and strikes continued, but provisional President Mendieta and his chief of staff, Batista, frankly used dictatorial measures and postponed elections until Dec. 1935. Batista continued to rule Cuba through a succession of presidents (José Barnet y Vinageras, Dec. 1935-May 1936; Miguel Mariano Gómez y Arias May-Dec. 1936; Federico Laredo Bru, Dec. 1936-Oct. 1940).

Finally, in 1940 Batista, then a colonel, presented his own candidacy, defeating Grau San Martín. During his full term, 1940-44, Cuba entered World War II on the side of the Allies and established diplomatic relations with the U.S.S.R. Batista's candidate, Carlos Saladrigas y Zayas, ran in 1944 but was defeated by Grau San Martín and Batista soon left the country. Grau San Martín's administration began with much emphasis on "political house cleaning."

In foreign affairs, Cuba joined the United Nations, and its capital served as the site of the international trade conference of 1947, which produced the Havana charter. In domestic affairs, the administration took an active part in disputes between labour and capital and appeared to lean toward collectivist political and social ideas.

Carlos Prío Socarrás became president in 1948. As a result of violent political agitation and charges of corruption, Batista, who had returned to Cuba, overthrew the government in March 1952 without bloodshed. He closed congress and called for elections in 1954. He was elected president without opposition for a four-year term beginning Feb. 24, 1955. He declared the 1940 constitution, containing many liberal pro-labour reforms, again the law of the land and tried to return the country to normalcy. But strong opposition developed against him. Anti-Batista elements denied the validity of the election and organized a campaign of harassment and sabotage in the provinces. Cuba was in a state of virtual civil war after 1957 as a well-armed force of revolutionaries led by Fidel Castro (q.v.) carried on widespread guerrilla warfare from the mountain fastness of Oriente province.

**6. The Castro Regime.**—Batista resigned and fled the country on Jan. 1, 1959. In a provisional government Castro took the position of premier and designated Manuel Urrutia Lleo president. With opposition to the new government forbidden, trials and executions of Batista followers and other opponents of Castro's government numbered around 700 by early 1961. Many thousands languished in jail, while additional thousands fled the country. Castro resigned as premier July 17, but resumed office after Urrutia resigned as president. Osvaldo Dorticós Torrado was appointed president.

Castro's government soon embarked on a violent propaganda campaign blaming the ills of Cuba on the United States. At the same time warm friendship was expressed for the communist countries and closer economic ties were established with them. In July 1960 the U.S. congress authorized the reallocation to other countries of the Cuban sugar quota. By the end of 1960, U.S. investments in Cuba amounting to approximately \$1,000,000,000 had been seized. Following a continuous campaign of vilification against the U.S. government, including a charge that it planned

an imminent invasion of Cuba and a demand that the staff of the U.S. embassy in Havana be drastically cut, the U.S. government broke diplomatic relations with the Castro government on Jan. 3, 1961. The following month a reorganization of the Cuban government along the lines of the governments of the communist countries centralized even more the means of production of the island in the hands of a few procommunist followers of Castro. The avowed reason for this action was to hasten the industrialization of Cuba. In April 1961, José Miró Cardona, president of the Revolutionary Council of Cuban Refugees, announced that troops were being landed in Cuba to overthrow the Castro regime. The invading force was defeated and forced to surrender. U.S. participation in the organizational phase of the invasion caused serious repercussions throughout the world.

The foreign ministers of the Organization of American States, meeting at Punta del Este, Urug., in Jan. 1962 excluded Cuba "from participation in the inter-American system" because of the Castro regime's adherence to communism. This action was designed to exclude Cuba from O.A.S. activities but not to deprive Cuba of its O.A.S. membership. At the same time the foreign ministers imposed an arms embargo against Cuba.

Evidence that the communist nations were sending military weapons and armed forces to Cuba led to an international crisis in late 1962. On Oct. 22 the U.S. accused the Soviet Union of establishing offensive missile bases in Cuba, declaring that these bases constituted an immediate danger to the western hemisphere. President Kennedy demanded the prompt removal of the missiles and also ordered the U.S. navy to search all ships en route to Cuba and to prevent them from delivering to Cuba additional weapons that could be considered as offensive. In the next few days several ships were stopped but then allowed to proceed when no offensive weapons were found. On Oct. 28 the Soviet Union agreed to the U.S. demand and ordered the dismantling of the missile bases. By mid-November U.S. aerial reconnaissance showed that all such bases had been dismantled, though Cuba continued to maintain an arsenal of communist-supplied defensive weapons. In Dec. 1962 Castro released 1,179 prisoners taken in the invasion of April 1961 in exchange for about \$50,000,000 worth of food and medicine, supplied mostly by U.S. industrial firms.

In July 1964 the foreign ministers of the O.A.S. met in Washington, D.C., at the request of Venezuela, which had discovered that Cuba had been supplying weapons to Venezuelan revolutionary groups. By a vote of 15-4 the ministers approved a resolution condemning Cuba for its actions against Venezuela and also agreed to sever diplomatic relations with Cuba; suspend all trade with it except for foodstuffs, medicines and medical equipment; and cut off all sea transportation to and from the country.

About 500 delegates from more than 80 Asian, African and Latin American countries met in Havana in Jan. 1966 to consider ways of combating imperialism and promoting revolution throughout the world. At the conference the delegates established the Afro-Asian Latin American People's Solidarity organization and appointed a Cuban as its first secretary-general. (F. L. HN.; X.)

## V. POPULATION

After the wars of independence Cuba's population grew rapidly, both from natural increase and from immigration. By 1953, the latest census, the total was 5,829,029, a 20% increase over 1943. A population of about 7,630,700 was estimated for the mid-1960s. The revolution of the late 1950s affected population growth and distribution, but no precise measure of the change is available.

In line with world-wide trends, Cuba's population is steadily becoming more urbanized. In the 1953 census 57% of the people were classed as urban, compared with 51% in 1931. (A slight change in definition of urban in 1953 enlarged the figure for that year but does not alter the trend.) Havana province, with 89% urban, ranks first, and Oriente, with 28%, lowest among the six provinces. The largest cities were Havana, Marianao, Santiago de Cuba, Camagüey and Santa Clara.

The announced birth rate in 1953 of 25.1 per 1,000 and the death rate of 6.5 per 1,000 were both considerably under the true figure. A better indication of the vitality of the population was the ratio

of children under 5 years per 1,000 women 14-49. This ratio by comparison with the United States (which also had a birth rate of 25 per 1,000) was much higher. Oriente province had the highest index of fertility and Havana the lowest. Cuba had nearly 105 males per 100 females. (L. NN.)

## VI. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Government.**—The United States-influenced constitution of 1901 provided for a unitary state with separation of powers and checks and balances. Corruption, inefficiency, ruthless disregard for individual liberty and freedom and irresponsible executive dictatorship characterized one Cuban government after another under this constitution. When the Platt amendment (*see above, History*) was abrogated in 1934, therefore, the Cubans immediately began preparations for governmental change. The constitution of 1935, which never went into effect, largely rejected United States influence. When the constituent assembly met in 1939 to draft a new constitution, practically no one present wanted to continue with separation of powers and presidential government. The constitution of 1940 established a semiparliamentary system. Suffrage was made universal, equal, secret and obligatory for both sexes over 20 years of age; elaborate safeguards against fraud were devised in the electoral code of 1943; parties could be formed by petition of 2% of the voters in the last electoral census; and a system of proportional representation was used for allocating seats in the senate. The two-house legislature was continued. (The size of the senate was increased from 54 to 72 and that of the house of representatives from 130 to 195 in 1956.) The president, elected directly for a four-year term, was made responsible to the legislature by provisions which permitted either house to force his cabinet ministers to appear and be subjected to questioning or interpellation (formal questioning of ministerial policy or actions). If either house should vote lack of confidence, the minister was obligated to resign within 48 hours. The greatest procedural weakness of the new system was the requirement of a majority of the votes of all members of the legislative chamber concerned to initiate interpellation and vote of confidence, instead of a simple majority of the members present, assuming a quorum.

Batista, elected president in 1940, gave the semiparliamentary system his co-operation. He appointed a distinguished man of the highest ability and integrity, Carlos Saladrigas y Zayas, to be his prime minister. The legislature interpellated a number of the cabinet ministers in May 1942. However, the "liberal" Grau San Martín, elected president in 1944, crippled the system and established the pattern that was later followed. The crucial event was the interpellation of Grau San Martín's minister of commerce, Alberto Inocente Alvarez, in the house of representatives in Oct. 1945 for alleged fraud in handling exchanges of Cuban sugar for Argentine fats. The house voted lack of confidence in Alvarez on Oct. 9 by a vote of 79-13. Grau San Martín immediately thwarted the purpose of the semiparliamentary system by appointing Alvarez (Oct. 11) minister of state. On Oct. 20 Prime Minister Prío Socarrás informed the legislature that the president did not feel that he should be bound by majority votes in the legislature. After that the semiparliamentary system was little more than a form. Cuba continued in practice to have strong, centralized, executive government. Batista, who seized power by force on March 10, 1952, governed by decree under a constitutional code of 275 articles until he could win a *candidato único* (single candidate) election on Nov. 1, 1954. With his inauguration on Feb. 24, 1955, the constitution of 1940 was restored. After 1952, however, there were repeated efforts to oust Batista from power by force, and as a result the president governed by *estado de sitio* (state of siege) much of the time.

In addition to the attempt to replace omnipotent executive power by a semiparliamentary system, the constitution of 1940 followed the trend of all recent Central and South American constitutions in providing for the "interventionist" or welfare state. The central government was given great power to direct, regulate and control the economy. Individuals were given practically all the material benefits of welfare and social security that any country in the world made available. Organized labour was protected

by the government. Although Cuba is a rich country and the government collects large sums of money through taxes, the politicians failed to use the public's money to provide more than a small part of the welfare benefits which the constitution theoretically guaranteed. Governments after 1940 were generally "labour" governments, which supported labour's demands for higher wages, fewer hours for the same pay, lower production and price controls. Although some unions undoubtedly derived special benefit from such demands, it was at the expense of lower efficiency and reduced production, which adversely affected material standards of living for the people as a whole.

After Fidel Castro seized power by force on Jan. 1, 1959, he established a political dictatorship. Although Castro had promised that he would hold elections and guarantee constitutional government, it was announced on Jan. 6, 1959, that his administration would rule by decree for at least 18 months, later extended to 4-5 years. In 1960 and 1961 Castro made clear that his government intended to maintain dictatorial power indefinitely. The evidence of dictatorial government was seen in Castro's charismatic leadership; the execution of political enemies after military trials; the provision that civil courts could impose the death sentence and long prison terms for all counterrevolutionary activities with persons so accused refused bail and held incommunicado; the imprisonment of many thousands of Cubans; the elimination of all political parties except the communist (called the Popular Socialist party); the abolition of all press opposition (by Jan.-Feb. 1960); the establishment of centralized government control of all media of communication; the increasingly vitriolic attacks on the Roman Catholic Church; and the repudiation of friendship with the United States in favour of ties with the Soviet Union, Communist China, Czechoslovakia and other communist satellites. The Castro-appointed president and council of ministers enacted a fundamental law on Feb. 7, 1959, under which the council was given authority to represent the sovereign power of the state. In theory the council could govern by decree in any field whatever, unrestricted by constitution, law or courts. In fact, however, the council of ministers did not formulate important policy. That was done by Castro himself; by his brother Raúl, chief of the armed forces; Ernesto ("Che") Guevara, head of the National bank and a communist since his university days in Buenos Aires; Osvaldo Dorticós Torrado, president and long-time communist; and Antonio Núñez Jiménez of the National Agrarian Reform institute (INRA), also a long-time communist. In a speech on May 1, 1961, Castro proclaimed the official establishment of Cuba as a socialist state. In Dec. 1961 Castro announced in another speech that he had been a convinced Marxist-Leninist since his student days but had concealed the fact until he could gain power. In 1962, Castro began the organization of a single all-powerful party (the United Party of the Socialist Revolution), which would perform a role similar to that of the party in other Communist countries.

Prior to the Castro regime justice was administered through the Roman law system of codes, most of which were either copies of Spanish or other Central and South American codes or were influenced strongly by such sources. The court system was highly centralized and included the usual categories of special courts, courts of original jurisdiction and appellate jurisdiction and a supreme court. Cuba copied Colombia's system under which any person could challenge the constitutionality of any law or decree by presenting a petition of unconstitutionality directly to the supreme court. This principle, which is somewhat similar to judicial review, acted as a check on executive and legislative power in Colombia, where about 50 important laws were declared unconstitutional. It never acted as a check on the powerful executive in Cuba, however. Under the Castro government most judicial functions were handled by revolutionary tribunals which had practically summary jurisdiction.

Cuba being a highly centralized state, the central government naturally spends most of the revenues derived from taxation, appoints most governmental personnel, formulates important policy and administers the major functions of government. The central government definitely overshadows the local and provincial gov-

ernments. After 1940 the municipalities were able to have a form of local charter. They had the mayor-council system and elected their own officials, who could not legally be removed by the provincial or central authorities. The voters elected a governor for each of the six provinces, and the *alcaldes* (mayors) of the cities and towns made up provincial councils. Even the officials of the capital city of Havana were elected locally, in contrast to the usual practice in Central and South America. The mayor of Havana was considered second in importance politically only to the president of the country. In the Castro revolutionary government, however, power was highly centralized in the revolutionary group and even the president became a figurehead, with the real authority embodied in Castro.

**2. Education, Health and Social Welfare.**—Cuba undoubtedly has had one of the most distinguished records of any of the Central and South American countries in education, health and social welfare. In part, this has derived from the fact that the government, particularly at mid-20th century, has had a relatively large amount of money to spend. In addition, education has high prestige value in Cuba, and all levels of government are dedicated to improving and expanding it. The law states that education is compulsory and free for all children from 7 to 14 years of age. Usually more than 22% of the budget of the central government is allotted to education, and many schools have been constructed and teachers hired. Official statistics claim that only about 22% of the population over 15 is illiterate. Since 1959 the government of Fidel Castro has claimed virtually to have eliminated illiteracy in Cuba. The population of the urban centres is growing, on an average, about twice as fast as the rural population, and among the Central and South American countries only Uruguay, Argentina and Chile are more urbanized than Cuba. This has sometimes been cited as justification for using most of the education budget for the construction of new schools and facilities in the cities rather than in the country. When politicians permitted rural schools to be constructed, they frequently had them built, it has been said, near the public highways to impress voters, rather than in the interior where the rural children could more easily reach them. The University of Havana is the largest of four universities. Both students and faculty are active in politics and use or permit the use of armed violence. As a result, the universities have been shut down by order of the government from time to time. Health facilities are unusually good in the urban centres of Cuba in comparison with other Central and South American countries. The U.S. occupation is credited with initiating such measures as water purification and sanitation. In the rural areas the water is likely to be contaminated, and the people suffer from amoebic dysentery and other intestinal disorders. Cuba has a network of hospitals, clinics and other services which provide subsidized care (W. S. Ss.)

## VII. THE ECONOMY

**1. Production.**—The economy of Cuba since 1900 has been based primarily on the growing and grinding of sugar cane, although efforts toward economic diversification have been undertaken. Sugar is grown throughout the country, but the heaviest concentrations are in the eastern half of the island in Oriente and Camagüey provinces. Sugar cane is ground into raw (brown) sugar in about 160 sugar mills (called *centrales*), and blackstrap molasses is produced as a by-product. Very little sugar refining, however, occurs in Cuba. The production pattern became uncertain, or at least harder for an outsider to evaluate, after the advent of the Castro regime in 1959. In 1960 sugar imports from Cuba were embargoed by the United States.

The modern sugar era began in Cuba about 1900 and was facilitated by major expansion of the United States market. Subsequently the industry became the victim of violent price fluctuations. Extremely prosperous 1920, called the year of "the dance of the millions," was followed by a disastrous price slump in 1921 and the pattern has been repeated many times. In consequence the sugar industry has always been subject to extensive regulation. After the establishment of the Castro regime, much of the agricultural land was expropriated (if not confiscated) and a major

effort was made to establish an extensive system of agricultural co-operatives. The responsible agency was the INRA.

Other agricultural activities consist of livestock raising and the growing of tobacco, food crops and fruits, such as bananas, pineapples and papayas. Cuban tobacco, which is widely used in cigars, is grown chiefly in Pinar del Río, in the west. The only fibre commercially produced in Cuba has been henequen. The production of ambary (*kenaf*), another fibre, was in the experimental stage in the mid-1960s. Direct investment by the United States in the agricultural sector of the Cuban economy declined considerably from a peak of 575,000,000 pesos in the 1920s to an estimated book value of 276,000,000 pesos at the end of 1955, and in 1959-60 nearly all U.S. holdings in Cuban agriculture were confiscated by the Castro government.

Cuba was once an important producer of hardwoods. By the second half of the 20th century, however, the principal woods formerly exported, mahogany, Spanish cedar and sabicu, were under export embargo.

Cuba has a fairly important mining industry. There is a large copper deposit in Pinar del Río, at Matahambre. Large deposits of low-grade iron ore (especially laterite) exist, principally in Oriente province; however, they have not been extensively developed. There is also nickel in the Moa bay region. Much of the mining industry was nationalized by the Castro government.

Cuba's considerable fishing resources have not been extensively developed. The annual catch averages between 50,000,000 and 60,000,000 lb.—not enough to fill all the country's consumption requirements. The principal varieties caught are grouper, snapper, yellowtail, mackerel, muttonfish and sardines. Sponge fishing, once an important export industry, was in decline in the second half of the 20th century partly because of the sponge blight, which became endemic in the Cuban beds around 1939, but also because of competition from synthetic sponges and overexploitation.

Cuba has no coal. Hydroelectric potential is negligible, and known petroleum reserves are also insignificant. The chief household fuel is charcoal, which is obtained from local firewood. A sugar cane by-product called bagasse supplies much of the fuel used in the sugar industry.

The manufacture of raw sugar cane from cane is the principal industry in Cuba. Associated with the sugar industry is the manufacture of rum and of industrial alcohol from blackstrap molasses. Cuba had no heavy industry in the middle part of the 20th century. Other industrial activity included the production of tobacco products, foodstuffs, beverages and light consumer goods for domestic consumption. The government has engaged in considerable planning designed to encourage industrialization.

**2. Trade and Finance.**—Havana, the capital, is by far the most important as well as the largest commercial centre in Cuba. Nearly all the island's banks and insurance companies, sugar mills, manufacturing enterprises and wholesale distributing firms have their main offices there.

Sugar accounted each year for more than 80% of Cuba's total exports before the United States in 1960 banned further importation of sugar from Cuba. The Soviet Union became relatively much more important in the Cuban trade picture and the United States much less. As a consequence of devoting so much effort to the production of sugar and tobacco for export, Cuba has normally been dependent on imports to meet much of its food requirements. The chief imports of this type have been land, rice, wheat and flour, dairy products, beans and potatoes. Petroleum products and automobiles have also been imported. In Oct. 1960 the United States announced an embargo on all exports to Cuba except medicines, medical supplies and certain foods.

The peso of 100 centavos is the country's monetary unit. On the foreign exchange market one Cuban peso in 1960 was equal in value to one U.S. dollar, but exchange control was vigorous. The National bank of Cuba carried out the functions of a central bank. It was the sole bank of issue and fiscal agent of the government.

**3. Transport and Communications.**—In the mid-1960s Cuba had a total of 5,000 mi. of all-weather roads and 3,200 mi. of other roads. The backbone of the highway network was the Central highway, which extended from Pinar del Río to Santiago, a

total of 710 mi. The railroad network had a total of 11,250 mi. of track well distributed throughout the island. Most of the public utilities were nationalized by the Castro government.

**CUBE**, a regular solid with six square faces; that is, a regular hexahedron (see SOLIDS, GEOMETRIC). Since the volume of a cube is expressed, in terms of an edge  $e$ , as  $e^3$ , in arithmetic and algebra the third power of a quantity is called the cube of that quantity. That is,  $3^3$ , or 27, is the cube of 3; and  $x^3$  is the cube of  $x$ . A number of which a given number is the cube is called the cube root of the latter number (see ROOT); that is, since 27 is the cube of 3, 3 is the cube root of 27—symbolically,  $3 = \sqrt[3]{27}$ . A number that is not a cube is also said to have a cube root, the value being expressed approximately; that is, 4 is not a cube, but the cube root of 4 is expressed as  $\sqrt[3]{4}$ , the approximate value being 1.587, because  $1.587^3$  is approximately 4.

In Greek geometry the duplication of the cube was one of the most famous of the unsolved problems. It required the construction of a cube that should have twice the volume of a given cube. This has been proved to be impossible by the aid of the straight edge and compasses alone, but the Greeks were able to effect the

construction by the use of higher curves, notably by the cissoid of Diocles (see CURVES, SPECIAL). Hippocrates showed that the problem reduced to that of finding two mean proportionals between a line segment and its double; that is algebraically, to that of finding  $x$  and  $y$  in the proportion  $a:x = x:y = y:2a$ , from which  $x^3 = 2a^3$ , and hence the cube with  $x$  as an edge has twice the volume of one with  $a$  as an edge.

**CUBEB** (CUBEB BERRIES), the dried, unripe fruit of *Piper cubeba* (family Piperaceae), a perennial vine native to Java, Sumatra and Borneo and cultivated in Java, Sumatra, Ceylon and the West Indies. Most of the commercial supply is shipped from Jakarta and Singapore. The fruits are gathered while still unripe but fully grown, and carefully dried in the sun. Their odour is agreeable and aromatic, their taste pungent, acrid, slightly bitter and persistent. Cubeb contains about 15% of a volatile oil from which a solid known as cubeb camphor can be separated. The drug was known by Arab physicians in the 9th and 10th centuries. It was used in Europe as a spice from the 11th century and medicinally as a diuretic from the beginning of the 19th century. The berries were also crushed and smoked in cigarettes for catarrh and asthma. Since its beneficial effect is too uncertain to offset undesirable side effects, it has been replaced by more reliable remedies. (V. E.)

**CUBE ROOT:** see ROOT.

**CUBISM**, a revolutionary phase of the modern art movement, developed in Paris during 1907–14. The name was a scornful description by a critical public. The movement unfolded as a corollary to Fauvism (*q.v.*), to the current enthusiasm for primitive art in general and African Negro sculpture in particular and to the deep impression caused by the Paul Cézanne retrospective exhibition at the 1907 Salon d'Automne.

The most immediate of these influences was a keenly appreciative realization of Cézanne's conception of painting as "a construction after nature." This theory, exemplified by his work, was confirmed by his saying that nature should be treated in terms of the cylinder, cone and sphere. For Cézanne, the end was the discovery of a significant equivalent for the object. For the Cubists the object was the starting point: from it they abstracted elements and created compositions of imagined rather than observed forms and relationships. Cubism progressed through three phases. The first, the Cézanne phase (1907–09), was a period of assimilation and modification of Cézanne's methods and theory. The second, the analytic (1910–12), was characterized by nearly monochromatic colour, a complex fragmentation of form and the use of simultaneity (representation of several aspects of the same object). In the third, called synthetic (1912–14), colour reappeared and textural surfaces were applied in a technique of collage (the sticking of extraneous material onto the canvas).

In 1908 the Bateau-Lavoir studios in Montmartre became the rendezvous of Cubists and their supporters. Outstanding in the group were Pablo Picasso (whose "Les Femmes d'Alger" of 1906–07, is regarded as the first identifiable Cubist picture), Georges Braque, André Derain, Juan Gris, Louis Marcoussis and Jean Metzinger. Other artists linked with the movement were Robert Delaunay, Albert Gleizes, Edouard Jeanneret (Le Corbusier), Fernand Léger, André Lhote, Marcel Duchamp and Jacques Villon. Though the Cubists were dispersed by the outbreak of World War I, the influence of the movement remained and was clearly discernible in the subsequent emergence of abstract painting (see ABSTRACT ART). See also PAINTING: Modern Painting: Cubism.

**CUCKOO**, any member of the cuckoo family, Cuculidae, which comprises about 127 species of small- to moderate-sized birds (6 to 27 in. long). Superficially they could pass for perching birds (order Passeriformes) except for the arrangement of the toes: two toes are directed forward and two backward. Their internal anatomy indicates that the cuckoos and a few close relatives constitute the order Cuculiformes. The Cuculidae are of nearly

world-wide distribution, with most of the species occurring in the tropics; species of the temperate zones migrate to the tropics for the winter. Although without great variation in form, some cuckoos are long-winged tree birds, others are short-winged birds of the shrubbery and ground. The bill varies from moderately stout to very stout, and the pattern and colour of the plumage is very variable. Perhaps the point of greatest interest in the group is the wide variety in their nesting habits, though the young are all hatched in a helpless condition and must be cared for in the nest. The European cuckoo, *Cuculus canorus*, has long been noted for its habit of laying eggs in the nests of other kinds of birds (a condition called social parasitism).

In America the two common tree cuckoos are the black-billed cuckoo (*Coccyzus erythrophthalmus*) and the yellow-billed cuckoo (*C. americanus americanus*). They are similar in appearance, each being about a foot long, slender, long-tailed, olive-brown above and white below; the latter, however, has yellow in the bill, rust in the wing, and broad, rather than narrow, white tips to the tail feathers. Both are similar in habits. They usually stay well hidden among the leaves of trees and shrubs, make rather deliberate movements and seek out caterpillars as their favourite food. Their calls are a series of notes often written "cow-cow . . ." but having considerable variation. Usually these birds build their own nest, a scanty platform of twigs lined with soft material. Two to four greenish-blue eggs are laid in the nest and incubated by the parent. The young, naked at hatching, soon become covered with immature plumage that is very much like that of the adult. Only occasionally does the yellow-billed cuckoo lay its eggs in the nests of other birds and leave its offspring to be raised by foster parents. In winter both species migrate to the American tropics.

The common or European cuckoo, with a wide range in Europe and Asia, migrates as far as South Africa in winter. It is about 13 in. long, with a blue-gray back and breast and barred underparts. It is a tree bird that feeds chiefly on insects. Its call, a loud "coc-coo," has given the name to the family. The bird itself has been used by poets as a herald of summer, and its call, of course, has been widely imitated in cuckoo clocks.

The most interesting thing about this bird is the adaptation for laying the eggs in the nests of other birds and leaving the offspring to be raised by the foster parents. Each female of *Cuculus* confines itself to a small area and specializes in a particular species of foster parent. Included among the 50 species of birds recorded as serving as foster parents to cuckoo young are such species as meadow pipits (*Anthus*) and sedge warbler (*Acrocephalus*). The cuckoo lays about 12 eggs, usually one to each nest. The eggs of each *Cuculus* female tend to resemble those of the chosen foster parent, an adaptation that results in great variation in egg colour within the species. The female cuckoo watches the host species build the nest and begins laying at the same general period that the foster parent does. While the host is away from the nest, the cuckoo removes one of the host's eggs and replaces it with one of its own. Contrary to much early speculation, the egg is laid directly in the chosen nest.

The young cuckoo hatches quickly, in about 12 days. It is entirely naked at this stage. Soon it disposes of its nest mates—the foster parents' eggs or newly hatched young—by getting them on its back and pushing them over the edge of the nest. Thus the young cuckoo receives all the food and care of the foster parents and is ready to leave the nest in about three weeks. It is then in immature plumage, barred above and below. A further interesting point is that the cuckoo's behaviour traits, voice and species recognition are evidently in-born, not influenced by its early

JOHN MARKHAM  
HEDGE SPARROW (*PRUNELLA MODULARIS*) FEEDING YOUNG CUCKOO (*CUCULUS CANORUS*)

environment, except perhaps the recognition of its special foster parents.

The road runner, *Geococcyx californianus*, is a ground cuckoo of the arid parts of western North America. It is a long-tailed, short-winged running bird about 2 ft. long, found in open brush and cactus country. In colour its upper parts are streaked in browns, grays and black and an area of bare skin behind the eye is marked with red and blue. The road runner feeds largely on insects but also takes lizards, small snakes and mice. It makes a rather bulky nest in shrubbery and lays up to five white eggs. Since the young hatch a few days apart, a nest may have various sized young in it.

In the American tropics are several species of black cuckoos called anis, such as the smooth-billed ani (*Crotophaga ani*), about 13 in. long, with a long tail and a deep, curved bill. They spend much time in the shrubbery and feed on the ground. Their nesting is peculiar in that several females may lay eggs in one nest and may share incubation duties and care of the young. See also BIRD.

See H. Friedmann, "Social Parasitism in Birds," *Smithsonian Institution Report for 1929*, pp. 363-382 (1930); E. C. Stuart Baker, *Cuckoo Problems* (1942). (A. L. Rb.)

**CUCKOOPINT**, called also lords-and-ladies (*Arum maculatum*), is a tuberous herb of the arum family (Araceae) native to southern Europe and northern Africa. Like many other aroids, cuckoopint contains a bitter, sometimes poisonous sap; the red berries, however, are particularly toxic. In England, where it is common in woods and hedgerows, it is also called wake-robin. It grows from a whitish rootstock, which sends up in the spring a few long-stalked, arrow-shaped, polished green leaves, often marked with dark blotches. These are followed by the fleshy spadix bearing in the lower part numerous tiny flowers and continued above into a purplish or yellowish appendage; the spadix is enveloped by a whitish or purplish leafy spathe, 6-10 in. long, constricted in the middle to form the flower chamber. Insects visit the plant, attracted by the fetid smell, and carry the pollen from one spathe to another. As the fruit ripens the spathe withers, and the brilliant red poisonous berries are exposed. Its counterpart in eastern North America is the jack-in-the-pulpit. See ARACEAE; ARUM; JACK-IN-THE-PULPIT.

**CUCKOO SPIT INSECT**, any insect of the family Cercopidae (order Homoptera) whose immature stages produce a frothy, whitish secretion found upon stems of various plants. They are also known as froghoppers or spittle bugs. The adult, a grayish-brown winged form with variegated markings, is a powerful leaper. The origin and formation of the froth has been much discussed. It appears that juices of the plant imbibed by the whitish nymph, when voided from the alimentary canal, become mixed with the secretion of special abdominal glands, which enables the product to maintain its foamy coherence and hold the air bubbles which are introduced through a special valve on the underside of the abdomen. Cuckoo spit is believed to protect the insects from the attacks of enemies and also from desiccation.

More than 2,000 species of this family have been described from various parts of the world. The common cuckoo spit insect of Europe is *Cercopis spumaria*, which also occurs in North America. Most of these insects are small, but in the tropical regions some are of medium size; in Africa certain species occur in enormous numbers and secrete large amounts of honey dew, which drips from the branches like rain. Such trees are called rain trees. One species, the sugar cane froghopper, *Tomaspis saccharina*, is very destructive to sugar cane in Trinidad. Another

species, *Aphrophora salicis*, has been imported from Europe to North America and is sometimes a serious pest of basket and ornamental willow. In Africa, India, the east Indian islands and Australia there is a group of froghoppers which secrete small calcareous tubes of various shapes. The nymphs live inside these tubes in a mass of spittle. The tubes resemble small snail shells and curiously enough were described as species of snails by some of the earlier zoologists. (Z. P. M.)

**CUCULIDAE**, a family of birds, world-wide in distribution, that includes the cuckoos, road runners and anis. See Cuckoo; ROAD RUNNER.

**CUCUMBER** (*Cucumis sativus*), a creeping plant of the family Cucurbitaceae (q.v.) widely cultivated for its fruit, and originated probably in northern India. It is a tender annual with a rough, succulent trailing stem and stalked hairy leaves with three to five pointed lobes; the stem bears branched tendrils by which the plant can be trained to supports. The short-stalked, yellow, bell-shaped flowers are unisexual, but staminate and pistillate ones are borne on the same plant; the latter are recognized by the swollen warty green ovary (the potential cucumber) below the rest of the flower. Flowers are insect pollinated. Hives of bees are commonly placed near plantings in frames or fields or inside greenhouses to ensure pollination and fruit setting.

In the U.S. cucumbers are widely grown as field crops and are extensively grown in home gardens. They are planted in "hills" about 5 by 5 ft. apart, with two plants per hill; or with the plants spaced singly about 2 ft. apart in rows 5 ft. apart. An excess of seed, about 2 to 3 lb. per acre, is sown, and the small plants are thinned to the number desired. In Great Britain and northern Europe the cucumber is extensively grown in frames or on trellises in greenhouses because the climate is so cool that few varieties are productive outdoors.

The heat requirement of the cucumber is one of the highest among the common vegetables. There are three groups of varieties, based on adaptability and use: (1) very large-fruited, strong-growing varieties adapted only to greenhouse or frame culture. Several English greenhouse varieties will form fruits without pollination and seed formation, and are generally much larger than those popular in the U.S.; (2) large-fruited, outdoor-grown varieties for slicing and pickling, and generally having white spines; (3) small-fruited prolific varieties grown outdoors principally for making pickles, and having black spines.

The food value of the cucumber is low but it is popular for salads and relishes. The Sikkim cucumber, *C. sativas* var. *sikkimensis*, is a large-fruited form, reaching 15 in. long by 6 in. thick, grown in the Himalayas of Sikkim and Nepal. The west India gherkin, *Cucumis anguria*, has small, slender vines, and abundant small ellipsoid green fruit covered with warts and spines. It is used for pickling. (V. R. B.; X.)

**CUCUMBER TREE**, the common name for *Magnolia acuminata*, a handsome ornamental tree that reaches a height of nearly 100 ft., bearing large, not very showy, greenish-yellow flowers and three- to four-inch fruits, which, when immature, resemble a small cucumber, but which ripen to a pink or red colour. Another species, *M. macrophylla*, a spreading shrub or small tree, is known as the large-leaved cucumber tree. Both are native to the southeastern United States. See MAGNOLIA.

**CUCURBITACEAE**, the gourd family of prostrate or climbing, generally annual, herbs, usually bearing tendrils and having a rapid growth. The group includes such economically important members as pumpkin, cucumber, watermelon, squash and gourd (qq.v.). This group of dicotyledonous plants contains about 100 genera and about 850 species, found in the temperate and warmer parts of the earth but especially developed in the tropics.

The long-stalked leaves are arranged alternately and are generally palmately lobed and veined. The flowers are borne in the leaf axils, in which a vegetative bud is also found, and at the side of the leaf stalk is a simple or branched tendril. There has been much difference of opinion as to what plant member or members the tendril represents; the most generally accepted view regards the tendril as a shoot, the lower portion representing the stem, the upper twining portion a leaf. The flowers are unisexual,

EDWIN WAT TEALE  
FROGHOPPER (CERCOPIS) NYMPH  
PRODUCING CUCKOO SPIT, A BUBBLE  
SECRETION

FIG. 1.—BRYONY (*BRYONIA DIOICA*)

completely fills the seed.

In North America the family is represented by a few genera comprising about 40 species, which occur chiefly in the southern parts of the United States and Mexico. Among these are the climbing wild cucumber or balsam apple (*Echinocystis lobata*) and the star cucumber (*Sicyos angulatus*), of the eastern United States and Canada; the calabazilla or mock orange (*Cucurbita foetidissima*), of the southwestern U.S. and Mexico; and the manroot (*Echinocystis fabacea*), of California. The family is represented in Britain by bryony (*q.v.*; *Bryonia dioica*) (fig. 1), a hedge climber, perennial by means of large fleshy tubers that send up each year a number of slender angular stems. The leaves are heart-shaped with wavy margined lobes. The flowers are greenish,  $\frac{1}{2}$  to  $\frac{3}{4}$  in. in diameter; the fruit, a red several-seeded berry, is about  $\frac{1}{2}$  in. in diameter.

Among the genera of economic importance are: *Cucumis* (cucumber and muskmelon); *Cucurbita* (pumpkin, squash and marrow); *Citrullus vulgaris* (watermelon), and *C. colocynthis* (colocynth). Other edible cucurbits include: *Ecballium elatarium* (squirting cucumber), which ejects its seeds with a watery fluid by the contraction of the wall of the fruit; *Sechium edule* (chocho), a tropical American species, cultivated for its fruit; it contains one large seed which germinates *in situ*. The fruits of the gourd (*Lagenaria* and others) are often used as ornaments. The fruits of *Luffa cylindrica* have closely netted vascular bundles in the pericarp, forming a loose felt which supplies the loofah or bath sponge; its fruits are edible when not fully mature.

FIG. 2.—FRUIT OF CHOCHO OR CHAYOTE (*SECHIUM EDULE*)

**CÚCUTA**, a city of Colombia, capital of the department of Norte de Santander, adjacent to the Venezuelan border, is the gateway to Venezuela, with highway, rail, river and air connections with that country. Pop. (1961 est.) 142,230. Founded as San José de Guasimal in 1733, it became San José de Cúcuta in 1793. In 1875 Cúcuta was destroyed by an earthquake. A beautiful city and an important commercial centre emerged from the ruins. Nucleus of a livestock and agricultural zone, it has many small industries, and there are oil fields to the north. (T. E. N.)

**CUDDALORE**, a town in Madras state, India, headquarters of South Arcot district, is 15 mi. S. of Pondicherry. Pop. (1951) 68,456; (1959 est.) 85,843. It has two stations on the Southern railway. The town's name comes from the Tamil *kudalur*, meaning "river confluence" (of the Ponnaiyar, which reaches the sea there, and the Gadilam).

Cuddalore consists of two areas: Cuddalore New Town, with district offices and officials' residences, the ruined Ft. St. David and an ancient Hindu Siva temple; and the "old town," the market and port area, to the south. Cuddalore is a roadstead and creek port, with peanuts as the main export. Industry includes peanut-oil pressing and the weaving of coloured cloths and fabrics of silk mixed with cotton, mainly exported to Malaya. There is a large French Roman Catholic mission with a big school.

The British East India company established its Cuddalore factory in 1683. Trade increased rapidly, the warehouses were enlarged and Ft. St. David was built (rebuilt 1720). Robert Clive (*q.v.*) became governor of Cuddalore in 1756. The French took it in 1758, abandoned it in 1760, retook it in 1782 and held it till 1785 when it reverted to the British under the peace treaty. The old governor's garden house is the district collector's residence.

(G. KN.)

**CUDDAPAH (KADAPA)**, a town in Andhra Pradesh, India, headquarters of Cuddapah district, is on the Southern railway 161 mi. N.W. of Madras. Pop. (1951) 37,438. In Telugu *kadapa* means "gate," and the town is the gateway from the north to the sacred shrine of Tirupathi (*q.v.*). Cuddapah lies 5 mi. S. of the Penner river and is shut in on the north, east and south by the rocky Nallamalai and Palkonda hills, rising to 3,000 ft. The heat radiated from these in summer makes Cuddapah perhaps the most uncomfortable town in the region. It has a government arts college affiliated to Sri Venkateswara university at Tirupathi.

CUDDAPAH DISTRICT is well known for its fine-grained compact limestones, used mainly as floor tiles and sometimes as table tops under the name Cuddapah slabs. The Penner and its tributaries are nonperennial. They are torrents after rain, then dwindle to thin trickles in wide sandy beds. Pop. (1961) 1,342,140. Area 5,924 sq.mi.

(G. KN.)

**CUDWORTH, RALPH** (1617–1688), the leading systematic philosopher among the Cambridge Platonists (*q.v.*), was born at Aller, Somerset, the son of Ralph Cudworth (d. 1624), rector of Aller, formerly fellow of Emmanuel college, Cambridge. Cudworth was sent to his father's college and was elected fellow in 1639. In 1642 he published *A Discourse Concerning the True Notion of the Lord's Supper* and a tract entitled *The Union of Christ and the Church*.

At first under a cloud because of his notorious sympathy with nonconformity, he was in 1645 appointed by the parliamentary visitors to the mastership of Clare hall and elected regius professor of Hebrew. He supported the Commonwealth as the only hope of wider toleration; however, in an eloquent sermon to the house of commons on March 31, 1647, he spoke out against the increasing rigidity of the Puritan sectaries. In 1654 he was elected master of Christ's college, whereupon he married. The Restoration, which Cudworth welcomed, left him undisturbed in his mastership of Christ's college, where he died on June 26, 1688. His daughter, Damaris, Lady Masham (1658–1708), friend and correspondent of Locke and of the 3rd earl of Shaftesbury, published in 1696 a *Discourse Concerning the Love of God*; she did much to spread her father's moral and religious ideals.

In 1678 (though the imprimatur was dated 1671) Cudworth published *The True Intellectual System of the Universe: the First Part: wherein all the reason and philosophy of atheism is confuted and its impossibility demonstrated*. A remarkably candid work ("He has raised," Dryden wrote, "such strong objections against the being of a God and Providence that many think he has not answered them"), it aroused considerable theological opposition. He did not publish the second or the third parts. *Of Moral Good and Evil* and *Of Liberty and Necessity*; only fragments remain in manuscript in the British museum. He wrote a short summary of part ii with the title *A Treatise Concerning Eternal and Imutable Morality* (published 1731). *A Treatise of Freewill* (pub-

ished 1838) is probably a summary of part iii.

*The True Intellectual System* is a criticism of two forms of materialistic atheism: the atomic (Democritus and Hobbes); and the hylozoic (Strato and Spinoza), which holds that matter has its own life. Cudworth accepts the atomic theory because, he argues, it shows that matter is entirely inert and so cannot think or be alive. For the Cartesian dualism of extension and thought he substitutes a dualism of matter and life; life may be either conscious (spirit) or that sort of unconscious "plastic power" exemplified in purposeful but unconscious animal instincts. His theory of plastic powers was widely influential, but his metaphysics suffers from being embedded in lengthy historical digressions.

*A Treatise Concerning Eternal and Immutable Morality* is directed against the Calvinists, against Descartes' conception of divine omnipotence and against Hobbes' reduction of morality to civil obedience. It is not an ethics but an attempt to state the philosophical presuppositions of ethics. The mind in knowledge, Cudworth argues, is directed toward "general notions," understood as systems of relationships; these, not the isolated objects of sensation, constitute reality. Such general notions, of which good is an example, are modifications of that divine wisdom in which, as rational beings, we participate. "Things are what they are," he wrote, "not by Will but by Nature." No will, then, whether the Calvinist-Cartesian God or Hobbes's sovereign, can make anything good or evil which is not so by nature. Cudworth's manuscripts sketch a more detailed ethics in which he emphasizes the rational, spontaneous, disinterested, public-spirited character of the good life.

**BIBLIOGRAPHY.**—John Harrison's edition of *The True Intellectual System*, 3 vol. (1845), includes an Eng. trans. of J. L. von Mosheim's notes from his Latin edition (1733), together with the *Treatise on Eternal and Immutable Morality*; Thomas Birch's edition (1743; reprinted 1820) contains Birch's life—the main biographical source—as well as Cudworth's principal sermons and his *Discourse Concerning the True Notion of the Lord's Supper*. As well as the general works listed under CAMBRIDGE PLATONISTS (especially Muirhead), see J. A. Passmore, *Ralph Cudworth* (1951), with extensive bibliography; C. E. Raven, *Natural Religion and Christian Theology* (1953). For Damaris Cudworth see F. A. Keynes, *By-ways of Cambridge History* (1947). (J.N. A. P.)

**CUENCA**, a central Spanish province with a capital of the same name, is situated in the southern half of the Meseta and forms part of the ancient kingdom of New Castile. Pop. (1960 est.) 337,999. Area 6,587 sq.mi. The density of population is very low because of the large area of mountainous and uncultivated land. In the northeast is the Serranía de Cuenca, consisting of a series of plateaus divided by valleys and ravines which give it a complicated topography. The rivers draining this area (the Júcar, Guadiela and Tagus) run through deep valleys in an eroded limestone zone which is as picturesque as the so-called Ciudad Encantada ("Enchanted City") formation nearer Cuenca. The Serranía de Cuenca is a region of pine forests and nomadic pastures. In the north is part of the Alcarria, while westward lie the Sierra de Altamira and broken country, sloping in the southwest to plains which form part of the district known as La Mancha. The climate is bleak and cold in the mountains and extreme on the plains, where summer heat is excessive. Prolonged droughts are common. Cereals, vines and olives predominate in the province, but the main natural source of wealth is timber, used for casks, carpentry and constructional work. The province is crossed by the Madrid-Cuenca-Valencia railway line and there are main roads from Madrid to Valencia and Cartagena.

CUENCA, the capital, 201 km. (125 mi.) E.S.E. of Madrid by rail, lies on the western edge of the Serranía de Cuenca at the confluence of the Júcar and Huécar, whose deep gorges almost surround it. Pop. (1960 est.) 24,969 mun. The Moors built a fortress on the high part. It was finally captured from the Moors in 1177 by Alfonso VIII of Castile, who made it an episcopal see in 1182. It enjoyed great prosperity during the later middle ages and especially during the 16th century, and was well known for its silver and its woolen textiles. Many of its convents and churches and the Romanesque-Gothic cathedral, celebrated for its sculpturing and for its beautifully carved wooden doorway, date from this period of prosperity. Cuenca was partially destroyed

by Napoleonic troops, and later by Carlist rebels in 1874. During the 19th century the town spread to nearby lowland, so that there are in fact two cities: the upper or old city and the lower or modern one. Viewed from below, the houses of the old city, built on a limestone height, appear to be suspended. Formerly walled, old Cuenca still preserves some of its gateways. The streets are very steep, and there are many large houses and palaces. Cuenca's chief trade is in timber from the forests. Its industries are furniture, pottery, paper and leather manufacturing. (M. B. F.)

**CUENCA**, the third city of Ecuador, and capital of the province of Azuay. Pop. (1959 est.) 66,800. It is located in the basin of Cuenca, about 190 mi. south of Quito, and 75 mi. southeast of Guayaquil, at an elevation of 8,468 ft. Cuenca is reached from both Quito and Guayaquil by all-weather automobile highways and by regular airlines. A railroad connects it with the Guayaquil-Quito railroad. The city is the commercial centre for a large part of southern Ecuador, trading in agricultural products, cattle, hides and marble. Its chief manufactured products are Panama hats, made from straw sent up from the coastal lowlands for weaving. Other industries include cotton and woolen textiles, lace, leather, articles of gold and silver, cheese, flour, refined sugar, beer, alcohol and soft drinks. It was founded by the Spaniards in 1557 on the site of an Inca settlement called Tumibamba. In 1786 it was made an episcopal see. It has a fine cathedral, a university and some fine examples of colonial architecture. At its weekly fair people from the surrounding countryside come to buy and sell, and to enjoy the social life. (P. E. J.)

**CUESTA**, a name of Spanish origin for a type of geological structure and land form characterized by a steep cliff or escarpment on one side and a gentle dip or back slope on the other. It occurs in areas of tilted strata and is caused by the differential weathering and erosion of the hard capping layer and the soft underlying cliff maker, which erodes more rapidly.

Cuesta escarpments tend to be cut into rough, hilly country with numerous ravines and steep valleys, because the short streams flowing down the steep scarp face can erode so rapidly. The back slopes commonly are smooth. Cuestas are common in Arizona and New Mexico and along the Atlantic and Gulf coasts of the U.S. (W. C. C.)

**CUEVA, JUAN DE LA** (1543?-1610), Spanish dramatist and poet, and historically important as a precursor of Lope de Vega, was born at Seville. He based his plays (pub. 1588) on classical sources (*Tragedia de Ayax Telamón*), Spanish historical legend (*Los siete infantes de Lara*), contemporary history (*El saco de Roma*) and novelesque subjects (*El degollado*, "The beheaded"). *El infamador* ("The slanderer") is a distant fore-runner of the Don Juan plays. Although capable of writing good dramatic scenes, he lacked the ability to construct plots and fell into ridiculous improbabilities. Most of his verse is commonplace, though some poems show that he could write well. He expressed his literary theories in the *Ejemplar poético* (1606). (J. Gs.)

**CUI, CÉSAR ANTONOVICH** (1835-1918), Russian composer of operas, songs and piano music, music critic and military engineer. Born at Vilna, Jan. 6 (old style; 18, new style), 1835, he was the son of a French officer, a prisoner of 1812 who remained in Russia after the war, and a Lithuanian. Cui began to compose as a boy, imitating Chopin, and received lessons in composition from Stanislaw Moniuszko, but in 1851 he was sent to St. Petersburg, where he entered the school of engineering, and, in 1855, the academy of military engineering, becoming a lecturer there in 1857. In 1878 he became professor of fortification—his pupils included Gen. M. D. Skobelev and Nicholas II—and he retired with the rank of lieutenant general.

Friendship with Balakirev and Dargomyzhski developed his musical interests: he began to compose copiously and, although he had no Russian blood, became a pugnacious journalistic champion of the Russian nationalist school. From 1864 to 1877 he was music critic of the *St. Peterburgskiy vedomosti*, and later he became a successful propagandist of Russian music in Belgium and France, notably with his *La musique en Russie* (1881). Cui's own music has little Russian flavour and of his ten operas only the first, *The Prisoner of the Caucasus* (begun 1857, produced 1883),

the last, *The Captain's Daughter* (St. Petersburg, 1911) and the one-act *Feast in the Time of the Plague* (Moscow, 1901) are on Russian subjects, all by Pushkin. He turned more readily to French sources: Victor Hugo, Jean Richépin, Dumas père, Maupassant and Prosper Mérimée, and his only moderately successful operas are based on Heine's *William Ratcliff* (St. Petersburg, 1869) and Maupassant's *Mam'selle Fifi* (Moscow, 1903). Cui is at his best in the miniature forms, notably his short piano compositions ranging in style from the Schumannesque to the tasteful salon-piece, and in his songs. He died at Petrograd, March 24, 1918.

See Comtesse de Mercy-Argenteau, *César Cui: esquisse critique*. (1888). (G. Ab.)

**CUIABÁ**, capital of Mato Grosso state, Braz., is situated upon the Cuiabá river, a tributary of the Rio Paraguay. Pop. of the *município* (1950) 56,204; city 23,745. It lies at 541 ft. elevation, has an annual average temperature of about 80° F. and an average annual rainfall of 55 in. Cuiabá is not served by a railroad but may be reached by steamer from La Plata, by river boat from Corumbá and by road from Campo Grande. There is an airport. The city was founded by Paulista gold hunters in 1719 and became the centre of an important gold-mining region in the 18th century. Agriculture and stockraising are the main economic activities, but are limited by the isolation of the area, the lack of markets and the sparse population. (J. L. Tr.)

**CUIRASSIERS**, a kind of heavy cavalry, originally developed out of the men-at-arms or *gendarmes* forming the heavy cavalry of feudal armies. Their special characteristic was the wearing of full armour, which they retained long after other troops had abandoned it. Hence they became distinguished as cuirassiers. The first Austrian corps of *kyrissers* was formed in 1484 by the emperor Maximilian and was 100 strong. In 1705 Austria possessed 20 regiments of cuirassiers. After the war of 1866, however, the existing regiments were converted into dragoons. Russia likewise in modern times abolished all but a few guard regiments of cuirassiers. The Prussian cuirassiers were first so called under Frederick William I, and in the wars of his successor, Frederick the Great, they bore a conspicuous part. After the Seven Years' War they ceased to wear the cuirass on service, but after 1814 these were reintroduced, the spoils taken from the French cuirassiers being used to equip the troops. In France the cuirassiers date from 1666, when a regiment was formed. During the first empire many regiments were created, until in 1812 there were 14. The number was reduced after the fall of Napoleon, but was again increased in the period previous to World War I when the French regiments alone in Europe wore the cuirass on all parades and at maneuvers.

**CUJAS, JACQUES** (latinized as *JACOBUS CUIJACIUS*) (1522-1590), French jurist and scholar, a leader of the school of humanists who in the 16th century gave new impetus to the study of Roman law which accompanied the revival of interest in the classical literature, was born in 1522 at Toulouse, where his father was a fuller. He taught himself Latin and Greek before studying law under Arnoul Ferrier, then professor at Toulouse. He rapidly gained a great reputation as a lecturer on Justinian and in 1554 was appointed professor of law at Cahors. About a year after, M. de L'Hôpital called him to Bourges, but F. Douaren, who also held a professorship at Bourges, stirred up the students against the new professor, and such was the consequent disorder that Cujas yielded and accepted an invitation he had received to the University of Valence. Recalled to Bourges on the death of Douaren in 1559, he remained there until 1567, when he returned to Valence. There he gained a European reputation and collected students from all parts of the continent, among whom were Joseph Scaliger and J. A. de Thou. In 1573 Charles IX appointed Cujas counselor to the *parlement* of Grenoble, and the following year a pension was bestowed on him by Henry III. Margaret of Savoy induced him to remove to Turin; but, after a few months, in 1575 he once more took his old place at Bourges. Driven from that city by the religious wars, he was called by the king to Paris, where the *parlement* granted him permission to lecture on civil law in the university. A year after, however, he finally took up his residence

at Bourges, where he remained until his death in 1590.

Cujas devoted his life to scholarship and teaching. In the religious wars which filled all the thoughts of his contemporaries he steadfastly refused to take any part. *Nihil hoc ad edictum praetoris*, "This has nothing to do with the edict of the praetor," was his usual answer to those who spoke to him on the subject. His surpassing merit as a jurisconsult was that he turned from the ignorant commentators on Roman law to the Roman law itself, which he studied as literature and in its historical context. He collected more than 500 manuscripts, but his library was broken up after his death and a great part lost. His emendations, of which a large number were published under the title of *Animadversiones et observationes*, were not confined to legal texts, but extended to many of the Latin and Greek classical authors. In jurisprudence his study was by no means limited to Justinian; he recovered and published, with explanations, a part of the Theodosian Code; and he procured the manuscript of the Basilica, a Greek abridgement of Justinian, afterward published by C. A. Fabrot (see *BASILICA*). He also composed a commentary on the *Consuetudines Feudorum* and on some books of the Decretals. In the *Paratitla*, or summaries which he made of Justinian's Digest and Code, he condensed into short axioms the elementary principles of law and gave definitions remarkable for their clarity and precision.

The complete edition of his works (Neville, 1577) is very scarce. The edition of Colombet (1634) is incomplete. Fabrot, however, collected the whole in the edition which he published at Paris (1658), and which was reprinted at Naples (1722, 1727), and at Naples and Venice (1758) with an index forming an 11th volume.

Spangenberg, *Jacob Cujas und seine Zeitgenossen* (1822). (L. N. B.; X.)

**CULDEES**. "Culdee," an anglicizing of the two Irish words *céle*, a "companion" or "friend," and *Dé*, "God," was applied originally to monks and nuns, but from the 8th century onward more particularly to groups of ascetics in various parts of Britain, principally in Ireland and Scotland. It is not possible always to distinguish these Culdees clearly from other contemporary ascetics, but it may be said that generally speaking they stood for the old ways of the Celtic Church (*q.v.*) in religion as against Roman influences in the 7th and 8th centuries and against continental religious orders after the Norman Conquest. To their activities is due the preservation of most of the surviving Irish rules, penitentials, martyrologies and service books, such as the 8th-century "Rule of Máelruain" and the 9th-century "Observances of Tal-lacht," and it is in this revival and love of native monastic ways of life and worship and not, as has sometimes been suggested, in the rule of Chrodegang of Metz (*c.* 755) that their origin must be sought. Organization was not their strong point (another Celtic characteristic) and there seems to have been considerable diversity, but by and large they appear as secular clerics living under a superior within a common enclosure attached to some established community. There they practised a strict and old-fashioned way of life, busying themselves with caring for the sick and poor and for the choral parts of the church services. After the Norman Conquest they gradually disappeared before the continental religious orders or were absorbed in the new foundations of canons regular. Information about them comes chiefly from their supplanters and must be used with caution, being subject to both national and ecclesiastical bias. In places such as Armagh in Ireland and St. Andrews in Scotland their name and endowments survived until the Reformation. At York the flourishing Culdee community found there by King Athelstan in the 9th century was transformed into St. Leonard's hospital in the 12th. As late as 1190 Giraldus Cambrensis referred to Culdees still existing at Bardsey Island and Beddgelert in north Wales, and, while noting the hostility with which the Cistercians regarded them, he praised the piety and asceticism of their lives.

**CULEBRA ISLAND** is the smallest of the three offshore islands under the jurisdiction of Puerto Rico. The island is about equidistant between the east coast of Puerto Rico and St. Thomas of the Virgin Islands. Passenger and mail launches from Fajardo to St. Thomas often stop at Culebra Town, formerly Dewey, located on the island's excellent harbour called Puerto Grande. The island, colonized in 1879, is 10 sq.mi. in area and in 1960 had a population of 573; (1950) 887. Because of its fine harbour, the U.S. navy has occupied one-third of the terrain and used its port as a base for naval maneuvers. Grazing is the main industry of the island; no sugar cane is cultivated, but some coconuts and local crops are grown. Fishing in the surrounding waters is excellent. Water is scarce, and during the dry season the collected rain water must be supplemented from Puerto Rico. Three small keys lie close to Culebra Island. One of these, Culebrita Island, was declared by Theodore Roosevelt a sanctuary for wild birds; however, in recent years this order has not been respected.

(T. G. Ms.)

**CULIACÁN**, capital of the state of Sinaloa on the west coast of Mexico. Pop. (1960) 85,024. The city is located on a small coastal plain (elevation 175 ft.) at the foot of the lofty Sierra Madre Occidental on the left bank of the Culiacán river. Along the river bank, the Jardín Rosales contains many cultivated plants and a large variety of bird life. Although generally hot and semi-arid, Culiacán has an average precipitation of 24 in. during the summer rainy season. An elaborate irrigation system in the Culiacán river valley provides for a great variety of crops, including maize, sugar cane, chick peas, beans, chilies, melons, potatoes, groundnuts, tobacco, oranges, limes, bananas and grapes. Culiacán is connected by rail with the port of Guaymas on the Gulf of California and is on the west coast artery of the Pan-American highway. The city was founded in 1531 by Nuño de Guzmán, conqueror of Nueva Galicia, and played an important part in early Spanish-colonial days as a base for expeditions. (H. R. Hv.)

**CULION ISLAND** is one of the Calamian Islands (q.v.) in the province of Palawan (q.v.), Philippine Islands. Area 150 sq.mi. It is the location of Culion Reservation (pop. [1960] 4,785), a leper colony founded in 1906. The lepers are gathered from all parts of the Philippines and are kept at government expense. Excellent medical and hospital services are furnished free of charge, and many cures have been made. The local government is administered by the lepers themselves, who, so far as possible, live normal village lives in the healthful climate, raising rice and coconuts.

**CULLEN, PAUL** (1803–1878), Irish cardinal and archbishop of Dublin, was born near Ballymore, County Kildare, on April 27, 1803, and educated first at the Quaker school at Carlow and afterward at Rome. There he joined the Urban College of Propaganda and, after passing a brilliant course, was ordained in 1829. He then became vice-rector and afterward rector of the Irish National college in Rome. During the Mazzini revolution of 1848 he was rector of the Urban college. In 1849 Cullen was nominated as successor to the primatial see of Armagh. Taking a strong line on the educational question which was then agitating Ireland, he played a leading part in the National movement of 1850–52. In May of the latter year he was translated to Dublin, and soon a divergence of opinion broke out between him and the more ardent Nationalists. As time went on, his distrust of the National movement grew deeper; and in 1853 he sternly forbade his clergy to take part publicly in politics. He was made cardinal in 1866, being the first Irish cardinal. Cullen was an energetic administrator, and churches and schools rose throughout his diocese; the excellent Mater Misericordiae hospital and the Catholic University of Ireland are lasting memorials to his zeal. He took part in the Vatican council as an ardent infallibilist. The cardinal died in Dublin on Oct. 24, 1878. (E. TA.; X.)

**CULLEN**, a royal burgh and popular holiday resort on a Moray firth bay in Banffshire, Scot., 58 mi. N.W. of Aberdeen by road.

Pop. (1961) 1,924. Its appeal lies in its scenery, sandy beaches, cliffs, hills, woods and moors, and in its historical associations. William the Lion first granted its royal charter and Robert the Bruce endowed a chaplaincy for prayer for his wife, Elizabeth de Burgh, who died there.

The Cullen burn enters the sea at the western boundary between the Seatown, inhabited by the fishing community, and the golf links. Southward, on sloping ground, stands the new town with its wide, straight streets dating from 1820–30 when the original township, which stood one mile south, was cleared to improve the amenities of Cullen house, the early-17th-century Scots baronial seat of the earls of Seafield. The nearby parish kirk of St. Mary existed by 1236; later additions produced the present cruciform structure. (W. D. McH.)

**CULLODEN**, a tract of moorland in Inverness-shire, Scot. It forms part of the northeast of Drummoissie moor, and is situated about 6 mi. E. of Inverness by road. It is celebrated as the scene of the battle of April 16, 1746, by which the fate of the house of Stuart was decided. By Highlanders the battle is sometimes described as the battle of Drummoissie. Several memorials, including a tall cairn, have been erected, and scattered stones inscribed with names of clans act as grave markers of fallen highlanders.

About one mile to the southeast of the field, on the right bank of the Nairn, is the plain of Clava, containing several stone circles (varying in circumference from 12 to 140 yd.), monoliths, cairns and other prehistoric remains.

**Battle of Culloden.**—Concentrating his forces, Prince Charles Edward, the Young Pretender, awaited the British on Drummoissie moor. Hearing, however, that the duke of Cumberland had halted at Nairn, eight miles away, to celebrate his 25th birthday (April 15), Charles, with Lord George Murray, decided to surprise his camp; but the long night march over the moors was too much for the tired and starving Highlanders and they returned to their old position, more exhausted and depressed than ever. Early on the morning of April 16, Cumberland made contact with the pretender's army. The Jacobites, about 5,000 strong, were drawn up in two widely separated lines, with a small reserve of horse, one flank resting on the park walls of Culloden house. Their opponents, 9,000 strong, were also in two lines, at a distance of 50 paces, with cavalry on each flank and a reserve of Highland irregulars. The battle began with an artillery duel, in which the 18 well-served guns on the Hanoverian side caused great distress to the Highlanders, who sought to escape their fire by attack. The regular British infantry awaited them in three ranks, the first kneeling, the second stooping and the third standing.

Cumberland had trained each of his soldiers to engage the man to his right front, so evading the Highlander's target and thrusting under his raised sword arm. The Highlanders on the left failed to attack effectively; on the right they broke through, but were taken in flank by supports from the second line and thrown back in great confusion. Seeing this, the Jacobite centre and left lost heart and retreated, the regulars following up and causing heavy losses with their musketry fire. At the same time the dragoons broke through the walls which were protecting the Jacobite flanks and attacked the second line in the rear.

The Highlanders, finding themselves outflanked, broke and fled. About 1,000 were killed in the battle or the subsequent pursuit, and the same number were taken prisoner; Cumberland lost only 50 killed and 200 wounded.

**BIBLIOGRAPHY.**—*Culloden Papers* (1815); D. G. Warrand (ed.), *More Culloden Papers*, 5 vol. (1923–30); A. and H. Taylor (eds.), *1745 and After* (1938); Sir B. Seton and Jean Arnot (eds.), *Prisoners of the '45*, 3 vol. (1928–29). (G. S. P.)

**CULLUM, GEORGE WASHINGTON** (1809–1892), U.S. army officer and author, was born in New York city on Feb. 25, 1809. He entered the U.S. Military academy at West Point in 1829 and after graduation in 1833 received a commission in the corps of engineers. He served as an engineer officer with the U.S. army during the Mexican War and from 1848 to 1855 taught practical engineering at West Point. At the outbreak of the Civil War, Cullum became aide-de-camp to Gen. Winfield Scott, then com-

mander in chief of the U.S. army. He later served on the staff of Gen. H. W. Halleck, first in the department of Missouri and then in Washington, D.C., after Halleck became general in chief of the armies of the U.S. Upon retiring from active service, as a colonel, in 1874, Cullum devoted himself to literary, scientific and military studies.

Of his many published works he is best known for his *Biographical Register of the Officers and Graduates of the U.S. Military Academy From 1802 to 1850*, published in 1850. Second and third editions extended the coverage to 1891. At his death on Feb. 28, 1892, Cullum left provision in his will for continuance of the *Biographical Register*, and supplements were published at intervals thereafter. (H. C. T.)

**CULMANN, KARL** (1821-1881), German engineer whose method of graphostatics has been used extensively in many problems of engineering and mechanics, was born in Bergzabern, Ger., on July 10, 1821, the son of a Bavarian clergyman. At 17 he matriculated in the engineering school of the Polytechnical institute in Karlsruhe, after which he entered the Bavarian civil service as an apprentice on the Hof railway section, where he remained until 1847. For the next three years he traveled in England, Ireland and North America, re-entering the civil service on his return. With an appointment to the faculty of the Polytechnical institute in Zürich, Switz. (1855), he began a career of teaching and research. In 1864 he made a valuable report following his investigation of the wild mountain streams of Switzerland, the control of which was a seasonal problem. His most important work, however, was concerned with the problem of determining the distribution of stresses in structures. With the publication of *Die graphische Statik* (vol. 1, 1865, no others published; 2nd ed. 1875), he presented a survey of all that had been done up to that point toward the solution of static problems by the graphic method, at the same time laying a foundation for its use as an exact science.

In 1880, Culmann was made honorary doctor of the faculty of philosophy at the University of Zürich. He died at Reisbach near Zürich on Dec. 9, 1881.

**CULMINATION**, in astronomy, the term given to the passage of a heavenly body over the meridian of a given place. Two culminations take place in the course of the day, one above and the other below the pole. The first is called the upper, the second the lower. Either or both may occur below the horizon and therefore be invisible.

**CULPEPER'S REBELLION** (1677-79), one of the first popular uprisings in the American colonies. The Albemarle colony, in the northern part of Carolina, consisted of about 4,000 persons engaged primarily in the raising of tobacco to be sold through New England merchants and shippers. Enforcement of the navigation acts denied the colonists a free market outside of England, and heavy duties placed on tobacco kept the northern merchants from their harbours. Feelings of repression found an object in the deputy governor, Thomas Miller, who was also customs collector. The insurrection came to a head in 1677, with John Culpeper and George Durant as leaders. The first act of the rebels was to imprison Miller and most of his council. They then took over all public records, established courts of justice, appointed judges and convened an assembly. On Dec. 3, 1677, they issued a manifesto entitled "Remonstrance of the Inhabitants of Paspatancke to All the Rest of the County of Albemarle," signed by 34 persons and outlining the grievances justifying their rebellion.

For two years, with Culpeper as governor, they capably exercised all the powers and duties of government. An appointed governor sent from England the following year died before reaching Carolina. The settlers, hopeful of a just settlement, sent Culpeper to England, promising submission to proper authority. Miller had in the meantime escaped and was in England to greet Culpeper with charges of treason and embezzlement. Culpeper willingly submitted to trial and found support in the influential earl of Shaftesbury, one of the proprietors of Carolina, who defended Culpeper by asserting that no regular government existed in Albemarle and that his actions were not treasonable. Culpeper was acquitted. (W. S. P.)

**CULROSS** (locally pronounced *Coo-rus*), a royal and small burgh of Fifeshire, Scot., 6 mi. W.S.W. of Dunfermline by road. Pop. (1961) 514. It is attractively situated on a hillside sloping gently to Torry bay in the Firth of Forth. Its early history has much to do with that of the church. St. Serf (or Servan) probably founded a church and cemetery there in the 5th century, and for years after his death the townsfolk celebrated his feast (July 1) by walking in procession bearing green boughs. It is the reputed birthplace of St. Kentigern (also called Mungo), the first bishop of Glasgow. These religious associations, coupled with the fertility of the soil, led to the founding of a Cistercian abbey in 1217. Of this only the western tower and choir remain to form the parish church. James VI made Culross a royal burgh in 1588. All the old industries of the town—the coal mines, saltworks, linen manufactures and the making of iron "girdles" (for making oat cakes)—have disappeared. Culross is an outstanding survival of 17th- and 18th-century domestic architecture, with houses, which often have dormer windows, huddled along narrow cobbled streets. The older buildings were put under the care of the National Trust for Scotland, which continued their maintenance and restoration. These include the "Palace," built (c. 1597-1611) by Sir George Bruce, with paneled and painted rooms, the Abbey house, built by his brother in 1608, and the "Study," a 17th-century house facing the mercat (market) cross. Bishop Leighton's lodgings, the Snuff Maker's house (1763), the "House with the Evil Eyes" and the 17th-century townhouse are further examples.

Dunimarle castle ( $\frac{1}{2}$  mi. W.), containing a fine art collection, adjoins the site of the castle where, according to tradition, Macbeth slew the wife and children of Macduff.

**CULTURAL ANTHROPOLOGY:** see SOCIAL ANTHROPOLOGY.

**CULVER CITY**, an industrial and residential city in southwestern Los Angeles county, Calif., U.S., best known for its motion-picture production. About 1819 the area was used for cattle grazing and barley fields. In 1912 the Culver Investment company acquired the section. Harry H. Culver, after whom the city was named, proceeded to subdivide the local area in 1913. By 1914 several shops had appeared. Motion pictures began to be made there as early as 1915. Thomas H. Ince needed a stream for an Indian canoe scene and La Ballona creek in Culver City provided the answer. Culver City is ranked with Hollywood in motion-picture production.

Culver City was incorporated as a chartered city on Sept. 20, 1917. In addition to motion pictures, its industries include pen manufacture, aircraft production and wearing apparel. For comparative population figures see table in CALIFORNIA: Population. (J. M. Wo.)

**CULVERWEL, NATHANAEL** (1618?-1651?), English philosophicoreligious thinker, whose mixture of empiricism, a legislative ethics and rationalism probably influenced Locke, was most likely a son of Richard Culverwel, rector of St. Margaret's, Friday street, London. Culverwel entered Emmanuel college, Cambridge, in 1633 and was elected to a fellowship in 1642. His last years appear to have been clouded by mental disorder.

His writings were posthumously published by an Emmanuel colleague, William Dillingham: first six sermons under the title *Spiritual Opticks* (Cambridge, 1651); then his complete works as a single volume (London, 1652). His best-known essay, *An Elegant and Learned Discourse of the Light of Nature*, was composed as the introduction to a large work, in which Culverwel hoped to defend both reason against its more violent adversaries and faith against Arian rationalism. It is not closely reasoned but has been much admired for its passionate rhetoric, although it labours under the weight of scholastic-Aristotelian authorities.

Culverwel is usually described as one of the Cambridge Platonists (q.v.), and certainly that part of the *Discourse* which glorifies reason reveals Benjamin Whichcote's influence. But he did not entirely shake off the influence of Calvinism, which is

particularly marked in his sermons. Reason is important, according to Culverwel, because it discovers to us the need for revelation and the existence of a divine law; but God's will, not reason, is the "rule of good and evil." Human reason does not, as the Platonists thought, participate in divine reason; it dimly reflects it. Nor does Culverwel accept the Platonist view that the mind is active in knowledge; the understanding, he says, is "a glass not prejudiced, but nakedly receiving, and faithfully returning, all such colours as fall upon it."

**BIBLIOGRAPHY.**—See J. Cairns's preface to J. Brown's edition of the *Discourse* (1857). Of the works listed under CAMBRIDGE PLATONISTS see especially Tulloch, Powicke, Pawson and Campagnac (who includes the *Discourse*). See also W. C. de Pauley, *Candle of the Lord* (1937); A. C. Scupholme, "Nathanael Culverwel," in *Theology* (1939). On Culverwel's relation to Locke see W. von Leyden, *John Locke's Essays on the Law of Nature* (1954). (J.N. A. P.)

**CULZEAN**, a castle in Ayrshire, Scot., 4 mi. W. of Maybole, built between 1771 and 1792, is an outstanding example of the work of Robert Adam. It stands on cliffs and incorporates a medieval keep of the Kennedys, who were feudal overlords in south-west Scotland. Features of the castle, which was acquired by the National Trust for Scotland in 1945, are the magnificent oval staircase, the staterooms with painted ceilings and the armoury. The top flat was given to Gen. (later Pres.) Dwight D. Eisenhower as a Scottish residence for use during his lifetime in gratitude for his services to the Allied cause during World War II. Beneath the castle are caves, or caves, said to have been a rallying point of King Robert the Bruce in his struggles against the English.

(L. M. Cr.)

**CUMAE**, an ancient city on the west coast of Campania, Italy, about 12 mi. W. of Naples, on a volcanic hill, overlooking the plain of the Volturno river.

Cumae (Gk. *Cyme*) was founded about 750 by Euboean Greeks from Chalcis and Eretria who had previously settled on the nearby island of Pithecusae (Ischia); it was probably the oldest Greek mainland colony in the west. Cumaeans pirates settled at Zancle (Messina) before the city's official foundation about 730 by colonists from Cumae and Chalcis, and Naples (Gk. *Neapolis*, "New City") is also said to be a Cumaeans foundation. The Cumaeans controlled the most fertile portion of the Campanian plain and were probably the means of bringing the Etruscans into contact with Greek culture. In 524 B.C. under the tyrant Aristodemus they withstood an attack by the Etruscans of Capua, the Daunians of the district of Nola, and the Aurunci of the Mons Massicus and in 508 helped the Romans against the Etruscans at the battle of Aricia. A renewed Etruscan attack was repelled with the help of Hiero of Syracuse, who in the battle of Cumae of 474 B.C. defeated the Etruscan fleet. The Samnites finally destroyed the Etruscan supremacy by the capture of Capua about 440 (see CAMPANIA; CAPUA [ancient city]), and the Greeks of Cumae were overwhelmed in 428 or 421. The beautiful series of Greek coins from the town now ended, and Oscan, one of the Italic dialects, became its language (though in many respects the Greek character of the town survived) until about 180 B.C. when the Cumaeans asked for permission to use Latin for public purposes. Cumae had already come under the supremacy of Rome in 338. In the Hannibalic wars it remained faithful to Rome. Under the empire it was a quiet country town, in contrast to the gay and fashionable Baiae (Baia), though the nearby lakes of Avernus and Lucrinus became naval bases in 37 B.C. In the Gothic wars the acropolis of Cumae was, except for Naples, the only fortified town in Campania, and it retained its military importance until it was destroyed as a nest of pirates by the Neapolitans in 1205, after which time it was deserted.

The acropolis hill (269 ft. above sea level), a mass of trachyte which has broken through the surrounding tufa, lies hardly 100 yd. from the low sandy shore. It is traversed by caves, and a long gallery, cleared in 1932, which may have been identified with the *antrum* (cave) famous in legend as the seat of the oracle of the Cumaeans Sibyl (see SYBIL). The acropolis has only one approach, on the southeast; on all other sides it falls away steeply and in classical times the sea reached its foot. Remains of fortifications of all ages run around the edge of the hill; some of the origi-

nal Greek work, in finely hewn rectangular tufa blocks, exists on the east. Within the acropolis stood two Greek temples, one of Apollo, both restored in Roman times and later converted into Christian basilicas.

To the south of the town, just outside the wall, is the amphitheatre. A mile to the east of Cumae, the *Via Domitiana* passes through the Arco Felice, an arch of brick-faced concrete 63 ft. high which spans a cutting through Monte Grillo, made by Domitian to shorten the course of the road. The Roman underground road ( $\frac{3}{4}$  mi.) known as the Grotto della Pace leads from southeast of Cumae through Monte Grillo to the shores of Avernus (Averno) lake. Pre-Hellenic (9th to 8th centuries B.C.) and Greek, Samnite and Roman graves near Cumae have yielded many important objects.

See A. Maiuri, *The Phlegraean Fields* (Eng. trans.) pp. 93–131 (1947).

**CUMANA**, a city of Venezuela and capital of Sucre state, is on the Río Manzanares, one mile from the river mouth where Puerto Sucre, its port, is located. Pop. (1961) 71,563. The city has an elevation of 52 ft. and an enervating climate which averages 83° F. It is 180 mi. from Caracas and 62 mi. from Barcelona with which it is connected by a highway. The city has an airport. Cumana is subject to frequent earthquakes, the severest being in 1530, 1766, 1797, 1853 and 1929. Coffee, cacao, sugar, tobacco, beans and a variety of excellent fruits are raised in the vicinity. Near the city is a major cotton mill. A small but important fishing industry is carried on. Missionaries were first in the region and in 1521 González Ocampo established near the present site a settlement that was soon destroyed by Indians. Cumana was founded under the name Nueva Córdoba by Jacome Castellón in 1523 and claims to be the oldest European settlement on the South American mainland. English pirates sacked the town in 1576. Between about 1590 and 1625 the city served as a base of operations against the Dutch, who came illegally to Punta de Araya for salt. Cumana enjoyed a profitable trade with neighbouring settlements and with Spain throughout much of the colonial period. Famous old Venezuelan families with Spanish colonial roots give the city a prestige which is nationally recognized. (J. J. J.)

**CUMBERLAND, EARLS AND DUKES OF.** The earldom of Cumberland was held by the family of Clifford (*q.v.*) from 1525 to 1643, when it became extinct by the death of Henry, the 5th earl. HENRY (1493–1542), 11th Lord Clifford, was created earl of Cumberland by Henry VIII in 1525. He held Skipton castle against the rebels led by Robert Aske in 1536. His son HENRY (1517–70) was twice married. By his first wife, Eleanor, the daughter of Charles Brandon, duke of Suffolk, and of Mary Tudor, daughter of Henry VII, he left an only daughter, Margaret (1540–96), who married Henry Stanley, 4th earl of Derby, and in 1557 was by many regarded as the rightful heiress to the English throne. By his second wife he left two sons and a daughter. His elder son, GEORGE (1558–1605), a great mathematician and navigator, made nine voyages of exploration and plunder, mainly to the West Indies, sometimes with the support of Queen Elizabeth I. He commanded the "Bonaventure" against the Spanish Armada (1588). George left no sons, and he was succeeded in the barony by his daughter Anne and as earl of Cumberland by his brother FRANCIS (1559–1641). Francis' son HENRY (1592–1643), 5th earl of Cumberland, supported Charles I in the early months of the Civil War. When he died of a fever at York without issue on Dec. 11, 1643, the earldom became extinct; his new barony of Clifford (created 1628) went to his daughter Elizabeth (1613–91), wife of Richard Boyle, earl of Cork and Burlington, and the Cumberland estates passed to his cousin Anne (d. 1676), Baroness Clifford and countess of Dorset, Pembroke and Montgomery.

The title of duke of Cumberland has been held from 1644 by various members and connections of the English royal family. Prince RUPERT (1619–82), son of Frederick V, elector palatine and king of Bohemia, was created duke of Cumberland in 1644 by his uncle, Charles I. The title lapsed when Rupert died without legitimate issue, but was revived in 1689 in favour of GEORGE (1653–1708), prince of Denmark, who had married (1683) Princess Anne (afterward Queen Anne). The title was held from 1726 until his death in 1765 by WILLIAM AUGUSTUS, duke of Cumberland (*q.v.*)

second surviving son of George II. William Augustus was unmarried; the title lapsed at his death and was granted in 1766 to HENRY FREDERICK (1745–90), 4th son of Frederick, prince of Wales, and brother to George III. The fifth creation (1799) was in favour of ERNEST AUGUSTUS (q.v.), fifth son of George III. On the death of his brother William IV in 1837, Ernest Augustus became king of Hanover under the Salic law, and on his death in 1851 the title descended with the kingdom of Hanover to his son GEORGE FREDERICK (1819–78), afterward King George V of Hanover. Hanover was annexed by Prussia in 1866 but King George never renounced his rights. His son ERNEST AUGUSTUS (q.v.) was known as the duke of Cumberland during his father's lifetime. He inherited the duchy of Brunswick in 1884, but was prevented from becoming reigning duke by a federal decision inspired by Prussia in 1885 and repeated in 1907 (see BRUNSWICK). The duke never formally renounced the throne of Hanover, and the hostility between his family and the Hohenzollerns was only ended in 1913 when his son ERNEST AUGUSTUS (1887–1953) married Princess Victoria Louise, daughter of the Prussian emperor William II. The elder Ernest Augustus then renounced his rights to his son, who became sovereign ruler as duke of Brunswick. He was obliged, with other German princes, to abdicate on Nov. 8, 1918; a Titles Deprivation act (1917) and an order in council (1919) effectively deprived father and son of their United Kingdom titles. ERNEST AUGUSTUS (1914– ), son of the last duke of Brunswick, successfully claimed British citizenship in 1955, and his claim was upheld by the house of lords in 1956; he was thus entitled to petition the crown for a revival in his favour of the title of duke of Cumberland.

**CUMBERLAND, RICHARD** (1631–1718), English moral philosopher and bishop of Peterborough, son of a London citizen, was born in the parish of St. Bride's, London, on July 15, 1631. He was educated at St. Paul's college, London, and Magdalene college, Cambridge, which he entered in 1648. He was made a fellow in 1656 and began the study of medicine, but accepted preferment first to the rectory of Brampton in Northamptonshire (1658) and then to the rectory of Allhallows at Stamford (1667). Although not ambitious for office he was named bishop of Peterborough in 1691, partly because of his staunch Protestantism. He died on Oct. 9, 1718.

Cumberland's works fall into two groups: historical and philosophical. Like many other Cambridge men of his time he was greatly interested in Hebraic antiquities and published in 1686 *An Essay Toward the Recovery of the Jewish Measures and Weights, Comprehending Their Monies; by the Help of Ancient Standards Compared with Ours of England*. His domestic chaplain and son-in-law Squier Payne prepared for posthumous publication a translation and commentary on *Sanchoniatho's Phoenician History* (1720), the authenticity of which Cumberland did not doubt. Cumberland thought it threw light on the origins of idolatry; in a manner typical of Cambridge scholarship he identified the personages mentioned by Sanchoniathon with a variety of Old Testament characters. Payne also published a sequel to the work: *Origines gentium antiquissimae; or Attempts for Discovering the Times of the First Planting of Nations; in Several Tracts* (1724).

Cumberland's reputation rests on his *De legibus naturae disquisitio philosophica* (1670), "Wherein the essence, the order, the publication, and the obligation of these laws are deduced from the nature of things and the principles of Mr. Hobbes' philosophy are examined and confuted." An abridged version by James Tyrrell appeared in 1692 as *A Brief Disquisition of the Laws of Nature According to the Principles Laid Down by the Rev. Dr. Cumberland's Latin Treatise*; the best English translation is that of John Towers, *A Philosophical Enquiry into the Laws of Nature* (1750).

Cumberland's starting point is Grotius. But whereas Grotius—or so Cumberland interprets him—rested the authenticity of his laws of nature on the general agreement of civilized nations, Cumberland looked for a more secure philosophical foundation. He is very conscious of the writings of Hobbes, against whom his work is largely directed; his object, in general terms, is to show in opposition to Hobbes that there are firmly established laws of nature which make it desirable for us to pursue the common good rather than our own particular advantage. Although he was sympathet-

ically inclined toward, and influenced by, Cambridge Platonism he did not wish to rely upon "the short and easy expedient" of the Platonists by maintaining that natural laws are innate principles; or to rest his case upon scriptural authority. "Our sole design and aim here," he writes, "is to establish the Law of Nature just so far as and no farther than, we are conscious of such a Law from our own natural Reason, Observation and Experience."

The basic doctrine on which Cumberland's theory depends is that the whole is exactly the same as all its parts taken together, from which it follows that whatever preserves the whole preserves the parts. His "great moral principle" is "That the fullest, most vigorous Endeavour, of each and all rational Agents, in Promoting the Common Good of the whole rational System, contributes effectually to the Good of each single Part in such a System; Under which Whole, or System, the single, individual Happiness of each, and all of us, is essentially contained: on the contrary, that Acts, opposite to such a Propensity, must produce Effects opposite, and by Consequence, amongst many other Evils, involve us, and each of us, in Misery." Thus Cumberland's reply to Hobbes's egoism is that in fact the happiness of the individual is ensured only if he works for the common good. Right action, he argues, is that action which takes the shortest means to the common good; and such action will also be naturally good, morally good, beautiful, decent and praiseworthy. Thus all the principal moral concepts are related to the single idea of the energetic pursuit of the common good. Similarly, more particularized moral duties (e.g., gratitude, promise-keeping, familial responsibilities) are all of them specific applications of the single, general moral law. God, as rational, uses this law to bind all rational beings and supports it by sanctions.

Since he defines moral action in terms of ends and lays great stress on happiness, Cumberland has sometimes been described as the father of English utilitarianism. Equally, he is the father of the sort of rationalism exemplified in the ethics of Samuel Clarke, who was greatly influenced by Cumberland. For much of Cumberland's argument is directed toward showing that the pursuit of the common good is the conduct "naturally fitting for a rational being"—a "fitness" which can be quite as certainly apprehended as the mathematical relation of congruity. He is also one of the first to attempt to work out a quasi-mathematical morality, a "moral calculus" of the sort later developed by Hutcheson and Bentham. Indeed, a surprising number of the trends in later moral philosophy can be detected within Cumberland's verbose, prosaic, not wholly consistent work. He was better at proposing ideas than at working them out.

**BIBLIOGRAPHY.**—S. Payne, *Life of Cumberland*, being Appendix iv of Towers' 1750 edition of the *Laws of Nature*. See also E. Albee, *A History of English Utilitarianism* (1902); F. C. Sharp, "The Ethical System of Richard Cumberland, and Its Place in the History of British Ethics," *Mind* (1912).

**CUMBERLAND, RICHARD** (1732–1811), English dramatist whose reputation rests mainly on his sentimental comedies, which suited the temper of the time and showed skill in stagecraft, was born in Cambridge on Feb. 19, 1732. He was the great-grandson of the bishop of Peterborough, and his father, Denison Cumberland, became in turn bishop of Clonfert and of Kilmore. His mother was Joanna, the daughter of the great scholar Richard Bentley. Cumberland was educated at Westminster school and Trinity college, Cambridge. He had just begun to read for his fellowship when he was offered, and accepted, the post of private secretary to the earl of Halifax, first lord of trade and plantations in Newcastle's ministry. In 1761 he accompanied Halifax (who had been appointed lord lieutenant) to Ireland as Ulster secretary and later held other government positions. In 1780 he was sent on a confidential mission to Spain, the expenses of which he strove in vain to recover, and soon after he retired on an allowance of less than half pay. He died in London on May 7, 1811.

Although chiefly famous as a dramatist, Cumberland is also memorable for his *Memoirs* (1806–07), which include a long account of his Spanish mission and reminiscences of politicians and of David Garrick, Samuel Foote and Oliver Goldsmith. He was a good observer of men and manners, but the uneasy self-absorption which Sheridan immortalized in Sir Fretful Plagiary in *The*

*Critic* is apparent. As a dramatist Cumberland met alternately with periods of great success and complete failure, but he continued to write with enthusiasm, and produced at least one, often three, plays a year. His success began with a sentimental comedy, *The Brothers* (1769). Its plot is reminiscent of Fielding's *Tom Jones*, but the characters, the jovial Captain Ironsides and the henpecked Sir Benjamin Dove, are closer to those of Smollet. Sentiment was becoming an important literary force at the time (*Sterne's Sentimental Journey* appeared in 1768, Henry Mackenzie's *Man of Feeling* in 1771), and in giving dramatic expression to the current mood Cumberland gained great popularity. He continued his success with *The West Indian*, which was produced in 1770 by Garrick and subsequently became one of the stock plays of the late 18th-century theatre. The plot is fantastic and the psychology crude, but the play is stageworthy (Cumberland was a master of stage effect) and again a great deal of feeling is extracted from the situations. He followed this with another sentimental comedy, *The Fashionable Lover* (1772).

Although Cumberland's most successful genre was clearly sentimental comedy, he hankered to produce more exalted dramas in the grand style. All through his life he kept by him an early tragedy, *Tiberius in Capreae*, which no manager would produce but which he regarded as his masterpiece, and he attempted to break away into more serious works such as *The Battle of Hastings* (1778) and *The Carmelite* (1784), as well as altering for the stage Shakespeare's *Timon of Athens* and Philip Massinger's *The Bondman* and *The Duke of Milan*. Although he was in general less successful in serious plays, exception must be made for *The Jew* (1794), in which he attempted to depict an avaricious Jew as endowed with humane feelings, and *The Wheel of Fortune* (1795), which contains the part of the misanthropist Penrudock, one of John Philip Kemble's most famous roles.

Cumberland's querulousness in the face of criticism led him to quarrel with many of his contemporaries, including Goldsmith, whom he disliked because of the antisentimentalism of *She Stoops to Conquer*, and Sheridan, who had caricatured him in *The Critic*. Besides his plays and *Memoirs* he produced a series of essays, *The Observer* (1785), and two novels, *Arundel* (1789), epistolary in form, and *Henry* (1795), which adopts Fielding's narrative method.

See S. T. Williams, *Richard Cumberland, His Life and Dramatic Works* (1917). (JN. C.)

**CUMBERLAND, WILLIAM AUGUSTUS, DUKE OF** (1721–1765), English military leader in the Austrian Succession and Seven Years' wars, derived his nickname, "Butcher Cumberland," from his stern suppression of the 1745 Jacobite rebellion. He was born on April 15, 1721, the third but second surviving son of George Augustus, prince of Wales (afterward King George II), and of Caroline of Ansbach, and was created duke of Cumberland in July 1726. He was educated for a naval career but his own preference was for the army, and in April 1740 he was appointed colonel of the Coldstream guards. He was promoted major general in 1742 and fought with conspicuous bravery in the battle of Dettingen (June 27, 1743). He returned to Flanders early in 1745 as captain general of all British land forces and as commander in chief of the allied British, Hanoverian, Dutch and Austrian troops. Attempting to relieve Tournai, he was defeated by Marshal Saxe at the battle of Fontenoy (May 11, 1745).

Cumberland was recalled from Flanders to oppose the invasion of England by Prince Charles Edward (Nov.–Dec. 1745). He followed the Jacobites in their retreat from Derby to Carlisle, but early in Jan. 1746 returned to London. News of Gen. Henry Hawley's failure to relieve Falkirk took Cumberland north again, where he spent six weeks at Aberdeen preparing his army. He won the decisive battle of Culloden on April 16, 1746, after which he remained another three months in Scotland supervising the pursuit and punishment of the rebels. As reward, he was voted an income of £25,000 a year, in addition to his revenue from the civil list.

Cumberland was back in Flanders in 1747, and was defeated by Marshal Saxe at the battle of Lauffeld, near Maastricht (July 2, 1747). When the Seven Years' War broke out he was sent to defend Hanover, but was defeated by the superior forces of Marshal d'Estrées at Hastenbeck, near Hameln, on July 26, 1757. His

troops were subsequently cornered between the North sea and the Elbe river and on Sept. 8 he signed the convention of Klosterzeven, promising to evacuate Hanover. George II repudiated the agreement and Cumberland was disgraced. He resigned all his military commands and retired to Windsor. In the reign of George III he did much to bring about the fall from power of the earl of Bute (1763) and of George Grenville (1765); gradually he regained his early popularity, and his death in London on Oct. 31, 1765, was much regretted.

**BIBLIOGRAPHY.**—A. N. C. MacLachlan, *William Augustus, Duke of Cumberland* (1876); E. Charteris, *William Augustus . . . His Early Life and Times* (1913), *William Augustus . . . and the Seven Years' War* (1925).

**CUMBERLAND**, a county lying in the extreme northwestern corner of England. It has a geographical area (administrative county and Carlisle county borough) of 1,521 sq.mi. Together with the county of Westmorland, the region—which includes the greater part of the Lake district (*q.v.*)—is cut off on the west and south by the Irish sea and Morecambe bay and on the east by the Pennines (*q.v.*). Its northern boundary marches with that of Scotland.

**Physical Features.**—Within this region the Lake mountains form a central mass bounded by the narrow coastal plain and the much greater expanse of the Carlisle plain on the west and north and by the Eden valley to the east. Structurally, the Lake mountains are the relics of a great dome-shaped earth movement of about 40,000,000 years ago. The mountainous area is now deeply dissected by the lake-filled valleys that are disposed in a radial manner about a centre in the Scafell region. The rocks of this region are the oldest in the county, consisting of mudstones of the Skiddaw Slate series and volcanic ashes and lavas of the Borrowdale Volcanic series, all of which have been hardened and altered by pressure to slaty rock types. The Skiddaw slates in the northern zone of the Lake district (Skiddaw, 3,054 ft., and Saddleback, 2,847 ft.) give rise to softer scenery than the tougher volcanic rocks to the south, from which all the principal craggy scenery of the Lake district proper has been formed. Scafell pike (3,210 ft.), Helvellyn (3,118 ft.), Great Gable (2,949 ft.) and the Langdale pikes are the principal mountains of this region. The newer rocks of the district, i.e., the limestones of the Carboniferous system and the sandstones of the New Red series, outcrop in encircling bands around the older slaty rocks. The limestones, which are associated with the later Coal Measure series of the west Cumberland coal field, form the inner band, and the sandstones compose the rocks of the Carlisle plain and the Eden valley. A great thickness of soil (cover consisting principally of heavy clays with local patches of sand and gravel) conceals the solid rock formations, especially in the low-lying areas, where they form the basis of a rich agriculture.

The coastal marshes and mosses are known internationally for their avifauna, and the Drigg Dunes and Gullery Nature reserve near Ravenglass was so designated by the county council in 1954.

J. RUFUS FROM PAUL POPPER

BUTTERMERE, A LAKE OF WEST CUMBERLAND

Long after the Norman conquest, Cumberland remained one of the most densely forested regions of England, and much of the low-lying land is still wooded. The oak, ash and birch are the principal natural trees, while sycamores have been planted for shelter round many farmsteads. Plantations of larch are numerous, and extensive afforestation has been carried out. The National Trust owns the principal peaks and lakes in the Lake District National park.

**History.**—The earliest evidence of man in the area is datable to the New Stone Age, c. 2500 B.C. A settlement site of this period was found at Ehenside tarn, near St. Bees, in 1870, and later a "factory" site, where polished stone axes were wrought from the volcanic rocks, was discovered in Great Langdale. Finds of the subsequent Bronze Age period, especially from coastal and Eden valley localities, give some indication of the passage routes with Ireland to the west and the east Pennine regions to the east. The stone circles, of which Long Meg and her Daughters, near Little Salkeld, and the Castlerigg circle, near Keswick, are the best preserved, are thought to be of this period. The cultural isolation of the region was such that it was still at a Bronze Age level of development at the time of the Roman conquest.

Agricola erected a chain of forts between Solway and Tyne and may have built the Roman naval base at Clanoventa (Ravenglass). About 40 years later, in 122–126, the emperor Hadrian constructed the great wall complex between Wallsend in Northumberland and Bowness-on-Solway, a distance of 73½ mi., and defended the west coast by means of strong forts and signal towers. The Roman occupation was chiefly military in character, with Luguwallium (Carlisle) as the main civil settlement, and Petrianae (Stanwix), the major cavalry headquarters on the wall, on the opposite bank of the Eden.

Christianity came through St. Martin's disciple, St. Ninian (q.v.). He founded Candida Casa (Whithorn) in the year 397 on the north shore of the Solway and several years later, probably, the church at Brampton, within the Roman fort. Re-evangelization came with the defeat of Gwenddoleu ap Ceidio at the battle of Ardderyd in 573 by Rederech, the Christian leader. A century later the district known as Cumbria was in Northumbrian hands, and the famous Bewcastle cross was erected during the period of the Anglian ascendancy. Cumbria was originally the same as Cambria, a Latinized derivative of Cymry or Cymru (Wales). The two names were subsequently differentiated.

The Danes under Halfdan raided Cumbria in 875, but one threat to the northwest was from Ireland or the Isle of Man, the invaders being Norwegian by descent but influenced by their stay among the Celts. Their mark is seen in the inversion compounds of a number of place names, usually on higher ground, e.g., Setmabaning, and in such crosses as that at Gosforth with its mixture of heathen Scandinavian and Christian motives.

In 945 Edmund I ravaged all "Cumbreland" (first mentioned under that name), presumably Strathclyde (q.v.) in its widest sense, handing it over to the Scots king Malcolm I. The earls of Northumbria controlled part of the county in the first half of the 11th century, but by 1068 the area had been taken by the king of Scots and formed no part of William the Conqueror's kingdom, the three manors that appear in Domesday Book being regarded as part of Yorkshire. In 1092 Gospatric II, son of Dolfin, was ruling from Carlisle, under the Scots king, when the city was captured by William II, surnamed Rufus. This king repaired the city, gave orders for the castle to be built and sent settlers to dwell there and till the ground. Immigration from the south about this time is evidenced by the occurrence of place names ending in *by* to which a Norman personal name is prefixed, a number of these being in the neighbourhood of Carlisle. According to Sir William Dugdale's *Baronage of England* (1675–76) the "land of Carlisle," which included parts of Cumberland and the neighbouring county of Westmorland, was granted to Randulf, earl of Chester, styled le Meschin (died c. 1129). Confusion followed the death of Henry I, and the Scots recovered the province, until it was retaken in 1157 by Henry II. The county of Cumberland, as it now exists, dates from 1177. It was divided into five wards, a name peculiar to the English and Scottish borders and corresponding to the hundred (q.v.). Because of its border position Cumberland was the scene of constant strife

until after the union of England and Scotland in 1603.

Edward I, "the hammer of the Scots," died near Carlisle in 1307, when preparing an assault on Scotland, and there was much bloodshed in succeeding centuries. In the Wars of the Roses, England had its own troubles, the prevailing sympathy in Cumberland being with the Lancastrian cause. Carlisle, Cockermouth and Egremont were key points for border defense, but a large number of strong towers were erected along the northern frontier, and Border balladry preserves the records of medieval frays, as well as those of Arthurian legend.

The father of Mary, queen of Scots (James V), died after bearing of the defeat of his army by the English at Solway Moss in 1542, one of his country's worst disasters. Mary's own long journey to her execution at Fotheringay began at Carlisle in 1568. Her son, James, when monarch both of Scotland and England, discovered that Cumbrians were tenacious of their rights, but in the Civil War of the 17th century, along with others in the north, they were loyal to the Stewart cause. The people of Carlisle withstood a siege from Oct. 1644 until June of the following year and regained the town for the king for a few months in 1648. Political feeling would appear to have changed during the reign of James II, and leading men in the county were among the first to welcome William III to England. Active support given to the Stewarts in the risings of 1715 and 1745 was meagre, even if considerable sympathy lingered for them among those who clung to the old faith.

It was after the "45" rebellion of the Jacobites that Cumberland became known to England as a whole. Roads were built or improved, trade was extended and the Lake district, instead of remaining in isolation and known only to the "semiwild inhabitants," became a place to be visited by people of fashion. The mountains and lakes were objects that should be seen and admired, and a mild form of mountaineering was begun. Early in the 19th century William Wordsworth, who was born in Cumberland, and Samuel Taylor Coleridge were leaders of the romantic revival in English poetry. Wordsworth lived at Grasmere and Coleridge settled near Keswick and, with Robert Southey and others, formed a literary group, which had its later counterparts, among others, in Hugh Walpole, O. S. Macdonell, Norman Nicholson and Graham Sutton. The district has its school of painters.

**Historic Buildings.**—Until the death of Elizabeth I in 1603, architectural style was largely determined by the physical nature of the district and by political considerations, especially the need for defense. Materials varied from daub and cobble to sandstone, limestone and the characteristic slate that distinguishes the Keswick neighbourhood, a natural harmony following from the use of native material. The typical Cumberland dwelling is a solid erection, any beauty resting on form and the relationship of solids and voids, carving and other architectural embellishments being rare. The major buildings still occupied in modern times include the castles of Carlisle, Rose, Naworth, Corby, Greystoke and Mun-caster, along with Netherby, Hutton-in-the-Forest and Hutton John. The Norman castles of Cockermouth, Egremont, Millom and the later structure at Penrith are in ruins. Many halls dating from the 17th century, or conversions from earlier peles (or peels) have been or are the homes of armigerous families. The upper story of the pele tower was the solar. Almost all the peles were incorporated into larger buildings; one forms part of the deanery at Carlisle, possibly the most interesting example of domestic architecture in the county. Naworth castle is typical of development from the 14th-century pele to the greater comfort of later ages.

Conventual buildings include the Augustinian priories of Carlisle and Lanercost, the abbeys of Holm Cultram and Calder and the Benedictine priory of St. Bees. These date from the 12th century. The priory of Carlisle (the cathedral), with its wonderful east window, and surviving portions of Lanercost, Holm Cultram and St. Bees are still in use. Parish churches date from the 12th century and vary in size, age and architectural merit; Burgh-by-Sands, Newton Arlosh, Dearham and Great Salkeld were built in the 14th century and are part church and part fortress, their towers being used as places of refuge. Greystoke, which was also a college for priests, and Crosthwaite, for a generation associated with Canon H. D. Rawnsley (1851–1920), one of the founders of the National

trust, are good examples of 15th- and 16th-century work. Robert Southey's tomb is in Crosthwaite church. The small unpretentious fellside churches, Wordsworth's

"Modest house of prayer  
As lowly as the lowliest dwelling"

(from the poem "The Waggoner"), make their own special appeal. Bridges scheduled as ancient monuments include those at Penrith across the Eamont (1425) and at Lanercost over the Irthing (1533, rebuilt 1724). The bridge at Penrith was saved through the efforts of Canon Rawnsley. The present Eden crossings at Carlisle and Kirkoswald replaced earlier buildings. Old pack-horse bridges exist in many parts of the county.

**Industries.**—About half of the total area of the county is under cultivation, and more than one-third is in rough grazings. Stock farming, especially for sheep, is the main rural occupation, though cattle are important; the number of sheep is about three times that of cattle. The principal arable crop is oats, followed by turnips, swedes, beets and potatoes. Herdwick and Swaledale fell sheep are favoured in the hills, and draft ewes are crossed with larger ones in the lowlands.

The industries of Cumberland have been from earliest times connected with its fisheries and mineral wealth. The lead and silver mines of Alston and the iron mines near Egremont have been worked since the 12th century. Those in the neighbourhood of Keswick, of copper, lead and silver, were a major industry during part of the 16th century and, though worked intermittently thereafter, closed down in 1927; development in the early years at both places was the result of German enterprise. Coal has been worked in both the east and west of Cumberland since the middle ages on a developing scale, but an output of 2,000,000 tons annually of saleable coal in the west was not reached after 1929, and haulage difficulties there have added greatly to the cost of production. For economic reasons the mines in the east of the county were closed in 1953. Near Whitehaven, methane gas, the possibilities of which were first shown there in the 1760s, is in use for industrial purposes, and new coal fields were open near Maryport, close to the Scottish border on the northwest. In the early 1960s the known iron-ore reserves, about 7,000,000 tons, were at Ullcoats and Florence, Beckermat and Hodbarrow and served the west Cumberland blast furnaces, which required 1,100,000 tons of haematite iron ore annually for the production of 600,000 tons of pig iron and iron alloys. The chief supplies of ore come from Spain and north Africa. Non-ferrous metals occur but not in sufficient quantity to justify exploitation. Important developments have taken place in the mining of anhydrite (gypsum without water of crystallization), used in the manufacture of sulfuric acid and ammonium sulfate. The Solway mine, at Sandwith, near Whitehaven, was opened in 1955; it was designed to produce 7,000 tons per week and to absorb much of the ore locally as acid, with cement as a by-product. The Long Meg mine, near the druid circle of that name, has a potential annual output of 250,000 tons. Gypsum, an associated mineral, is mined on a considerable scale at Lazonby and Cocklakes, and granite, slate and limestone are extensively quarried. Textiles, haulage machinery, metal containers and biscuits are manufactured at Carlisle. Sellafield on the coastal plain was the site chosen for the development of Great Britain's atomic energy industry. In 1947 work was begun on the Windscale works, the first plant in the country to produce plutonium, and its two chimneys, each 412 ft. high, are a well-known Cumberland landmark. Nearby, at Calder Hall, on the other side of the river Calder, the first atomic power station in Great Britain was opened by Queen Elizabeth II in 1956. The later construction of three more thermal reactors brought the total capacity of the station to 184,000 kw., 150,000 of which was fed into the national electricity grid. By the early 1960s an advanced gas-cooled reactor with an electrical generating capacity of 28,000 kw. was also in operation. John Dalton (1766-1844), chemist and natural philosopher who pioneered the concept of the atomic theory, was born nearby at Eaglesfield.

The Eden, Derwent (*qq.v.*) and Esk rivers are famed for their salmon.

The chief ports are Workington, Whitehaven, Maryport and Silloth. Main railway lines from the south enter the county at

Penrith and Culgaith, with Carlisle as the focus. This is the western route to Scotland.

Cumberland is probably unexcelled in England for scenic beauty and attracts many visitors. The tourist centre of the county is a "pocket Switzerland," with the Keswick (*q.v.*) neighbourhood as the chief attraction.

**Population and Administration.**—The area of the administrative county (which excludes Carlisle county borough) is 1,511.5 sq.mi., with a population of 223,050 in 1961. The county contains two boroughs, Workington (pop. [1961] 29,507) and Whitehaven (27,541); four urban district councils, Cockermouth, Keswick, Penrith and Maryport; and seven rural district councils. The county town is the city of Carlisle (71,112), a county borough. Cumberland is in the northern circuit, and assizes are held at Carlisle. It has a court of quarter sessions and 12 petty sessional divisions. Carlisle has a separate commission of the peace and court of quarter sessions. It returns one member to parliament, and three others are returned, respectively, by the Penrith and the Border, Whitehaven and Workington divisions of the county.

In 685 Carlisle and district were annexed by Egfrith of Northumbria to the diocese of Lindisfarne, to which it continued subject until the Danish invasion of the 9th century. In 1133 Henry I created Carlisle a bishopric. In 1856 the diocese was extended to include the whole of Cumberland except the parish of Alston (in the diocese of Newcastle), the whole of Westmorland and the Furness district of Lancashire. The parish of Firbank, in Westmorland, is in the diocese of Bradford.

**CUMBERLAND**, the third largest city of Maryland, U.S., on the Potomac river, in the northwestern part of the state; seat of Allegany county. The city is 635 ft. above sea level and is surrounded on three sides by mountain scenery. A deep gorge of great beauty, the Narrows, forms a natural gateway through the Appalachian mountains west to the Ohio valley. Cumberland was the eastern terminus of the Cumberland (or National) road and the western terminus of the Chesapeake and Ohio canal. It has a large trade in coal, of which the county mines about 1,500,000 tons a year. Manufactures include plastics, rubber tires, glassware, firebrick, lumber products and beer. The railroad shops repair and build all types of equipment. Cumberland is a retail and wholesale centre for western Maryland, large sections of West Virginia and Pennsylvania. The first settlement was made in 1750, and in 1754 Col. James Imes built Ft. Cumberland at Wills creek as a defense against the French and their Indian allies. From this fort Gen. Edward Braddock started on his disastrous expedition of July 9, 1755. A town was laid out in 1763 and incorporated in 1815. In 1850, when the population was 6,073, it was chartered as a city. For comparative population figures see table in MARYLAND: *Population*.

(R. M. LA.)

**CUMBERLAND PLATEAU**, the westernmost of the three great divisions of the Appalachian highlands in the U.S., extends from West Virginia to northern Alabama. Its steep eastern escarpment, known as the Allegheny front, separates the plateau from the Appalachian Ridge and Valley region. Its dissected west-northwestern boundary faces the rolling, limestone-based plains of central Kentucky, Tennessee and southern Ohio. The plateau surface merges with the unconsolidated sediments of the Gulf coastal plain west of Birmingham, Ala. From southern West Virginia northward the plateau is known as the Allegheny plateau. Ap-

proximately 450 mi. in length and from 40 to 50 mi. in width, the plateau surface rolls extensively and slopes gently westward. The surface consists of coarse sandstones overlain by thin, sandy, relatively infertile soils.

The roughest, highest, most dissected portion of the plateau, a narrow linear ridge about 140 mi. in length, forms its eastern margin in eastern Kentucky and northeastern Tennessee; the name Cumberland mountains generally is applied to this area. This ridge varies in elevation from about 2,000 to 4,145 ft. at Big Black mountain, Kentucky. Sequatchie valley, an anticline uncovered by erosion, separates Walden ridge from the main plateau surface northwest of Chattanooga. Lookout mountain, situated in southern Tennessee, northwestern Georgia and northeastern Alabama, is separated from Walden ridge at Chattanooga by the incised, steep-sided valley of the Tennessee river. Headwaters of the Tennessee, Kentucky and Cumberland rivers rise in the central segment of the plateau.

The plateau is underlain by large deposits of coal, limestones used for cement, and fine-grained sandstones suitable for construction and decorative purposes. Forests, a major resource, composed mainly of hardwoods, occupy more than three-fourths of the plateau area. Sand mountain, in northern Alabama, is the only segment of the plateau characterized by a well-developed agriculture.

Cumberland gap (elevation *c.* 1,650 ft.), situated near the point where Virginia, Tennessee and Kentucky meet, is a structural fault which provides a natural passage through the Cumberland mountains. It was discovered in 1750 by Thomas Walker; Daniel Boone's Wilderness road to Kentucky ran through it. Because of its strategic importance, it was held alternately by Confederate forces (1861; 1861-63) and Union troops (1861; 1863-65) during the American Civil War. (M. C. P.)

**CUMBERLAND RIVER**, a large southern branch of the Ohio river, U.S., rises in the Cumberland mountain region of the Cumberland plateau in Harlan and Letcher counties in extreme southeastern Kentucky. After a devious course of 687 mi. in Kentucky and Tennessee the Cumberland reaches the Ohio at Smithland, Ky., 12 mi. upstream from the mouth of the Tennessee (*q.v.*). Three principal headwater streams unite at Harlan, Ky., to form the Cumberland river proper. From its headwaters through Harlan and to Cumberland falls, a natural drop of 63 ft. in Whitley county, Ky., and site of a state park, the river is a mountain stream of little volume during late summer and subject to disastrous floods during winter and spring.

The portion of the Cumberland from Williamsburg, above the falls, past the falls and to the Kentucky-Tennessee state line crosses a highland bench in the Cumberland plateau and flows in a gorge between precipitous cliffs 300-400 ft. in height. Thence the river enters the central limestone basin of Tennessee and finally turns northward and crosses the plain of western Kentucky to the Ohio. At one point the river is less than two miles from the lower Tennessee. Chief tributaries, all entering downstream from the falls, are the Laurel, Rockcastle and South Fork in Kentucky; the Obey, Caney Fork, Stones, Harpeth and Red in Tennessee; and the Little river in western Kentucky.

Nashville, Tenn., is the only large city on the river. Smaller cities are Pineville, Barbourville and Williamsburg in eastern Kentucky; Carthage, Clarksville and Dover in Tennessee; and Eddyville in western Kentucky. Middlesboro, Ky., at the northern slope of Cumberland gap, is on an upstream headwater.

Development of a series of lakes on the Cumberland comparable to those on the Tennessee (Tennessee Valley authority) was planned by the U.S. army corps of engineers. Dams, both existing and authorized, will control the mountain headstreams. Wolf Creek dam, for flood control and power, in Russell county, Ky., created Lake Cumberland, which extends to the base of Cumberland falls. Large power dams are in operation on two tributaries: Dale Hollow dam on the Obey near Celina, Tenn., and Center Hill dam on Caney Fork southeast of Carthage. The dams on the lower river are power and navigation dams and contain locks. Old Hickory dam, upstream from Nashville, ponds the water to Carthage, the head of navigation. Cheatham dam is upstream

from Clarksville. Barkley dam was placed in operation in 1966 to control the lower river, with its reservoir submerging five smaller dams and their locks, and connect with the lower Tennessee.

During the Civil War, Fort Donelson on the Cumberland was captured by Gen. U. S. Grant—a decisive event of the war.

(L. D.)

**CUMBERNAULD**, a New Town in the detached part of Dunbartonshire, Scot., between Stirlingshire and Lanarkshire, lying 14 mi. N.E. of Glasgow by road. Formed in 1956 and designated to accommodate overspill population from Glasgow, this New Town of 18.5 sq.mi. had a population of 4,924 in 1961; the estimated eventual population was 70,000. (See New Towns.)

At Cumbernauld the main Glasgow-Stirling road joins the road to Airdrie and the south, and the town is also on the Forth and Clyde canal and on the main railway line from Edinburgh to Glasgow. The area, which is hilly, is rural and agricultural, the only former industries being a brickwork and two grain mills. The first new factory was for making adding machines.

**CUMBRAES, THE**, two islands forming a parish and part of Buteshire, Scot., lie in the Firth of Clyde between the southern shores of Bute and the coast of Ayrshire. In 1961 the population of the two islands was 1,646, concentrated almost entirely in Millport (1,593), on Great Cumbrae.

Great Cumbrae island, about 1½ mi. W.S.W. of Largs, is 1.9 mi. long and 3.7 mi. broad and has an area of 4.4 sq.mi. Of Old Red Sandstone, its elevation is 415 ft. above sea level. The island is well farmed and there is some fishing. The burgh of Millport, which is primarily a holiday resort, is well situated at the head of a fine, sandy bay with a climate that is both warm and bracing. It has steamer connections with Wemyss Bay, Largs and Fairlie. There are excellent facilities for bathing, boating and fishing, together with a golf course, tennis courts and bowling greens. Among the chief buildings are the Episcopalian cathedral, erected in Gothic style on rising ground behind the town, the college connected with it (not now used as such), a marine biological station with an aquarium, and Garrison house, now used as the municipal headquarters. The cathedral, originally the collegiate church, was founded in 1849 by the earl of Glasgow and constituted the cathedral of Argyll and the Isles in 1876.

Little Cumbrae island lies to the south, separated by the Tan, a strait half a mile wide. It is 1.9 mi. long and barely 1 mi. broad and has an area of 1.1 sq.mi. Pop. (1961) 8. Its highest point is 409 ft. above sea level and on the bold cliffs of the west coast stands a lighthouse. On an islet off the eastern shore Robert II is said to have occupied a castle, which was demolished by Cromwell's soldiers in 1653; the remains of the tower can be seen.

See R. A. Downie, *Bute and the Cumbraes* (1934). (A. H. Wd.)

**CUMIN** or **CUMMIN** (*Cuminum cyminum*) is a small, slender annual herb of the family Umbelliferae, with finely dissected leaves, white or rose coloured flowers, and grayish, bristly fruits about one-fourth inch long, tapering toward both ends and laterally compressed. It is apparently native to the Mediterranean region where it is extensively cultivated, as it is also in India, China and Mexico.

Cumin seeds have an aromatic odour, a spicy somewhat bitter taste and are widely used as condiment. They are employed as an essential component in all mixed spices and curry powders, for flavouring cheese, sausages, soups and pickles, and for seasoning breads and cakes. Cumin seeds were at one time widely used as home medicinals but they are now chiefly used in veterinary medicine. The seeds yield on distillation a volatile oil which has the odour and taste of the whole seeds. The oil is used in perfumery, for flavouring liquors and cordials and medicinally as a stomachic and carminative. (Q. J.)

**CUMMINGS, BRUCE FREDERICK:** see BARBELLON, W. N. P.

**CUMMINGS, EDWARD ESTLIN** (1894-1962), U.S. poet and artist, whose poetry is marked by typographical nonconformity and by stylistic originality and experiment (and who signed his name as "e. e. cummings"). He was born in Cambridge, Mass., on Oct. 14, 1894, and received his B.A. degree from Harvard university in 1915, his M.A. in 1916. During World War I, he served

with an ambulance corps in France, where, because of a military error, he was interned for a time in a detention camp, an experience recorded in his first book, the prose work *The Enormous Room* (1922). Later he served as a private in the U.S. army at Camp Devens, Mass.

He began writing poetry at Harvard and after the war devoted himself wholly to writing and painting. His first book of verse was *Tulips and Chimneys* (1923), followed by *XLI Poems* (1925) and *&* (1926); in 1926 he received the Dial award. He then began also to exhibit his paintings and drawings. In 1927 his first play, *Him*, was produced by the Provincetown Players in New York; he later wrote other poetic dramas, including *Tom* (1935) and *Santa Claus: A Morality* (1946). Among many volumes of verse were: *Is 5* (1926), *ViVa* (1931), *No Thanks* (1935), *Collected Poems* (1938), *One Times One* (1944), *Poems 1923-1954* (1954) and *95 Poems* (1958). His experimental prose book, *Eimi* (1933), recorded his trip to Russia and his reaction to communist society. In 1953 he published his discussions as Charles Eliot Norton lecturer on poetry at Harvard (1952-53) as *i: six nonlectures*. In 1957 he received both the Bollingen prize for poetry and the Boston Arts Festival award. After 1920 he lived in New York city and on a farm in the White mountains near North Conway, N.H., where he died on Sept. 3, 1962.

See Charles Norman, *The Magic Maker: E. E. Cummings* (1958).

**CUMMINS, ALBERT BAIRD** (1850-1926), U.S. lawyer, state governor and U.S. senator, was born at Carmichaels, Greene county, Pa., Feb. 15, 1850 and educated at Waynesburg (Pa.) college. He studied surveying, worked in railroad construction and then studied law in Chicago, practising there for three years. In 1878 he moved to Des Moines, Ia., and soon became the leading lawyer in that city, winning fame as counsel for the Iowa Grange in its suit to break up the "barbed wire" trust. Professional life was soon mixed with politics, which he pursued with vaulting ambition. Beginning in the Iowa house of representatives in 1888, he served the Republicans as state central committee chairman, 1892-96; member of the national committee, 1896-1900; and four times as delegate to national conventions. He tried for the U.S. senate in 1894 and 1900 but failed. Between 1902 and 1908 he was elected governor three terms in succession and became the recognized spokesman for the progressive Republicans in Iowa. These progressives owed nothing to Populism; the leaders were successful, often wealthy, urban businessmen who wanted political power and a new moral tone in Iowa government. Cummins' three terms brought further regulation of the railroads, abolition of the free pass system and enactment of a senatorial primary law.

In 1907-08 he precipitated a political war by running against the aged William B. Allison for the Republican senatorial nomination and lost by 10,000 votes. Allison died just two months later and Cummins was soon seated in his place. Sen. Jonathan P. Dolliver, who had managed Allison's campaign, quickly accepted Cummins and the two made a strong team of progressive senators against the archconservative Sen. Nelson W. Aldrich. Cummins opposed President Wilson on the arming of merchantmen in 1917 and on the treaty of Versailles. In 1920 the Esch-Cummins act provided for the return of the railroads to private control—after their government operation during the war—but did not include Cummins' plan for consolidation of the roads into a few national, truly competitive companies. His last years were embittered by the rebellion of his erstwhile lieutenant, Smith W. Brookhart, who defeated him in 1926. Cummins died of a heart attack two months later, July 30, 1926, at Des Moines. (L. L. S.)

**CUMMINS, GEORGE DAVID** (1822-1876), U.S. clergyman, first bishop of the Reformed Episcopal Church, was born near Smyrna, Del., on Dec. 11, 1822, of Scotch-English ancestry. His father was an Episcopalian, his mother a Methodist. After graduating from Dickinson college (Carlisle, Pa.), on July 8, 1841, he served three years as a licentiate in charge of Bladensburg (Md.) circuit of the Methodist Episcopal Church before deciding to study for the ministry of the Protestant Episcopal Church. He was ordained by Bishop Alfred Lee of Delaware on Oct. 26, 1845. Cummins gained early recognition as a distinguished preacher and served a succession of important parishes in Norfolk, Richmond,

Washington, Baltimore and Chicago. He married Alexandrine Macomb Balch on June 24, 1847. Elected assistant bishop of Kentucky in 1866, he soon found himself, as a recognized younger leader of the Evangelicals, in the midst of the ritualistic controversy which reached its peak in the Protestant Episcopal Church in the years following the Civil War. As early as 1869, he began to receive appeals from some who, despairing of the future of Evangelicalism within the Protestant Episcopal Church, wanted him to take the lead in organizing a new body. Though deeply disappointed by the failure of Evangelical measures in the General convention of 1871, Cummins did not finally decide on a break until 1873. The Reformed Episcopal Church was organized in New York on Dec. 2, 1873, with Cummins as its only bishop, though a second, Charles Edward Cheney (q.v.), was soon consecrated. Cummins died at Lutherville, Md., on June 26, 1876. For portrait see article PROTESTANT EPISCOPAL CHURCH. (W. W. Ms.)

**CUMNOCK AND HOLMHEAD**, a police burgh of Ayrshire, Scot., in the parish of Old Cumnock. It lies on the Lugar water, 26 mi. S. of Glasgow (36 mi. by road) and about 360 ft. above sea level. Pop. (1961) 5,403. Holmhead is part of the parish of Auchinleck but is joined to Cumnock for administrative purposes. A considerable proportion of the population depends on coal mining, there being more than 30 pits or mines within 10 mi. of Cumnock. It is also an agricultural centre with a large wool-spinning mill. The civil parish of New Cumnock lies 5 mi. S.E. at the confluence of Afton water and the Nith. New Cumnock is a mining parish and was separated from Cumnock in 1650. Auchinleck, 2 mi. N.W., is the seat of the Boswell family. Auchinleck house, built by Lord Auchinleck, father of James Boswell, was visited in 1773 by Samuel Johnson. Boswell is buried in the church. Alexander Peden, the persecuted Covenanter known for his prophecies, was also buried in the church (1686), but his body was exhumed by a company of dragoons 40 days after the burial and reinterred at the foot of the gallows at Cumnock. After the revolution of 1689 the inhabitants, out of respect for the "prophet's" memory, abandoned their old burying ground and made a new one round the gallows' hill. A monument was erected to Peden's memory. James Keir Hardie (1856-1915), the Labour leader, made his home in Cumnock.

**CUMONT, FRANZ VALÉRY MARIE** (1868-1947), Belgian historian of religion, was born on Jan. 3, 1868, at Alost. After studying at Ghent, Bonn, Berlin, Vienna and Paris, he was from 1892 to 1910 professor in Ghent university, and from 1899 to 1912 curator of the Brussels Royal museum. Cumont's chief writings deal with Mithraism, Manichaeism, Roman paganism and other aspects of ancient religion.

He died Aug. 25, 1947, at Brussels.

**CUNA**, a tribe of Chibchan-speaking Indians who occupied the central region of Panamá and the neighbouring San Blas islands and who still survive in marginal areas. In the 16th century they were an important group, living in federated villages under chiefs having considerable power, and engaging in warfare with each other and with neighbouring tribes. Agriculture was primarily based on slash-and-burn techniques, and there was extensive trade, mainly by canoe along the coast. There was a well-developed class system, with captives generally being enslaved. Important chiefs were carried in hammocks. Their bodies were preserved after death and buried in large graves with their wives and retainers.

The important excavations in the Coclé region present additional information on the Cuna and their neighbours in the late prehistoric period. Metallurgy was well developed and numerous gold ornaments have been found in the graves, along with fine ceramics and shell ornaments.

The principal effects of European contact were to destroy the political superstructure of the Cuna and to modify the social and religious system. In modern times they live in small villages and depend primarily on agriculture for subsistence, supplemented by fishing and hunting. Marriage is matrilineal, giving rise to extended families in which the son-in-law is under the authority of his wife's father. Religion centres around shamanism, which is highly developed. The sun and moon were formerly major deities and the world is thought to be composed of multiple layers; the my-

thology has been much affected by European conceptions. The so-called "white Indians" of San Blas are actually albinos who comprise about 0.7% of the Cuna population and are not permitted to intermarry.

**CUNARD, SIR SAMUEL, BART.**, (1787–1865), British merchant and shipowner, founder of the first regular Atlantic steamship line, was born at Halifax, N.S., Canada, on Nov. 21, 1787. In partnership with George Burns, David MacIver and other prominent merchants of Glasgow and Liverpool, he formed a company to carry out the British government's proposal to substitute steamships for sailing vessels in the transatlantic mail service.

Cunard was created a baronet in 1859. He died on April 28, 1865.

**CUNAXA, BATTLE OF.** This battle, fought in 401 B.C. on a site north of Babylon, in which Cyrus the Younger (*see* CYRUS) was defeated by his brother Artaxerxes II and killed, was followed by the "Retreat of the Ten Thousand" under Xenophon (*q.v.*). Cyrus had surreptitiously increased his forces and marched inland from Sardis against Artaxerxes. The two armies met unexpectedly at Cunaxa, on the left bank of the Euphrates river. The Greek mercenaries under Clearchus, nearly 13,000 strong and the best trained and equipped troops in Cyrus' army, were stationed on the right wing near the river, supported by about 1,000 Paphlagonian cavalry. Artaxerxes' right extended beyond Cyrus' left. Cyrus ordered Clearchus to advance obliquely against Artaxerxes' centre, as the king himself was there. Clearchus, however, was unwilling to expose his flank by leaving the river. In the battle, Persian cavalry charged harmlessly through the Greek light-armed by the river, and the Greek heavy-armed routed the Persian left with few casualties. Cyrus charged Artaxerxes' centre with 600 cavalry and succeeded in wounding his brother, but was killed. The Greeks returned from pursuing the Persian left to find that the rest of Cyrus' troops had been routed and his camp plundered. By forming ranks again, they discouraged Artaxerxes from attacking them and despite the subsequent capture and murder of their leaders by the satrap Tissaphernes succeeded in marching through hostile country to the Black sea.

**CUNDINAMARCA**, most populous of the departments of the republic of Colombia. Area 8,934 sq.mi.; pop. (1961) 2,071,260, including the Special District of Bogotá. A considerable part of its area consists of old inter-Andean lake surfaces or *sabanas* from 8,000 to 9,000 ft. above sea level that were lakes during the Pleistocene. These *sabanas* have a temperate to cool climate and their fertile but poorly drained soils support fine herds of blooded European dairy cattle and produce many of the fruits and cereals of more northerly latitudes. Another important part of Cundinamarca lies in the hot, dry valley of the Magdalena. The slopes between these two regions are densely settled, being especially celebrated for their coffee plantations.

Cundinamarca, and especially the *sabana* of Bogotá, was one of the centres of the Chibcha empire. It was on the plains of Bogotá (elev. 8,600 ft.) that the three conquistadores, Gonzalo Jiménez de Quesada, Nikolaus Federmann and Sebastián de Belalcázar (Sebastián Moyano), met accidentally in 1538. Santa Fé de Bogotá, founded in that year by Quesada, from the start was the most important city in the viceroyalty of New Granada, later to become Colombia.

Bogotá (*q.v.*) has remained the economic, cultural and political capital of Colombia despite its inaccessible interior location. In 1955 it was separated from Cundinamarca as a Special District (*Distrito Especial*) for administrative purposes, though at the same time remaining the capital of Cundinamarca.

Other important cities are Girardot, Fusagasugá and Facatativá. Zipaquirá, 30 mi. north of Bogotá, is famed for its underground salt mines. An important tourist attraction is the 300-ft.-high Tequendama falls where the Río Bogotá leaves the high *sabana*

surfaces. Lake Guatavita is celebrated for the legend of Eldorado (*q.v.*) or the gilded man. *See* also COLOMBIA. (Js. J. P.)

**CUNEIFORM**, a Latin coinage meaning "wedge-shaped" (in German *Keilschrift*), has been the modern designation, from the early 18th century onward, for the most widespread and historically significant writing system in the ancient near east. Its active history comprises the last three millennia B.C.; its long development and geographic expansion involve numerous successive cultures and languages; and its over-all significance as an international graphic medium of civilization is second only to that of the Phoenician-Greek-Latin alphabet. (*See* also BABYLONIA AND ASSYRIA; ALPHABET.)

**Origin and Character.**—The origins of cuneiform may be traced back approximately to the end of the 4th millennium B.C. At that time the Sumerians, a people of unknown ethnic and linguistic affinities, inhabited southern Mesopotamia and the region west of the mouth of the Euphrates known as Chaldea. While it does not follow that they were the earliest inhabitants of the region or the true originators of their system of writing, it is to them the first attested traces of cuneiform writing are conclusively assigned. Excavations of remote prehistoric strata at the ancient sites of Ur and Uruk have failed to reveal decisive evidence of preceding populations. The earliest written records in the Sumerian language (*q.v.*) are pictographic tablets from Uruk, evidently lists or ledgers of commodities identified by drawings of the objects, and accompanied by numerals (*see* NUMERALS AND NUMERAL SYSTEMS) and personal names. Such word writing was able to express only the basic ideas of concrete objects. Numerical notions were easily rendered by the repetitional use of strokes or circles. However, the representation of proper names, for example, necessitated an early recourse to the rebus principle; i.e., the use of pictographic shapes to evoke in the reader's mind an underlying sound form rather than the basic notion of the drawn object. This brought about a transition from pure word writing to a partial phonetic script. Thus, for example, the picture of a hand came to stand not only for Sumerian *šu* ("hand"), but for the phonetic syllable *šu* in any required context. Sumerian words were largely monosyllabic, so the signs generally denoted syllables, and the resulting mixture is termed a word-syllabic script. The inventory of phonetic symbols henceforth enabled the Sumerians to denote grammatical elements by phonetic complements added to the word signs (the latter are called ideograms or logograms; *see* LOGOGRAM AND SYLLABARY). Because Sumerian had many identical sounding (homophonous) words, several ideograms frequently yielded identical phonetic values, and are distinguished in modern transliteration as; e.g., *ba*, *bá*, *bò*, *ba*. Because an ideogram often represented several related notions with different names (e.g., "sun," "day," "bright"), it was capable of assuming more than one phonetic value (this feature is called polyphony).

In the course of the 3rd millennium the writing became successively more cursive, and the pictographs developed into conventionalized linear drawings. Due to the prevalent use of clay tablets as writing material (stone, metal or wood also were employed occasionally), the linear strokes acquired a wedge-shaped appearance by being pressed into the soft clay with the slanted edge of a stylus. Curving lines disappeared from writing, and the normal order of signs was fixed as running from left to right, without any word-divider. This change from earlier columns running downward entailed turning the signs on one side.

**Spread and Development.**—Before these developments had been completed, the Sumerian writing system was adopted by the Akkadians. Semitic invaders who established themselves in Mesopotamia about the middle of the 3rd millennium. In adapting the script to their wholly different language the Akkadians retained the Sumerian ideograms and combinations of ideograms for more complex notions, but pronounced them as the corresponding Akkadian words. They also kept the phonetic values, but extended them far beyond the original Sumerian inventory of simple types (open or closed syllables like *ba* or *ab*). Many more complex syllabic values of Sumerian ideograms (of the type *kan*, *mul*, *bat*) were transferred to the phonetic level, and polyphony became an increasingly serious complication in Akkadian cuneiform (e.g., the

original pictograph for "sun" may be read phonetically as *ud, tam, th, par, lah, his*). The Akkadian readings of the ideograms added new complicated values. Thus the sign for "land" or "mountain range" (originally a picture of three mountain tops) has the phonetic value *kur* on the basis of Sumerian, but also *mat* and *šad* from Akkadian *mātu* ("land") and *šadū* ("mountain"). No effort was made until very late to alleviate the resulting confusion, and equivalent "graphies" like *ta-am* and *tam* continued to exist side by side throughout the long history of Akkadian cuneiform.

The earliest type of Semitic cuneiform in Mesopotamia is called the Old Akkadian, seen for example in the inscriptions of the great ruler Sargon of Akkad (c. 2350 B.C.). Sumer, the southernmost part of the country, continued to be a loose agglomeration of independent city-states, until it was united by Gudea of Lagash (c. 2050 B.C.), in a last brief manifestation of specifically Sumerian culture. The political hegemony then passed decisively to the Akkadians, and King Hammurabi of Babylon (c. 1700 B.C.) unified all of southern Mesopotamia. Babylonia thus became the great and influential centre of Mesopotamian culture. The Code of Hammurabi is written in Old Babylonian cuneiform, which developed throughout the shifting and less brilliant later eras of Babylonian history into Middle and New Babylonian types. Farther north in Mesopotamia the beginnings of Assur were more humble. Specifically Old Assyrian cuneiform is attested mostly in the records of Assyrian trading colonists in central Asia Minor (c. 1950 B.C.; the so-called Cappadocian tablets) and Middle Assyrian in an extensive Law Code and other documents. The New Assyrian period was the great era of Assyrian power, and the writing culminates in the extensive records from the library of

Assurbanipal at Nineveh (c. 650 B.C.).

The expansion of cuneiform writing outside Mesopotamia began in the 3rd millennium, when the country of Elam in southwestern Iran was in contact with Mesopotamian culture and adopted the system of writing. The Elamite sideline of cuneiform continued far into the 1st millennium B.C., when it presumably provided the Indo-European Persians with the external model for creating a new simplified quasi-alphabetic cuneiform writing for the Old Persian language.

The Hurrians in northern Mesopotamia and around the upper stretches of the Euphrates adopted Old Akkadian cuneiform around 2000 B.C. and passed it on to the Indo-European Hittites, who had invaded central Asia Minor at about that time.

In the 2nd millennium the Akkadian of Babylonia, frequently in somewhat distorted and barbarous varieties, became a *lingua franca* of international intercourse in the entire near east, and cuneiform writing thus a universal medium of written communication. The political correspondence of the era is conducted almost exclusively in that language and writing. Cuneiform was sometimes adapted, as in the consonantal script of the Canaanite city of Ugarit on the Syrian coast (c. 1400 B.C.), or simply taken over, as in the inscriptions of the kingdom of Haldi or Urartu in the Armenian mountains from the 9th to 6th centuries B.C.; the language is remotely related to Hurrian, and the script a borrowed variety of New Assyrian cuneiform. Even after the fall of the Assyrian and Babylonian kingdoms in the 7th and 6th centuries B.C., when Aramaic had become the general popular language, rather decadent varieties of Late Babylonian and Assyrian survived as written languages in cuneiform almost down to the time of Christ. See also AKKADIAN LANGUAGE.

#### DECIPHERMENT

Many of the cultures employing cuneiform (Hurrian, Hittite, Haldian) disappeared one by one, and their written records fell into oblivion. The same fate overtook cuneiform generally with astonishing swiftness and completeness. One of the reasons was the victorious progress of the Phoenician script in the western sections of the near east and the classical lands in Mediterranean Europe. To this writing system of superior efficiency and economy cuneiform could not offer serious competition. Its international prestige of the 2nd millennium had been exhausted by 500 B.C., and Mesopotamia had become a Persian dependency. Late Babylonian and Assyrian were little but moribund artificial literary idioms. Unlike the hieroglyphs (*q.v.*) of Egypt, which served continuously for more than three millenniums as an aesthetically refined ornamental medium on the monuments of an almost monolithic culture, cuneiform was essentially a practical everyday writing, tied to the vicissitudes and uncertainties of changing civilizations. So effective was its disappearance in the sands of the near east that the classical Greeks were practically unaware of its existence, except for the widely traveled Herodotus who in passing mentions *Assyria Grammata* ("Assyrian characters").

**Old Persian and Elamite.**—The rediscovery of the materials and the reconquest of the recondite scripts and languages have been the achievement of modern times. Paradoxically the process began with the last secondary offshoot of cuneiform proper, the inscriptions (*q.v.*) of the Achaemenid kings (6th to 4th centuries B.C.) of Persia. (See PERSIAN HISTORY.) This is understandable, because almost only among the Persians was cuneiform used primarily for monumental writing, and the remains (such as rock carvings) were in many cases readily accessible. Scattered examples of Old Persian inscriptions were reported back to Europe by western travelers in Persia since the 17th century, and the name cuneiform was first applied to the script by Engelbert Kämpfer (c. 1700). During the 18th century many new inscriptions were reported; especially important were those copied by Carsten Niebuhr at the old capital Persepolis. It was recognized that the typical royal inscriptions contained three different scripts, a simple type with about 40 different signs, and two others with considerably greater variations. The first was likely to reflect an alphabet, while the others seemed to be syllabaries or word writings. Assuming identical contents in three different languages,

scholars argued on historical grounds that those trilingual inscriptions belonged to the Achaemenid kings, and that the first writing represented the Old Persian language which would be closely related to Avestan and Sanskrit. The recognition of a diagonal wedge as word-divider simplified the segmentation of the written sequences. The German scholar Georg Friedrich Grotefend (*q.v.*) in 1802 reasoned that the introductory lines of the text were likely to contain the name, titles, and genealogy of the ruler, the pattern for which was known from later Middle Iranian inscriptions in an adapted Aramaic (*s.e.*, ultimately Phoenician) alphabet. To a repetitive sequence he assigned the meaning "king of kings," and he also isolated the word for "son." The genealogy of Achaemenid rulers was known from Herodotus, and the available names could now be tested in appropriate places in the text. Grotefend found that the author of one inscription was identical with the father of the ruler in another; this father was also styled "king," while his own father in the former inscription was not. Thus it was ingeniously deduced that the kings must be Darius and his son Xerxes, because the father of Darius, Hystaspes, was not king (the preceding rulers, Cyrus and Cambyses, belonged to a different branch of the Achaemenid dynasty). This enabled the several long proper names to be read and a number of sound values to be determined. The initial results of Grotefend were expanded and refined by other scholars. Henry Rawlinson published in 1846 the great Behistun inscription of Darius, which enabled him to delve deeper into the language and to establish its close affinity with Avestan and Sanskrit.

Next the second script of the trilinguals was attacked. It contained over 100 different signs and was thus likely to be a syllabary. Mainly by applying the sound values of the Old Persian proper names to appropriate correspondences a number of signs were gradually determined, and some insight gained into the language itself, which is New Elamite; the study of it has been rather stagnant, and considerable obscurity persists. The same holds true for the Old Elamite of the late 2nd millennium.

**Akkadian and Sumerian.**—The third script of the Achaemenian trilinguals had in the meantime been identified with that of the texts found in very large numbers in Mesopotamia, which obviously contained the central language of cuneiform culture, namely Akkadian. Here also the proper names provided the first concrete clues for a decipherment, but the extreme variety of signs and the peculiar complications of the system raised difficulties which for a time seemed insurmountable. The serious external divergencies between older and newer types of Akkadian cuneiform, the distribution of ideographic and syllabic uses of the signs, the simple (*ba, ab*) and complex (*bat*) values of the syllables, and especially the bewildering polyphony of many notations were only gradually surmised by scholars like Rawlinson, Edward Hincks (by the use of frequency counts), Fox Talbot and Jules Oppert. Once the Semitic character of the language had been established, the philological science of Assyriology developed rapidly from the closing decades of the 19th century onward, especially because of scholars like Friedrich Delitzsch, and in more recent years Benno Landsberger and Wolfram von Soden. (See SEMITIC LANGUAGES.)

Once Akkadian had been deciphered, the very core of the system was intelligible, and the prototype was provided for the interpreta-

BY COURTESY OF ORIENTAL INSTITUTE  
PERSIAN CUNEIFORM FROM THE  
XERXES INSCRIPTION AT PERSEPOLIS

tion of other languages in cuneiform. Until the 20th century Sumerian was not definitely recognized as a separate language at all, but rather as a special way of noting Akkadian. Even when its independent character was established, the difficulties of interpretation were appalling, because of its strange and unrelated structure. After Sumerian finally died out as a living language toward the middle of the 2nd millennium, it lingered on as a cult idiom of Babylonian religion. To facilitate its artificial acquisition by the priesthood grammatical lists and vocabularies were compiled, and numerous religious texts were provided with literal translations into Babylonian. These have facilitated the penetration of unilingual Sumerian texts, and Sumerian studies have advanced greatly through the efforts of Delitzsch, Thureau-Dangin, Arno Poebel, Anton Deimel and Adam Falkenstein.

**Hittite and Other Languages.**—An important new dimension was added to cuneiform studies in the early years of the 20th century, through the discovery in 1906 of the royal archives of the Hittites at the ancient capital site of Hattusa near the Turkish village of Bogazköy, east of Ankara. Some years earlier the existence of an Indo-European idiom in some cuneiform letters found in the Egyptian diplomatic archives of the 18th dynasty at Tell el-Amarna had been suspected by Johan Knudtzon. This unlikely surmise was confirmed by Friedrich Hrozný during World War I, when his initial interpretation of the Bogazköy materials proved that the predominant language in the thousands of tablets was that of the Indo-European Hittites, whose rule in central Asia Minor filled most of the 2nd millennium. (See HITTITES.) The tablets offered no serious cryptological problems, being edited in a type of borrowed Akkadian cuneiform. The interpretation of the unknown language was aided by the partial ideographic nature of the script, which revealed elements of meaning independent of linguistic factors. Even more important was a series of bilingual parallel texts, in which the Akkadian versions served as a clue to the analysis of linguistic structure. This is the ideal state of affairs for recovering a lost language: it is a mixed blessing only insofar as a consistent ideography, while providing immediate comprehension, sometimes hides the underlying words to such an extent that some basic elements of Hittite vocabulary are still unknown. For example, the words for "son" and "horse" are not known, being always denoted by the Sumerian ideograms DUMU and ANŠU.KUR.RA (these are traditionally transliterated by capital letters). An added complication was that the Hittites created a secondary level of ideography by using Akkadian words or phonetic complements in the midst of a Hittite context, though this doubtless was not reflected in the pronunciation (these are transliterated by italic capitals). For example, the dative of the word for "god" is written with the Sumerian ideogram DINGIR followed by the Akkadian syllable *LIM* extracted from the oblique case *lišim* of *ilum* ("god") and a Hittite phonetic complement *-ni*: DINGIR-*LIM-ni*, pronounced *šiumi*, as is known from parallel phonetic "graphies" of the form in other occurrences.

In the Hittite religion the autochthonous Khattish, or Hattic, language held a position of cult idiom reminiscent of that of Sumerian in Babylonia; it is attested especially in rituals. In much of southern Asia Minor the predominant language was Luish, or Luwian, and in parts of the north Palā, or Palaic, both closely related to Hittite. The remains of all these at Bogazköy are written in a variety of cuneiform with few ideograms, which also characterizes the Hurrian texts in the Hittite archives and at Tell el-Amarna (the so-called Tushratta letter). The interpretation of these languages has proceeded slowly, due mostly to the paucity of texts and bilinguals. To the great mainstream of Hittitology, Hrozný, Ferdinand Sommer, Johannes Friedrich, Albrecht Goetze and Hans Gustav Güterbock have made the most memorable contributions.

In the absence of close affinity to known languages, which vouches adequate safeguards against the notoriously misleading comparative method of interpretation, inner analysis of the unknown language is the only trustworthy procedure. Hurrian and Haldian are definitely related languages, but neither may yet be safely used to explain the other. Haldian has been solved to some extent with the help of its rather free use of ideograms, and the As-

syrian versions of two bilingual inscriptions.

Excavations at Ras Shamra in 1929 unearthed the remains of Ugarit. Inscriptions in an unknown simple system of cuneiform were found; the low number of 30 different signs pointed to an alphabetic type. The use of a vertical stroke as word-divider facilitated the decipherment, which was based on the correct assumption that an early West-Semitic Canaanite dialect was involved. Thus the script was solved with astonishing speed by Hans Bauer, Edouard Dhorme and Charles Virolleaud, yielding a Semitic dialect named Ugaritic, closely related to Old Phoenician. Hurrian inscriptions in the same script were also found, as were texts in conventional Middle Babylonian cuneiform.

**Conclusions.**—The main type of cuneiform with its inventory of ideograms (including "determinatives" or "classifiers") and phonetic signs is a word-syllabic system like the Egyptian, "Hieroglyphic Hittite," Minoan-Mycenaean, Proto-Elamite, Proto-Indic and Chinese. The Sumerian system seems to be the oldest. To what extent it stimulated the origin or influenced the development of the others is a difficult problem connected with the monogenesis or polygenesis (common or multiple origin) of writing. The Phoenician consonantal script provided the new typological pattern on which the Ugaritic and Old Persian systems were constructed, keeping only the outer likeness of the wedge form.

**CUNENE:** see KUNENE.

**CUNEO**, the capital city of the province of the same name, in the Piedmont region, Italy, is 84 km. (52 mi.) S. of Turin by road and is the seat of a bishop. Pop. (1957 est.) 43,306 (commune). It stands at an altitude of 1,752 ft. on a plateau at the base of which flow the Stura di Demonte and Gesso rivers, forming at their junction the characteristic wedge (*cuneo*) from which the city takes its name. The old city has narrow streets flanked by porticoes; the modern part, which extends toward the railway station, is linked with the old by a great viaduct. Among the remarkable buildings are the cathedral (10th century; restored in the 18th); the church of S. Francesco (1227) in Lombard-Gothic style; that of S. Ambrogio (1231; reconstructed in the 18th century); the sanctuary of Sta. Maria degli Angeli (15th century); the town hall (18th century); and the Palazzo Audiffredi (18th century) which contains the civic museum. The railway station is on the Turin-Ventimiglia line. Important industries are iron and marble working, spinning and the making of cheeses, spirits and beer.

Founded in 1120 by fugitives from baronial feuds and Lombard refugees after the destruction of Milan by Frederick I Barbarossa, it became in 1382 part of the duchy of Amadeus VI of Savoy. By the armistice of Cherasco (1796) it was ceded to France. Captured in 1799 by the Austro-Russian armies, it again passed to France after the battle of Marengo (1800).

(M. T. A. N.)

**CUNIBERT, SAINT** (c. 590–c. 663), bishop of Cologne, was born of good family in the Moselle area and was educated at Trèves, where he became archdeacon. He was made bishop of Cologne in 623. At the court of the Merovingians, especially under Sigebert III (d. 656), Cunibert exercised great political influence. He encouraged missions to the Frisians.

His feast day is Nov. 12.

**CUNITZ, MARIA** (1610–1664), Silesian astronomer called the "Silesian Pallas" from her universal accomplishments, was born at Schweinitz in 1610. In 1630 she married Elias von Löwen of Pitschen in Silesia, and gained a European reputation by her *Urania propitia* (1650). This was a simplification of Kepler's tables of planetary motion called the Rudolphine tables after Kepler's patron, the emperor Rudolph II. Maria Cunitz died at Pitschen on Aug. 24, 1664.

**CUNLIFFE, WALTER CUNLIFFE**, 1ST BARON (1855–1920), English banker who in 1890 established in London the merchant banking business of Cunliffe brothers, was born in London on Dec. 4, 1855, and was educated at Cambridge. He became director of the Bank of England in 1895, deputy governor in 1911 and governor in 1913, a position he held until his retirement in 1918. He had an active part in the financing of World War I and

accompanied Arthur Balfour on his financial mission to the United States in 1917. He was created Baron Cunliffe of Headly in 1914. He died at Epsom Jan. 6, 1920.

(J. R. Lr.)

**CUNNINGHAM, SIR ALAN GORDON** (1887– ), British general who took an important part in the liberation of Ethiopia (1941), was born in Dublin, Ire., on May 1, 1887, of Scottish parentage (his brother became Adm. Viscount Cunningham of Hyndhope). Alan Cunningham was educated at Cheltenham college and the Royal Military academy, Woolwich. He joined the royal artillery and served with distinction in France in World War I. In Nov. 1940 he took command, under Gen. Sir Archibald (soon Earl) Wavell, of the British forces in Kenya, consisting mainly of south, east and west African troops with South African air support, and he invaded Italian Somaliland in Feb. 1941. In the face of great geographical and administrative difficulties, Cunningham's force achieved remarkable mobility and complete success. After occupying the Red sea ports of Chisimaio (Kismayu) and Mogadiscio (Mogadishu), he pursued the enemy into the mountainous interior and entered the Ethiopian capital, Addis Ababa, on April 6, 1941, thus enabling the exiled emperor Haile Selassie to return. Six weeks afterward, in co-operation with Gen. Sir William Platt's army advancing from the north, he secured the surrender of the main Italian forces at Amba Alagi. Cunningham left for Egypt in Aug. 1941 to command the 8th army during the first phase of Gen. Sir Claude Auchinleck's November offensive in the Libyan desert, but he returned to England shortly afterward. After the war he served (1945–48) as high commissioner in Palestine during the last troubled years of the British mandate. He was knighted in 1948.

(J. R. M. B.)

**CUNNINGHAM, ALLAN** (1784–1842), Scottish poet and man of letters, best known for the sea song "A wet sheet and a flowing sea," was born at Keir, Dumfriesshire, on Dec. 7, 1784. His father was a neighbour of Robert Burns, and Allan and his brother James became friends of James Hogg (q.v.), "the Ettrick shepherd." Allan was apprenticed to a stonemason, but contributed songs to E. Roche's *Literary Recreations* (1807). He submitted poems to R. H. Cromeke for inclusion in *Remains of Nithsdale and Galloway Song* (1810), disguising them as old ballads, and Cromeke accepted them although he may have suspected their real authorship. Through him Cunningham went to London in 1810 and while acting as secretary to Francis Chantrey, the sculptor (1814–41), wrote for *Blackwood's Magazine* and the *London Magazine*, and also published *Songs, chiefly in the Rural Language of Scotland* (1813), *Traditional Tales of the English and Scotch Peasantry* (1822) and *Songs of Scotland, Ancient and Modern* (1825), as well as dramatic and romantic poems. These have little merit, but his lyrical poems, though lacking the unself-consciousness of the true ballad, or the perfect artistry of Burns, are often memorable for their lilting rhythm and their verbal felicity. His detailed knowledge of contemporary artists made his *Lives of the most Eminent British Painters, Sculptors and Architects*, 6 vol. (1829–33), interesting, and his edition of Burns (1834) included a life containing much valuable new material. He died in London on Oct. 30, 1842.

Of his five sons, four attained distinction, the most notable being JOSEPH DAVEY CUNNINGHAM (1812–1851), whose *History of the Sikhs* (1849) was the first authoritative work on the subject. Based on first-hand knowledge acquired while serving with distinction in the Bengal engineers before and during the Sikh wars, it brought him fame as a historian but ruined his career. His allegations that certain Sikh leaders had been bought by the British, made as a result of his observations when acting as an army political agent, led to his dismissal (1850) from the post of political agent at Bhopal, to which he had been appointed in 1846. He died soon afterward, at Umballa, on Feb. 28, 1851.

**CUNNINGHAM, WILLIAM** (1805–1861), Scottish theologian and leader of the Free Church immediately after the Disruption, was born at Hamilton, Lanarkshire, on Oct. 2, 1805, and educated at the University of Edinburgh. In 1834 he received the charge of Trinity college parish, Edinburgh. At the Disruption (1843), Cunningham was sent to the United States to win support for the Free Church of Scotland. He was appointed pro-

fessor in the New college, Edinburgh, of which he became principal in 1847 in succession to Thomas Chalmers. In 1859 he was elected moderator of the general assembly. He died in Edinburgh on Dec. 14, 1861. He was one of the founders of the Evangelical alliance. The Cunningham theological lectureship at the New college was endowed in 1862.

See R. Rainy and J. Mackenzie, *Life of Cunningham* (1871).

**CUNNINGHAM, WILLIAM** (1849–1919), British economist and churchman whose most important contributions were in economic history, was born at Edinburgh, Scot., on Dec. 29, 1849. He was educated at Edinburgh, Tübingen and Cambridge and was ordained in 1873; his career as economist and economic historian overlapped his career in the Church of England. Professor of economics in University college, London, from 1891 to 1897, he was appointed vicar of Great St. Mary's, Cambridge, in 1887 and archdeacon of Ely in 1906. He became a fellow of the British academy in 1887. His principal work, *The Growth of English Industry and Commerce* (1882; later expanded to 3 vol.; 5th ed., 1910–12), is a standard reference work. A bibliography of his works will be found in his *Progress of Capitalism in England* (1916). He died at Cambridge on June 10, 1919. (Fk. L. K.)

**CUNNINGHAME GRAHAM, ROBERT BONTINE** (1852–1936), Scottish writer and nationalist, described by Joseph Conrad as a grand seigneur born out of his time, was born in London on May 24, 1852. As well as claiming descent from Robert II, he had a Spanish grandmother from whom he inherited the look of a 17th-century Spanish grandee which made him such a romantic figure. Much of his youth was spent cattle farming in the Argentine, and he traveled throughout South America, where he was so greatly respected that the new city of Don Roberto was named after him. On his father's death in 1884 he returned to the family estate and from 1886 to 1892 was Liberal M.P. for North Lanarkshire. He took an active part in the early development of the Labour party and supported the Scottish nationalist movement, being elected its first president in 1928. He died in Buenos Aires, Arg., on March 20, 1936. His essays, biographies, short stories and books of travel reveal his original and ironical mind and the directness and humanity which made him a champion of the oppressed. They include *Mogreb-el-Acksa* (1898), *Success* (1902), *Scottish Stories* (1914), *A Brazilian Mystic* (1920) and *Portrait of a Dictator* (1933).

**BIBLIOGRAPHY.**—L. Chaundy, *A Bibliography of the First Editions of the Works of R. B. Cunninghame Graham* (1936); A. F. Tschiffely, *Don Roberto* (1937); H. MacDiarmid, *Cunninghame Graham* (1952).

**CUNNINGHAM OF HYNDHOPE, ANDREW BROWNE CUNNINGHAM**, 1st Viscount (1883–1963), British naval officer who became first sea lord and chief of naval staff during World War II. He left school at an early age to train on H.M.S. "Britannia" and in 1898 entered the Royal Navy. He served with distinction in World War I and at the outbreak of World War II in 1939 was commander in chief of the Mediterranean fleet. In this capacity he directed the action in Nov. 1940 that seriously crippled the Italian fleet at Taranto. His forces later suffered serious losses in evacuating British troops from Crete. In 1942 he became head of the British admiralty delegation to Washington, D.C. The following year he returned to London to succeed Admiral of the Fleet Sir Dudley Pound as first sea lord and chief of naval staff, at which post he remained until 1946. In the latter year he was created 1st Viscount Cunningham of Hyndhope. He published a book of memoirs, *A Sailor's Odyssey* (1951). He died in London on June 12, 1963.

**CUNOBELINUS** (1st century A.D.), sometimes called Cymbeline, was the son of the Catuvellaunian chief Tasciovanus, and conquered the Trinovantes of Britain early in the 1st century. He established a mint at Camulodunum (Colchester), was styled by Gaius Suetonius Tranquillus *Britannorum rex*, and employed the title *rex* on his coins. Three sons are known, Adminius, who was exiled and fled as a suppliant to the emperor Caligula (Gaius Caesar) in A.D. 40; Togodumnus, who was killed resisting the Claudian invasion, and Caractacus, who had carved out a kingdom among the Atrebatas and continued resistance among the Silures and Ordovices until defeated and captured in A.D. 50.

See D. Allen in *Archaeologia*, xciii, 20–29 (1949). (I. A. Rn.)

**CUPAR**, a royal and small burgh and the county town of Fifeshire, Scot., 18 mi. N.N.E. of Kirkcaldy by road. Pop. (1961) 5,495. It is situated on the left bank of the Eden, in the east of the Howe (Hollow) of Fife, and is sometimes called Cupar-Fife to distinguish it from Coupar Angus in Perthshire. The mercat (market) cross stands at the meeting of the three main streets, where it was set up in 1897 after its removal from nearby Tarvit or Wemysshall hill, 2 mi. S., whence it was taken from the town in 1817. The hill is allegedly the spot where a treaty was signed in 1559 between Mary of Guise and the lords of the congregation. The town received a charter from DAVID II (1356), Robert II (1381) and other kings, and being situated between Falkland and St. Andrews was constantly visited by Scottish royalty. The site of the 12th-century castle of the Macduffs, thanes of Fife, is occupied by a school. Along the northern slopes of Castle hill stretched the Playfield where morality plays were performed. There took place an early performance of Sir David Lyndsay's *Ane Satyre of the Thrie Estais* and his *Tragedie of the Cardinall* (1547), referring to the murder of Cardinal David Beaton. Of the Benedictine monastery that stood on the southern side of the castle no trace remains. The tower of the parish kirk survives from the original church built in 1415.

The chief industries are linen, tanning and engineering; there are beet sugar and flax factories and the town has a reputation for printing. It has long been the market town of the Howe of Fife and on Tuesdays a cattle and grain market takes place.

To the northeast (3 mi.) is the village of Dairsie, where one of the few parliaments that ever met in Fife assembled in 1335. In the upper Old Red Sandstone of Dura Den, a ravine on Ceres burn, 3 mi. E. of Cupar, have been found great quantities of fossils of ganoid fishes.

**CUPBOARD:** see CABINET FURNITURE.

**CUPID**, Roman counterpart of the Greek Eros (q.v.), son of Venus, equivalent to Amor in Latin poetry. From earliest Roman literature Cupid is seen as a playful boy shooting arrows of passion. In the 1st century B.C. and later, he constitutes a standard theme of Roman wall paintings at Pompeii, and Greek statues of him were brought to Rome and copied. According to Pliny, Varro owned a famous Cupid by Arcesilaus, and one of Praxiteles' masterpieces graced a Roman portico. Cupid plays a prominent part in Latin love elegy from the time of Catullus, particularly in the more sophisticated works of Propertius and Ovid, where Cupid ironically assumes the formidable qualities of an invincible warrior. In the *Aeneid*, Cupid helps to destroy Dido's honour (*Aeneid* 1, 657 ff.); in Ovid's *Metamorphoses* he inspires passion in Apollo and Pluto. The Romans carved Cupids, often sleeping or drunken, on sarcophagi; in these cases, he represented the pleasant sleep of death or a beneficent spirit.

For Cupid and Psyche, see PSYCHE. (Wm. S. A.)

**CUPOLA FURNACE**, a vertical type, cylindrical, or shaft furnace designed to melt ferrous metal in the production of cast-iron castings. It also has been employed to melt scrap iron and pig iron for charging in specialized furnaces, as the Bessemer and side-blow converter used in steel making. The cupola, which is similar in principle to the blast furnace (q.v.), consists of a refractory-lined steel stack 20 to 35 ft. high, resting on a cast-iron base plate which is supported by four steel legs. The bottom of the cupola consists of two hinged doors which are supported in closed position by a centre prop. Molding sand is rammed over the closed bottom doors to support the coke bed, molten metal and succeeding charges. Forced air for combustion enters the cupola through openings known as tuyères which are situated around the periphery of the lower portion of the cupola; sometimes the air is preheated. Iron, coke and flux (limestone) are charged onto a coke bed of sufficient height to hold the iron charges above the tuyère openings where the maximum temperature is maintained. Melting is continuous and molten metal may be allowed to flow continuously through an open tap hole at the base of the cupola or it may be tapped intermittently. Intermittent tapping is done by piercing a clay bott (plug) in the tap hole with a steel pointed rod, creating a passageway through the clay

DIAGRAM OF THE CUPOLA FURNACE

portion known as the "breast" of the cupola. The tap hole is stopped up again by plugging it with a fresh clay bott. Wastes in the form of slag flow out of the cupola when the slag hole is tapped. Continuous cupola operation may go on without interruption from 1 to 16 hours and even longer. At the end of melting operations, the prop which supports the bottom doors is pulled out, allowing the doors to swing open and discharge all the remaining contents of the cupola.

The first cupola on record was built by R. A. Ferchault de Réaumur in France about 1720, and the furnace was introduced in the United States in 1820.

Cupola melting is still recognized as the most economical melting process, and most of the gray iron (see CAST IRON) produced is melted by this method. (C. T. M.)

**CUPPING**, a method of medical treatment, long obsolete, whereby blood was drawn to some cutaneous region by the partial vacuum within a heated cupping glass (dry cupping). In wet cupping the skin was incised. In both instances, as in the action of leeches, there was local abstraction of a small quantity of blood which was held to relieve subjacent inflammation.

**CUPRESSACEAE**, the cypresses and junipers, is one of the largest and most widespread families of coniferous trees and shrubs. Many are important timber plants or serve as sources of oils, resins or tannins. They are also extensively cultivated for ornament.

There is no general agreement as to the number of genera but the following are customarily recognized: *Cupressus* (true cypress), *Chamaecyparis* (false cypress), *Cupressocyparis* (an intergeneric hybrid), *Arceuthos*, *Juniperus* (juniper), *Actinostrobus*, *Callitris*, *Tetraclinis*, *Callitropsis*, *Widdringtonia*, *Fitzroya*, *Diselma*, *Thujaopsis*, *Libocedrus*, *Pilgerodendron*, *Fokienia*, *Thuja* (arbovitae), *Biota* and *Microbiota*.

The leaves of the Cupressaceae are always opposite or whorled and often in flattened branchlets. The staminate, or pollen-bearing, cones are at the ends of short twigs, and the scales, opposite or in threes, bear three to six sporangia. The ovulate, or seed-bearing, cones are terminal with opposite or whorled cone scales which consist of fused bract and scale, these becoming thick and woody, or sometimes fleshy, at maturity. The erect ovules are attached near the base or appear axillary. There are four main types of embryogeny within the family, including both cleavage and simple polyembryony. The number of cotyledons ranges from two to six.

See CONIFERS; GYMNOSPERMS.

(R. W. H.; X.)

**CUPRITE**, a mineral consisting of cuprous oxide,  $\text{Cu}_2\text{O}$ , is an important ore of copper (*q.v.*), of which it contains 88.8%. The name cuprite (from the Latin *cuprum*, "copper") was given by W. Haidinger in 1845; earlier names are red copper ore and ruby copper, which at once distinguish this mineral from cupric oxide, known as black copper ore or melaconite.

Cuprite occurs in the reduction zone of copper-bearing lodes, and is of secondary origin. It is found in Europe, Australia,

Africa and South America. In the United States it occurs in the copper districts of the southwest, as at Bisbee, Ariz. Well-developed crystals are of common occurrence, and beautifully crystallized specimens were formerly found in Cornwall; they also occur in the copper mines of the Urals, in Arizona and elsewhere.

Cuprite crystallizes in the cubic system and crystals usually have the form of the regular octahedron, sometimes in combination with the cube and the rhombic dodecahedron. The colour is cochineal-red, and the lustre brilliant and adamantine to submetallic in character; crystals are often translucent, and show a crimson red colour which on prolonged exposure to light becomes dull and opaque. The streak is brownish-red. Hardness 3.5; specific gravity 6.0; refractive index 2.85.

Compact to granular masses also occur, and there are two curious varieties—chalcotrichite and tile-ore—which require special mention. Chalcotrichite (from the Greek words for copper and hair) or "plush copper ore" is a capillary form with a rich carmine colour and silky lustre: the delicate hairs are loosely matted together, and each one is an individual crystal enormously elongated in the direction of the edge of the cube. Tile-ore is a soft earthy variety of a brick-red to brownish-red colour; it contains admixed limonite, and has been formed by the alteration of chalcopyrite (copper and iron sulfide).

(L. J. S.)

**CURAÇAO**, the largest island of the Netherlands Antilles (*q.v.*), lies in the Caribbean sea 60 mi. off the Venezuelan coast. Its length is 40 mi., average width 10 mi., and area 182 sq. mi. It consists of igneous rocks and is mainly flat, except in the northwest where hills rise to 1,230 ft. Deep bays indent the south coast, the largest of which, the Schottegat, provides a magnificent harbour for the capital, Willemstad (*q.v.*). The landscape is barren due to low rainfall (about 20 in. a year) and sparse vegetation. Large areas support only cactus thickets and there is much bare, eroded soil, the result of centuries of over-grazing.

Curaçao was discovered by Alonso de Ojeda in 1499 and settled in 1527 by the Spanish, who used it mainly for livestock raising; in 1565 John Hawkins described it as "one great cattle ranch." In 1634 Johannes van Welbeck of the Dutch West India company occupied and fortified the island, which became the base for a rich entrepôt trade flourishing through the 18th century. During the Napoleonic wars it was held by Great Britain but was returned to the Netherlands by the treaty of Paris, 1815. The 19th century was a time of economic decline, alleviated only by such ventures as the cultivation of aloes for pharmaceutical products and oranges for Curaçao liqueur.

The prosperity of Curaçao dates from 1914 when the Lake Maracaibo oilfield in Venezuela was first exploited by Royal Dutch Shell. A large refinery, built beside the Schottegat, began operating on Curaçao in 1918. It refines crude petroleum from Venezuela and Colombia. The industry supports most of the island's population and oil products are the only important export. Minor industries are calcium phosphate mining in the east, and tourism. Foreign trade is mainly with the United States and Venezuela, and Curaçao has been a free trade zone since 1956.

In 1960 the total population was 125,181, about 50,000 of whom lived in Willemstad. Curaçao has an extensive road system and is linked to the outside world by Dutch, U.S. and Venezuelan airlines as well as by numerous steamship services. (D. R. H.)

**CURAÇAO**, an alcoholic beverage originating in the Dutch island of Curaçao and deriving its principal flavour from the peel of the native orange of the same name. Its production later found favour in continental Europe, where its original formulation as a liqueur of the Curaçao orange was modified. It was then produced as an alcoholic distillate and infusion of the bitter as well as the sweet orange peel, compounded with sirups, brandies, rum, ethereal oils or spice isolates.

Varieties include Curaçao de Marseille, Pomeranzen, Ratafia

BY COURTESY OF THE NATURAL HISTORY MUSEUM

CUPRITE, CRYSTALLIZED SPECIMEN

Curaçao, Grand Marnier, Triple Sec, all related orange flavoured potions of variant quality and ranging from 30% to 40% alcohol with their corresponding sugar content 30% to 23%. The liqueur is fined and is recognized among connoisseurs in either white or brown coloured varieties, likewise as a sweet or dry palative of a delicate nature.

Its prime essence is employed in a number of bitters and occasionally as a carminative. (D. An.)

**CURARE** (D-TUBOCURARINE or INTOCOSTRIN; obsoletely or primitively called curari, wourara, wourari, wourali, urari, curara, urirarery, etc.), a nonspecific term used by certain South American Indians to designate a group of varying but related arrow poisons; in pharmacognosy and medicine, specifically a form of curare like that discovered by R. C. Gill in 1938, used in human beings to induce muscle relaxation.

Curare produces flaccidity in striped (skeletal, or voluntary) muscles, and is used most widely as an auxiliary in general inhalation anesthesia, especially in abdominal surgery. In that field, frequently in association with cyclopropane gas, it is particularly useful because it produces profound surgical relaxation (comparable only with that seen in spinal anesthesia) with a minimal concentration of anesthetic agent. From this there is prompt post-anesthetic recovery and a radical reduction of the possibilities of postoperative pneumonias and other complications. The drug is also employed as a relaxant in oral intubation, general endoscopy (oral, rectal, etc.), various tetanic seizures and lumbar and sacroiliac manipulations. Because of its quickly reversible action, it is useful in the diagnosis of myasthenia gravis. Curare also is used for relief of spastic paralysis (by reducing to normal the tone of hyperinnervated muscles), in the reduction of fractures and dislocations (by eliminating muscle pull during setting or reduction) and in other fields where a state of profound muscular relaxation or even immobility is desirable. Another use is as an adjunct in the shock therapy of schizophrenia and various other mental disorders, in which it is claimed to reduce the incidence of vertebral fractures.

Since curare can cause respiratory depression or arrest if administered in overdose or too rapidly, a carefully controlled technique of administration is necessary. It may be given either intramuscularly or intravenously.

Crude curare is a resinous-appearing, dark-brown to black mass of a sticky to hard consistency and has an aromatic, tarry odour. It is frequently prepared by the Indians as a decoction (though often also as a cold concoction). The types of curare most often studied have each contained several ingredients, variously grouped, from several botanical families. Of primary importance are the Loganiaceae (*Strychnos* species) and Menispermaceae (*Chondodendron*, *Cissampelos*, *Sciadotenia*, *Telotoxicum*, *Elissarrhena*, *Anomospermum* species, etc.); of secondary, and even rare, use are the Piperaceae (*Piper* species), Annonaceae (*Annona*), Leguminosae (*Lonchocarpus*), Rutaceae (*Erythroxylon*), Moraceae (*Ficus*), Rubiaceae (*Psychotria*), Solanaceae (*Capsicum*) and Aristolochiaceae (*Aristolochia* species).

Different curares contain one or more of the following complex basic alkaloids: curin(e), curarine, tubo-curarine, paracurarine, protocurarine, the phenolic alkaloids protocuradine and neo-protocuradine, and others.

See also ANESTHESIA AND ANESTHETICS.

**BIBLIOGRAPHY.**—A. R. McIntyre, *Curare: Its History, Nature and Clinical Use* (1947), contains extensive bibliographies; see also R. C. Gill, *White Water and Black Magic* (1940); K. R. Unna et al., *New York Academy of Sciences, Curare and Anti-Curare Agents* (1950). (R. C. GL.; X.)

**CURASSOW**, a group of fowl-like (gallinaceous) birds comprising several genera (*Nothocrax*, *Mitu*, *Pauxi*, *Crax*) of the family Cracidae. They are among the finest game birds of tropical America and resemble turkeys superficially, having short wings, long broad tail, strong legs and large feet. The hind toe is on a level with the other toes, unlike the condition in the majority of gallinaceous birds. The plumage may be glossy black, black and white or reddish brown. Many species are crested and some casqued. In most species the sexes are similar in colour.

With the exception of one species found north of Panamá, the

curassows are confined to South America, principally east of the Andes and south to northern Argentina. They have heavy flight, and usually live in small flocks. Although essentially arboreal, they often forage on the ground, feeding chiefly on fruits and leaves. The nest is a simple structure of sticks or leaves placed in trees. The white eggs, two or three in number, apparently are incubated by the female. The downy young have striped heads, and leave the nest shortly after hatching. Although often tamed, curassows have never been thoroughly domesticated.

The Mexican great curassow (*Crax rubra*), about three feet long, lives in lowland forests from southern Tamaulipas to western Ecuador. Males are glossy black except for the white abdomen and tail coverts; females are reddish brown. Both sexes have conspicuous erectile crests with recurved tips. (E. R. BE.)

**CURB MARKET** (STREET MARKET), a name given to any stock market which either now transacts or originally transacted its business in the open, presumably in the streets or upon the curbs. At the outset, the curb markets of the various cities were entirely unorganized and operated only through the custom of a number of brokers meeting at certain places. Now they are well-organized exchanges, most of them well housed.

The London street market operated in 'Change alley during most of the 18th century. It is known that a street market existed in Paris in 1720, for records show that a part of the Rue Quincampoix was roped off at the time of the Mississippi Bubble to protect the street traders from the general public. In Boston the curb market operated in Exchange place for years before going into its present building.

The New York Curb exchange had its origin before the Civil War when its meeting place was located in Wall street near Hanover street. During the war it functioned in William street between Exchange place and Beaver street. In those days trading began at 8 A.M. and continued until 6 P.M. or later and, at night, was carried on in the corridors of uptown hotels. From 1880 to 1900 it was carried on at all hours in front of the Mills building in Broad street but after 1900 was reduced to a regular session from 10 A.M. to 3 P.M. Later the open-air traders located opposite 44 Broad street just south of Exchange place. A more closely knit organization was formed in 1908 and known as the New York Curb agency.

The modern exchange, under the name of the New York Curb market, or Market association, was organized as a voluntary association in 1911. The official title was changed to New York Curb exchange in 1929. On Jan. 5, 1953, the name was again changed to American Stock exchange. See also STOCK EXCHANGE.

**CURÉ D'ARS**: see VIANNEY, SAINT JEAN BAPTISTE MARIE.

**CUREL, FRANÇOIS, VICOMTE DE** (1854–1928), French dramatist whose plays introduced a new range of ideas to the French stage, was born at Metz on June 10, 1854. Trained as a civil engineer, Curel obtained an opening as a dramatist when the Théâtre Libre accepted three plays (1891). His early plays are purely psychological studies. Subsequently Curel dramatized such themes as relations between capital and labour (*Le Repas du lion*, 1897); the misdirected cult of science (*La Nouvelle idole*, 1899); the persistence of the animal in civilized man (*La Fille sauvage*, 1902; and *L'Ame en folie*, 1919). His plays are known as "dramas of ideas," but he maintained that his interest in ideas lay only in their power to inspire passion and promote action (see *La Comédie du génie*, 1921, and prefaces to other plays). His one popular success was *Terre inhumaine*, a war play (1922), translated as *No Man's Land*. Curel died in Paris on April 25, 1928.

See E. Pronier, *La Vie et l'oeuvre de F. de Curel* (1934). (D. KS.)

OLIN S. PETTINGILL, JR., FROM NATIONAL AUDUBON SOCIETY  
MEXICAN GREAT CURASSOW (*CRAX RUBRA*)

**CURETES**, a word with two meanings:

1. A people who fight the Calydonians in the quarrel arising out of the boar hunt. (See MELEAGER.) Later writers placed them in Actolia, Acarnania or Chalcis.

2. Certain diamones connected with the cult of Rhea and regularly conceived as the attendant band of the infant Zeus. In historic times they had a certain amount of cult in various parts of the Greek world, which comprised Pyrrhic dances (i.e., war dances in armour). In cult, art and literature they are frequently confused with the Corybantes (see CORYBANT), but their proper home is Crete and their proper function attendance on Zeus and Rhea. Names of several of them point to these facts, as Kres (Cretan) and Labrandos (he of the double ax, *labrys*, a very old Cretan and Asiatic sacred symbol). The legend states that when Zeus was born in, or conveyed in infancy to, Crete, they danced and clashed their weapons to drown his cries. A highly interesting hymn in their honour was discovered at Palaikastro in Crete; the worshipers call on Zeus Kouros and his attendants to bring all manner of fertility.

It is a not improbable supposition that the original Curetes were the human worshipers of Zeus Kouros (i.e., that the *kouroi*, "adolescent boys," worshiped a god supposed to be of their own age, a variant of the "infant" Zeus of Crete); that the object of their worship was the increase of fertility, vegetable and animal; and that, although the hymn is of Hellenistic date, the rite itself may go back to Minoan times. It is also possible that the Curetes who fight the Calydonians are in their origin nothing but the young warriors of the neighbouring states.

**BIBLIOGRAPHY.**—The text of the hymn is best given in Powell, *Collectanea Alexandrina* (1925); other texts are cited in Immisch. See also J. E. Harrison, *Themis*, 2nd ed. (1927); M. P. Nilsson, *Minoan-Mycenaean Religion* (1927).

**CURFEW** (from O.F. *cuevrefu*, "cover fire"), a signal, as by tolling a bell, to warn the inhabitants of a town to extinguish their lights and fires or cover them up and retire to rest. This was a common practice throughout Europe during the middle ages. In medieval Venice the Barbers' quarter was exempt, doubtless because they were also surgeons and their services might be needed during the night. The curfew originated in the fear of fire when most cities were built of timber. Its use is obvious, as the household fire was usually made in a hole in the middle of the floor, under an opening in the roof through which the smoke escaped. The custom is said to have been introduced into England by William the Conqueror; but as there is good reason to believe that the curfew bell was rung each night at Carfax, Oxford, in the reign of Alfred the Great, it would seem that all William did was to enforce more strictly an existing regulation. The absolute prohibition of lights after the ringing of the curfew bell was abolished by Henry I in 1100. The practice of tolling a bell at a fixed hour in the evening, still extant in many places, is a survival of the ancient curfew. In 1848 the curfew was still rung at Hastings, Sussex, from Michaelmas to Lady day, and this was the custom too at Wrexham, north Wales.

On April 2, 1918, the British board of trade, with a view to economy in the consumption of coal, introduced the "curfew order," rescinded on Dec. 23, 1918, which restricted restaurant, theatre and shop-front lighting. Similar orders have since been issued and enforced during periods of unrest, as by the British military authorities in Ireland in the early 1920s and in Cyprus in the 1950s, and by the German military authorities in occupied Europe during World War II.

**CURIA**, an ancient political division of the Roman people. According to Roman tradition, Romulus divided the people into three tribes and 30 *curiae*, each of which in turn was composed of families (*gentes*). Citizenship depended on membership in these kinships, which probably included both the patricians and the much less important plebeians. Yet regional associations of the *curiae* are indicated in some names, though others were personal. They were the political units which composed the primitive assembly of the people, the *comitia curiata*, and were the basis of the early military organization. Though they lost their political and military importance to the later organizations by tribes and

centuries (see *COMITIA*), certain formal and religious functions survived. For these purposes each *curia* had its own organization headed by a *curio* with a priest or *flamen* to assist him, while the head of the college of *curiones* was the *curio maximus*, always a patrician until a plebeian was elected in 209 B.C. The *curiae* had individual sacred rites, such as those to Juno and those performed by each *curia* at the "feast of ovens" (Fornacalia) on Feb. 17 and the "sacrifice of pregnant cows" (Fordicidia) on April 15, festivals which also had general public rites under the charge of the *curio maximus*.

Meeting places of the *curiae* were also called *curiae*, which gave rise to such terms as *Curiae Veteres* and *Curiae Novae*. The term was then applied to other meeting places, such as the *Curia Calabra*, where religious announcements concerning the calendar were made, and the *Curia Saliorum* (see *SALII*), and particularly to the senate house, the *Curia Hostilia*, its successor the *Curia Julia*, and finally by metonymy to the senate itself. *Curia* was also a regular title for the wards or voting divisions of colonies and *municipia*, both in Italy and in the western provinces. Under the later empire it appears also as a term for the local *senates* or boards of *decuriones* (see *DECURIO*), while their members were termed *curiales*.

In medieval Latin the word *curia* was used in the general sense of "court." It was used of "courts" in the sense of solemn assemblies summoned by the king (*curiae solennes*); of courts of law, whether developed out of the imperial or royal *curia* (see *HOUSEHOLD*, *ROYAL*) or not. Sometimes *curia* means jurisdiction, or the territory over which jurisdiction is exercised, whence its use for the courtyard of a house, or for the house itself; e.g., Hampton Court. The word "curia" is now used only of the papal court of Rome.

**CURIA REGIS:** see *HOUSEHOLD*, *ROYAL*.

**CURIA ROMANA**, that is, the Roman curia or court, is the name properly given to the group of departments and persons used by the pope in the exercise of his supreme and universal power over the Roman Catholic Church. It comprises the Roman congregations, the tribunals of the curia and the offices of the curia. For the papal court in the sense of the pope's personal entourage, see *VATICAN*.

In the first three centuries of Christianity the pope was chiefly assisted by the Roman clergy and by neighbouring bishops; for instance, the seven Roman deacons were entrusted with the care of the poor. From the time of the emperor Constantine I onward into the middle ages important affairs were handled by the Roman synods, either provincial or (later) general; but later in the middle ages the popes began increasingly to avail themselves of the assistance of the cardinals (see *CARDINAL*). The deliberative functions of the synods were taken over by the papal consistory; and individual cardinals were set over particular spheres of business, other cardinals being associated with them.

The first pope, however, authoritatively to organize a permanent system of agencies for the dispatch of all ecclesiastical business was Sixtus V, by the constitution *Immensa* on Jan. 22, 1588 (new style; 1587, old style). He established 15 congregations, most of them designed to assist the pope in the spiritual affairs of the church, but a few for the administration of the papal states. His dispositions, modified by Clement VIII, by Gregory XV, by Urban VIII (who added the Congregation for the Propagation of the Faith), by Clement IX and by Pius VII (who added the Congregation for Extraordinary Ecclesiastical Affairs), obtained in substance until 1908.

Pius X, however, saw that the efficiency of the Sixtine organization had gradually deteriorated: the competency of the several organs was indistinct, some were overworked, others idle. He therefore proceeded to a reform of the curia with the constitution *Sapienti consilio* of June 29, 1908. By this, some congregations

were amalgamated with others; the competency of each was defined; all affairs concerning the discipline of the sacraments were entrusted to a new congregation created for that purpose; all judicial business except certain specified cases was withdrawn from the congregations and committed to the Rota or to the Signatura, two tribunals which had previously found themselves with nothing to do; and general rules were laid down for the expedition of business and regarding personnel. The ordinances of *Sapienti consilio* and of its annexed *Ordo servandus in ss. congregationibus, tribunalibus et officiis romane curiae* were received, with some small changes, into the Code of Canon Law (1917).

**Roman Congregations.**—There are 11 congregations: the Congregation for the Doctrine of the Faith (formerly the Holy Office), the Consistorial Congregation and the Congregations of the Sacraments, of the Council, of Religious, for the Propagation of the Faith, of Sacred Rites, of Ceremonial, of Extraordinary Ecclesiastical Affairs, of Seminaries and Universities, for the Oriental Church. A 12th, the Congregation of the Basilica of St. Peter, is not considered as such by the code. Meetings of the members of a congregation are always held in the Vatican, except those of the Congregations of the Doctrine of the Faith and of the Propagation of the Faith, which have their own palaces.

Each congregation is headed by a prefect. The pope himself holds the prefecture of three: the Congregation for the Doctrine of the Faith, the Consistorial Congregation and the Congregation for the Oriental Church. These are actually directed by a cardinal secretary, who is assisted by a prelate called the *adessor*. The prefects of the other congregations are cardinals, each assisted by a secretary (a prelate, often a titular archbishop). Only cardinals are members of the congregations themselves; but they are assisted by various officials, and each congregation also has its "consultors."

The competence of the congregations is administrative and disciplinary. They must send cases requiring judicial decision to the competent tribunal (except certain specified cases which the Sacred Congregations for the Doctrine of the Faith, of Rites and of Sacraments are competent, severally, to decide); and legislative power is reserved to the pope. The functions of each congregation are defined by the code (canons 247-257); collectively, they comprise care for the faithful observance of the laws of the church, the issuance of instructions to explain or confirm the law, the practical application of legal prescriptions to particular cases, the concession of faculties *secundum vel praeter ius*, the granting of dispensations, the application of disciplinary measures and the resolution of doubts, questions and controversies in disciplinary (nonjudicial) form. The authority of a congregation, within its own competence, is supreme and universal; it is also ordinary, but vicarious (it is possessed by the congregation in virtue of law, but exercised by it in the name and by the authority of the pope). Congregations do not share in the fullness of the papal power or in the pope's infallibility; their acts are reformable, unless confirmed in specific form by the pope.

**Tribunals.**—The tribunals of the Roman curia are three: the Sacred Penitentiary, which judges questions of conscience and has authority only over the conscience of the individual; the Sacred Roman Rota; and the Apostolic Signatura. The latter two have external authority.

The Rota consists of a college of prelates auditors, who, sitting in groups of three (hence the name, which means "wheel"), form judicial commissions which give judgment on matters coming under ecclesiastical law (except certain cases reserved to the Sacred Congregations for the Doctrine of the Faith, of Rites and of Sacraments). The Rota hears appeals from diocesan courts all over the world and judges certain important matters in the first instance. Many of the cases dealt with concern nullity of marriages. The judges or auditors, generally about 15 in number, are nominated by the pope; they are among the senior prelates of the Curia Romana and enjoy many privileges.

The Signatura is composed of cardinals, who consider appeals lodged against decisions of the Rota. It cannot decide on the merits of the question, but may consider whether there has been any error of procedure sufficiently important for the case to be

referred back to the Rota, where it will be considered by other judges than those who dealt with it the first time.

**Offices of the Curia.**—The chief of the five offices is the Secretariat of State. This office is directly controlled by the cardinal secretary of state, whose position in relation to the pope corresponds to that of a prime minister. With the assistance of the Congregation of Extraordinary Ecclesiastical Affairs, which constitutes the first of its three sections, this secretariat deals with all business connected with relations between the Holy See and the various governments. The cardinal secretary and his office are responsible for all matters in which some measure of agreement with a secular authority is necessary (concordats, the nomination of bishops, etc.) and also for the instructions to be given to the faithful on questions relating to national political life. Every day, before dealing with other business, the pope receives the cardinal secretary of state or one of the prelates responsible for the three sections of the secretariat. When we speak of the attitude or policy of the Vatican, we generally mean the activity of the Secretariat of State or the papal diplomacy for which it is directly responsible.

The other offices are the Apostolic Cancellaria, which deals with the dispatch of papal bulls; the Apostolic Dataria, which deals with benefices the grant of which is reserved to the Holy See; the Apostolic Camera, which has charge of the property of the Holy See, especially in the interval between the death of a pope and the election of his successor; and the Secretariat of Briefs to Princes and of Latin Letters, which deals with Latin letters from the pope.

**CURICÓ**, a province of central Chile bisected by the parallel 35° S. and extending from the Pacific to the Argentine frontier. Colchagua and Talca provinces adjoin, respectively, to the north and south. The province was created in 1865, dissolved in 1927, and reformed in 1936. It is subdivided administratively into Curicó and Mataquito departments. Area 2,033 sq.mi., pop. (1960) 105,839. About 50% of the gainfully employed are in agriculture and wheat, improved pasture, rice, the vine, legumes, maize, potatoes and orchards are cultivated. Cattle and sheep are raised in large numbers on the range land of the coastal mountains and Andean cordillera. Valley pastures are used primarily for finishing local stock and the cattle shipped in from the south. The province is noted for its stock auctions, rodeos and horsemen.

Curicó city (pop. [1960] 51,702 mun.), provincial capital and departmental seat, was founded in 1743 by José Antonio Manso de Velasco as San José de Buena Vista de Curicó and was elevated to city status in 1830. An earthquake largely destroyed the city in 1928. Licantén (pop. [1960] 6,544 mun.), seat of Mataquito department, has rail and road communication with Curicó. The latter is on the main line longitudinal railway and paved highway. Small beach and mountain resorts exist. Mining is unimportant although precious and industrial minerals have been reported.

(J. T.)

**CURIE, PIERRE** (1859-1906) and **MARIE** (MARJA SKŁODOWSKA) (1867-1934), French physicists, were the discoverers of radium and Nobel prize winners for physics in 1903 (Mme Curie for chemistry in 1911). Pierre Curie was born in Paris on May 15, 1859, and educated at the Sorbonne, where he later became professor of physics. His early researches were piezoelectricity, the magnetic properties of bodies at different temperatures and other topics. One of his most important contributions to physics was the discovery that the magnetic properties of substances change at a certain temperature. This temperature is known as the "Curie point." He became chiefly known, however, for his work on radioactivity carried out jointly with his wife, Marie Skłodowska, to whom he was married in 1895. Marie Skłodowska was born in Warsaw on Nov. 7, 1867, and received her early scientific training from her father. She became involved in the students' revolutionary organization and found it advisable to leave Warsaw. Mlle Skłodowska went first to Cracow, then under Austrian rule, and later to Paris, where she took a science degree at the university.

After the discovery of the radioactive properties of uranium by Henri Becquerel in 1896, the Curies began researches into radioactivity (*see* RADIOACTIVITY), and in 1898 they an-

nounced they had discovered two new elements in the mineral pitchblende. These were polonium (named for Mme Curie's native country) and radium. In later years they did much to elucidate the properties of radium and its transformation products. The work of the Curies laid the foundation for much of the later research in nuclear physics and chemistry.

In 1903 they were awarded the Davy medal of the Royal society and in the same year the Nobel prize for physics was divided between them and Henri Becquerel. They received the Nobel prize for the discovery of radioactivity. The same year Mme Curie submitted the results of her researches in her doctorate thesis presented to the university. She then became head of the laboratory at the department of the Sorbonne created for her husband.

Pierre Curie, who was elected to the Academy of Sciences in 1905, was run over by a dray and killed in Paris on April 19, 1906.

CULVER PICTURES  
PIERRE CURIE

His widow succeeded him as professor at the Paris university and in 1911 was awarded the Nobel chemistry prize for the discovery of radium and the study of its properties.

Her *Recherches sur les substances radioactives* was published in 1904, and her classic *Traité de radioactivité* was published in 1910. She did much to help the establishment of the radioactivity laboratory in her native city. In 1921 Pres. Warren G. Harding, on behalf of the women of the United States, presented her with a gram of radium in recognition of her services to science. In 1929 Mme Curie received from

BROWN BROTHERS  
MARIE CURIE

Pres. Herbert Hoover \$50,000 from American friends of science to purchase radium for the use of the laboratory in Warsaw. She died on July 4, 1934, at Savoy, France.

The Curies' daughter, Irène Joliot-Curie, and her husband, Frédéric Joliot (*qq.v.*), were awarded the 1935 Nobel prize for chemistry.

**BIBLIOGRAPHY.**—Eve Curie, *Madame Curie* (1937); M. Curie, *Pierre Curie* (1923).

**CURIE**, a unit of measure of the "specific activity" of a radioactive preparation. It is not to be confused with another unit also unfortunately called the specific activity; the latter is defined as the ratio of the number of atoms of a particular radioisotope to the total number of atoms of the same element.

The curie, named in honour of Marie Curie, is a unit that expresses the specific activity of radioactive material in terms of the rate at which unit weight of the material decays; *i.e.*, emits charged particles. Since it is by the experimental detection of charged particles (or their associated gamma rays) that radioactivity is most readily recognized, the curie is thus a very practical unit. Originally defined as the activity of a quantity of radon in radioactive equilibrium with one gram of radium in 1930, the International Radium Standard commission, meeting in Brussels at the Radiology congress, extended the definition of the curie to be the equilibrium quantity of any decay product of radium.

Since one gram of radium undergoes about  $3.7 \times 10^{10}$  disintegrations among its atoms every second, the present definition of the curie needs to make no specific reference to radium but is taken

as the specific activity of any material which signalizes a rate of decay of  $3.7 \times 10^{10}$  disintegrations per second per gram, this weight including that of both stable and unstable (active) isotopes of the material.

For example, if a catalogue states that some radioactive preparation, such as phosphorus-32, has a specific activity of 50 millicuries per gram, this indicates that in it there are taking place  $50 \times 3.7 \times 10^7$  disintegrations per second—*i.e.*,  $1.85 \times 10^9$  beta particles emitted per second (phosphorus-32 being a pure beta emitter). See RADIOACTIVITY; PHYSICAL UNITS. (H. B. LM.)

**CURIO, GAIUS SCRIBONIUS** (d. 53 B.C.), Roman statesman and orator, son of a distinguished orator of the same name flourished during the 1st century B.C. He opposed Saturninus in 100 B.C., was tribune in 90 B.C., and served in Sulla's army in Greece against Archelaus, general of Mithradates, and as his legate in Asia, where he was commissioned to restore the kings of Bithynia and Cappadocia to their thrones. In 76 he was consul and as governor of Macedonia (75–73) defeated the Dardanians, being the first Roman general to penetrate as far as the Danube. On his return he was granted a triumph. In 63, during the discussion as to the punishment of the Catilinarian conspirators, he supported Cicero, but he spoke in favour of P. Clodius (*q.v.*) at his trial (61). This led to a violent attack on the part of Cicero, but it does not appear to have permanently impaired their friendship. He was *pontifex maximus* in 57, published a dialogue against Caesar in 55, and died in 53.

**GAIUS SCRIBONIUS CURIO** (d. 49 B.C.), son of the above, was first a supporter of Pompey. In 59 B.C. he was implicated in a conspiracy alleged by L. Vettius to exist against Pompey. When elected tribune for 50 B.C. he went over to Caesar, by whom he was said to have been bribed. When it was demanded that Caesar lay down his imperium before entering Rome, Curio proposed that Pompey do the same, adding that, if the rivals refused to do so, they ought both to be declared public enemies. His proposal was carried by a large majority, but, a report having spread that Caesar was on the way to attack Rome, the consuls called upon Pompey to undertake the command of all the troops stationed in Italy. Curio's protest to the people to prevent the raising of an army by Pompey was disregarded, whereupon he fled to Ravenna to Caesar. He was commissioned by Caesar to take a message to the senate, but met with so hostile a reception that he hurried back by night to Caesar. It was now obvious that civil war would break out. Curio collected troops in Umbria and Etruria for Caesar, who sent him to Sicily as *propraetor* in 49. After some successes against the Pompeians, Curio crossed over to Africa, where he was defeated and killed by Juba, king of Numidia. Curio possessed great ability; Cicero, as an old friend of his father, took an interest in him and seven of his letters (*Ad Familiares*, ii, 1–7) are addressed to Curio.

See T. Rice Holmes, *The Roman Republic and the Founder of the Empire* (1923).

**CURITIBA**, the capital of the state of Paraná, Braz., is located 3,000 ft. above sea level, near the Atlantic margin of the Brazilian highlands and has a temperate and healthful climate. It is about 50 mi. W. of the port of Paranaguá, with which it is connected by a spectacular railroad passing through beautiful scenery. The city is also reached by rail, highway and air lines from other parts of Brazil. Pop. (1960) 344,560.

Curitiba was founded in 1654 as a gold-mining camp, but the ores proved unimportant. In 1854, it became the capital of the state of Paraná, and during the next 60 years it received many Italian, German and Polish colonists. Since 1940 growth has been especially rapid because of the economic development of the state as a whole. Curitiba is an important processing centre for maté, lumber and cattle. Manufactured products include paper, furniture, textiles, cement, matches and tobacco products. Many modern buildings distinguish the central business district. The city is an Episcopal see and the seat of the state university. Old and now incorrect, spellings include Curityba, Curytiba, and Corityba. (P. E. J.)

**CURIUM**, a synthetic chemical element having the symbol Cm and atomic number 96, is the seventh member of the actinide

series in the periodic system (see PERIODIC LAW; TRANSURANIUM ELEMENTS). It was the third transuranium element to be discovered—in the summer of 1944, and only a few months before the discovery of americium, the element preceding it in the periodic table. The discoverers were G. T. Seaborg, R. A. James, and A. Ghiorso, who were working at the University of Chicago. They identified the isotope  $\text{Cm}^{242}$ , which had been produced as the result of the helium-ion bombardment of a plutonium isotope,  $\text{Pu}^{239}$ , in the 60-in. cyclotron of the University of California, Berkeley. The element was named curium after Pierre and Marie Curie, by analogy with the naming of its rare-earth homologue, gadolinium, after the Finnish chemist J. Gadolin.

Curium was first isolated in the form of a pure compound (the hydroxide) of  $\text{Cm}^{242}$ , produced as the result of the neutron irradiation of  $\text{Am}^{241}$ , by L. B. Werner and I. Perlman at the University of California, Berkeley, in 1947.  $\text{Am}^{241}$  absorbs neutrons to form the short-lived (half-life 16 hr.) beta-particle emitter,  $\text{Am}^{242}$ , which in turn decays to  $\text{Cm}^{242}$ , according to the reactions

$\text{Am}^{241}(n,\gamma)\text{Am}^{242} \xrightarrow{\beta^-} \text{Cm}^{242}$ . This method was the source of  $\text{Cm}^{242}$  for much early research with macroscopic quantities. For the investigation of curium in weighable amounts,  $\text{Cm}^{244}$  (half-life 17.6 yr.) has been used to an increasing extent because of its longer half-life and its availability as a result of intensive slow neutron irradiation of  $\text{Pu}^{239}$  in nuclear reactors according to the reactions  $\text{Pu}^{239}(n,\gamma)\text{Pu}^{240}(n,\gamma)\text{Pu}^{241}(n,\gamma)\text{Pu}^{242}(n,\gamma)\text{Pu}^{243} \xrightarrow{\beta^-}$

$\text{Am}^{243}(n,\gamma)\text{Am}^{244} \xrightarrow{\beta^-} \text{Cm}^{244}$ . Further neutron irradiation of  $\text{Cm}^{244}$  produces higher-mass isotopes of longer half-life which are

Isotopes of Curium

Isotope*	Half-life	Type† and energy of radiation (Mev)
$\text{Cm}^{238}$	2.5 hr.	EC (~99% est.) $\alpha$ (~1% est.) 6.50
$\text{Cm}^{239}$	2.9 hr.	EC
$\text{Cm}^{240}$	26.8 days	$\alpha$ 6.25
$\text{Cm}^{241}$	35 days	EC (99%) $\alpha$ (1%) 5.94, 5.88
$\text{Cm}^{248}$	162.5 days	$\alpha$ 6.110 (73.7%), 6.066 (26.3%), 5.965 (0.035%)
$\text{Cm}^{243}$	32 yr.	$\alpha$ 6.054, 5.987, 5.780, 5.736, plus others at 6.061, 6.005, 5.900, 5.872, 5.680, 5.767, 5.634
$\text{Cm}^{244}$	17.6 yr.	$\alpha$ 5.801, 5.759, 5.661
$\text{Cm}^{244m}$	0.035 sec.	IT 1.032
$\text{Cm}^{245}$	9,320 yr.	$\alpha$ 5.36, 5.31
$\text{Cm}^{246}$	5,480 yr.	$\alpha$ 5.37
$\text{Cm}^{247}$	$1.6 \times 10^7$ yr.	$\alpha$
$\text{Cm}^{248}$	$4.7 \times 10^8$ yr.	$\alpha$ (89%) 5.054 SF (11%)
$\text{Cm}^{249}$	65 min.	SF 0.9
$\text{Cm}^{250}$	$1.7 \times 10^4$ yr.	SF

\*The symbol m placed after the mass number refers to an isomeric form of the isotope; †EC = electron capture; SF = spontaneous fission; IT = isomeric transition;  $\alpha$  = alpha particle;  $\beta^-$  = negative beta particle.

even better for use in the investigation of curium:  $\text{Cm}^{244}(n,\gamma)\text{Cm}^{245}(n,\gamma)\text{Cm}^{246}(n,\gamma)\text{Cm}^{247}(n,\gamma)\text{Cm}^{248}$ .

Thus curium, formed as the result of neutron irradiation, consists of a mixture of isotopes. Since the isotopic composition is variable, depending on the source, no completely logical assignment of atomic weight is possible.

The early investigations of the chemical properties of curium were performed with the tracer technique utilizing  $\text{Cm}^{242}$ . This was followed by work with weighable amounts of the short-lived  $\text{Cm}^{242}$ , which is very difficult to use; and then with the longer-lived  $\text{Cm}^{244}$ . More and more, the even longer-lived heavier isotopes have been used. This work has demonstrated that curium exists almost exclusively in oxidation state III (faint yellow colour) in aqueous solution, as expected on the basis of the stable configuration of the half-filled 5f electronic shell; i.e., the 5f<sup>7</sup> configuration.

Curium metal can be prepared by heating curium trifluoride with an alkaline-earth metal such as barium at high temperature (1,200° to 1,300° C). It is silvery in colour and has the properties of an electropositive, reactive metal. It has a hexagonal close-packed structure as determined by X-ray diffraction, with a calculated density at room temperature of 13.5 g./cc. The melting point is  $1,340 \pm 40^\circ \text{C}$ .

Most solid compounds of curium III exhibit a faint yellow colour. All of the trihalides have been prepared; they have hexagonal

structures. The sesquioxide,  $\text{Cm}_2\text{O}_3$ , with the cubic  $\text{Mn}_2\text{O}_3$ -type structure, can be prepared by heating the dioxide in a vacuum. The black dioxide,  $\text{CmO}_2$ , can be obtained by decomposing curium III oxalate in an oxygen-ozone atmosphere at 300° C and cooling in the gas stream. The monoclinic tetrafluoride, isostructural with  $\text{UF}_4$ , can be prepared by heating the trifluoride with fluorine at 400° C.

The solubility properties of curium III compounds are in every way similar to those of the other tripositive actinide elements and the tripositive rare-earth elements. Thus the fluoride and oxalate are insoluble in acid solution, while the other halides and the nitrate, sulfate, perchlorate, and sulfide are all soluble.

Curium III has no absorption bands in the visible spectrum but absorbs heavily in the ultraviolet region. In this, curium is again analogous to its homologue, gadolinium.

Adsorption and elution from columns packed with ion-exchange resins are used to separate curium from other tripositive actinide elements. Curium can be separated from the rare-earth elements by using its tendency to form strong complex ions with species such as chloride ion in connection with ion-exchange or solvent extraction separation methods.

The isotopes  $\text{Cm}^{242}$  and  $\text{Cm}^{244}$  can be used as sources of electricity through conversion of their heat of radioactive decay by thermoelectric or thermionic devices. Such power units are very compact and lightweight, and therefore admirably suited for use as long-lived power sources in space and in certain terrestrial circumstances.

**CURLEW**, the name given to several shore birds of the genus *Numenius* (subfamily Tringinae) of the family Scolopacidae. They are related to snipes, woodcock and sandpipers and have similar habits. As a group they are virtually cosmopolitan; but three of the eight species are restricted to the old world, two occur only in the new world and three are found, at least casually, in both. All are tall, stately birds, much alike in general appearance, although differing considerably in size (12–24 in.). The upper parts are brown, patterned with tawny or gray, and the underparts are buffy-white, more or less conspicuously streaked with brown. The long, slender, decurved bill (two to seven inches) distinguishes curlews from most of its relatives.

Rather gregarious and essentially terrestrial, curlews frequent mud flats, estuaries, marshes and moors, where they subsist on a variety of animal matter. As with most shore birds curlews have strong flight. They winter south of their breeding range. They nest on the ground, laying three or four pale-brown or olive eggs, speckled or boldly spotted with dark brown.

The long-billed curlew (*N. americanus*) breeds from southwestern Canada to southeastern Texas. The Madagascar curlew (*N. madagascariensis*), largest of the family, is about two feet long (including the seven-inch bill) and may have a wingspread of 42 in. The least curlew (*N. minimus*) is but 12 in. long, with a two-inch bill. Both are native to the old world, as is the slender-billed curlew (*N. tenuirostris*), which alone reaches Europe during migration. The lesser curlew, or whimbrel (*N. phaeopus*), is almost cosmopolitan; best known of its three geographical varie-

BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM  
ESKIMO CURLEW (NUMENIUS BOREALIS)

ties is the Hudsonian curlew (*N. p. hudsonicus*), which breeds in arctic America and winters south to Chile. The bristle-thighed curlew (*N. tahitiensis*) breeds in the mountains of Alaska and migrates some 6,000 miles to winter on islands in the South Pacific. The Eskimo curlew (*N. borealis*), now virtually extinct, formerly bred in abundance in arctic America and wintered on the pampas of South America. The stone curlew, or thick-knee (*Burhinus oedicnemus*), of Europe, belongs to a different family, Burhinidae.

(E. R. BE.)

**CURLING**, a winter sport similar to bowls or shuffleboard, is played on the ice. The rink is 138 ft. long by 14 ft. wide. There are two contending teams of four players, designated, as in bowls, lead, two, three and skip, or captain, each of whom delivers two stones alternately with his opponent. Which lead goes first is determined by the toss of a coin or by one throwing his broom to the other to catch, and their then placing hand over hand till one comes out on top. The stones are slid down the rink toward the tee, a fixed mark in the centre of a circle, which may be marked with a series of concentric circles or bands to aid in scoring and which is called the house. When all 16 stones have been delivered, a team scores from one to eight points according to the number of its stones that lie nearer the centre of the house than any of its opponent's. If neither side has a stone in the house, or the two opposing stones nearest the centre are equally distant from it, there is no score and a zero is posted. This constitutes an end, or inning. Play is then resumed in the opposite direction by the lead of the winning team, or rink, which is the term commonly employed by curlers. The number of ends in a match varies. Once it was as many as 17, even up to 21 for the finals of a bonspiel, or tournament. Then 12 and 14 ends became usual. With the increasing multitude of curlers, the multiplication of contending teams and the limitation of most curling to enclosed rinks with artificial ice, matches are often reduced to ten ends. In case of a tie, an extra end is played.

**Glossary.**—The following terms are used in describing the sport and are in common usage among curlers:

*Besom*, broom or brush used for sweeping (sooping) the ice.

*Bonspiel*, a curling tournament.

*Building a house*, strategy of placing a team's stones to protect each other and block opponents.

*Button*, one-foot circle around the tee.

*Chipping-the-winner*, striking a winning stone of which only a small part can be seen.

*Crampet*, a metal plate with spikes to hold it on the ice, just in front of the foot score, used as a foot brace, or hack, from which to deliver a stone.

*End*, an inning, constituting the delivery of all stones to one end of the rink.

*Granite*, curling stone.

*Hack*, a shallow depression in the ice just in front of the foot score, used as a foot brace from which to deliver a stone (see *Crampet*).

*Head*, the stones in the house after all 16 have been played.

*Hog*, a stone that fails to cross the hog line (see fig.); it is removed from the rink, unless it has struck another stone.

*House*, the 12-ft. circle around the tee.

*Pat-ld*, a stone lying on the tee.

*Pebbling*, spraying the rink with drops of hot water from a sprinkler.

*Port*, opening between two stones.

*Raise*, promote a stone toward the tee with another stone.

*Rink*, the ice on which the game is played; also a team.

*Scoop*, sweep.

*Tee*, fixed mark on the ice indicating the centre of the circle, or house.

*Wick*, to carom off a stone.

**Equipment.**—The rounded stones are about a foot in diameter, between four and five inches high and weigh around 40 lb. Curlers once had individual stones, which sometimes varied greatly. But modern practice is for clubs to have matched stones, which behave uniformly and need not be sorted out for every match and every end. Opposing teams distinguish their stones by the colour of their handles. Only a few inches of the rounded bottom of a stone touch the ice, so that it slides along readily. Though commonly called granites, they are actually made of hone (fine whetstone, used also to sharpen tools) which has a superior smoothness and texture. It takes a stone, put down with average speed, about 17 seconds to traverse the rink.

In Canada, in the province of Quebec and in the vicinity of

Ottawa, irons, weighing about 60 lb. and of smaller diameter than stones, are sometimes used.

As already implied, the curler has a broom or, in Scotland, a long-handled brush with which he may sweep ("soop") or scrub before the stone as it moves down the ice. Outdoors the chief object was to keep the ice clean and remove any obstacle brought by the wind. This factor is of less importance on indoor rinks, where, however, some dust and lint or frost may gather, or stray straws from the broom may impede the stone's progress. The ice is prepared for curling by pebbling. Pebbling forms tiny specks on the ice which slightly roughen its surface, prevent the stone from sliding too much and increase its tendency to curl or bend to the right or left. Sweeping presumably lessens the pebble and so makes the stone travel straighter and farther. Some curlers mop the ice instead of pebbling it.

**The Rink.**—In the accompanying figure of half of a rink (the other half is marked in the same way) A designates the tee, the centre of the house, the outer circle, G, has a radius of 6 ft.; concentric circles with radii of 4 ft., 2 ft. and 1 ft. also may be drawn on the ice. B designates the foot score, often marked by a slab of wood firmly embedded in the ice. C marks the back score, or line, behind which the opposing skip stands until the stone coming toward him has reached the sweeping score, F, drawn through the centre of the house, when he is at liberty to sweep it through. Otherwise, no one may sweep an opposing stone. Such a stone is out of play after it passes the back line, and should be pushed away where another stone may not be stopped on that line by it. Only those stones can count in scoring which are in the house or touch its outer circle, but stones are not out of play until they pass the line C, or touch or cross the side lines of the rink, or fail to cross the hog line, D. But a stone which strikes another lying in play remains itself in play though touching the hog line.

DIAGRAM OF HALF A CURLING RINK

**Play.**—In delivering a stone, after thoroughly cleaning the bottom to ensure an even course, a right-handed curler stands with his right foot braced against the left hack, a shallow depression made just before the foot score, or in a metal crampet laid on the ice. A left-handed curler similarly places his left foot in the depression, or the crampet to the right. Holding the handle of the stone, with his eyes fixed upon the skip's broom, placed for him to aim at, and his feet pointed toward it, he swings the stone back slowly so that its handle remains on a line directly toward the broom, and then follows through without bending his elbow and so that his hand and arm after releasing the stone point directly toward the broom. "Be on the broom" is a fundamental of curling. If the skip has signaled for an "inturn," the palm of a right-handed curler should turn to the right and be upward at the end of the stroke. For an "outturn," the hand should turn over to the left with the knuckles uppermost at the conclusion of the delivery. For the right-handed curler an inturn should curve (curl) to the right toward the end of the stone's course, and an outturn should curve to the left. The curler balances himself by holding his broom or brush in the other hand. Many slide out from the hack before releasing the stone, but they must let go of it before the sweeping score is reached. While a stone is being delivered, the courtesy and etiquette of the game require that the other players remain motionless and silent. Crossing the rink is a particularly heinous offense.

The other two members of the team stand one on either side of the rink at the nearer hog line, ready to sweep in front of the stone as soon as it crosses that line, if so directed by the skip. In the "running" game, where fast knockout shots are played

some sweepers take a running start from behind their hog line and sweep the stone at full speed in order to keep it straight in line against the opponent's stone. Sweeping within the house is the skip's prerogative, and he may sweep one of his own stones through rather than leave it in an easy position for an opponent to rest against. If a stone is "marred" by touching the broom or person of a curler, it is declared out of play, if one of his own side's stones. If it is that of an opponent, it may be placed wherever the opposing skip directs.

The lead's stones should be placed where they are difficult to dislodge or where they will obstruct the opposition's shots. Which policy to pursue may depend upon which side curls first. Normally a stone in the front circle of the house is preferable to one in the back. Some skips will not leave an opposing stone on the centre ice, even though outside the house, since it is in the way and is liable to be promoted to count against his side. Unless specifically asked to lay a guard out in front, number two should not be short on his shots, or his stone may block his own side. The skip indicates which are the opposition's stones by pointing at them with the handle of his broom; he identifies his own by pointing with the straw end. Then he signals what kind of a shot is to be played, and where the stone should go.

Variations of speed and distance are indicated by such expressions as draw weight, tee weight and back weight. Finally, making allowance for the condition of the ice and the amount which he expects the stone to curl, he places his broom for the player to aim at. After the stone has been delivered, he watches its course and directs the sweeping, either in accordance with his original intention or, if the unexpected happens, to attain some other advantageous objective. When his own turn to play comes, number three acts as skip for him.

Of common shots, the knockout (bumping an opponent's stone away from scoring position), guard (placing a stone so as to protect a teammate's stone from a knockout) and promote (bumping another stone so as to move it closer to the tee) have already been mentioned. Others are "wicking" off another stone toward the tee; coming to rest just in front of and against an opposing stone so that yours cannot be knocked out without dislodging it; drawing around a stone or stones to lie behind them nearer the tee; and "drawing through a port" or narrow space between two stones either to lie or to displace opposing stones. The point game, which is good practice and may be played by as few as two curlers, consists in attempting, both by inturns and outturns, such a variety of shots as these. For further particulars and a diagram showing how the rink should be marked for the point game, consult H. E. Weyman, *An Analysis of the Art of Curling*, 9th ed. rev., pp. 79-83 (Lévis, Que., 1953).

There is no generally accepted costume for curling. Some clubs have uniform coats or sweaters, but the most distinctive feature of the curler is the "bonnet," a plaid tam-o'shanter, balmoral or Glengarry, adorned with medals won at bonspiels and club pins exchanged with the members of opposing rinks. An essential feature is footgear that will not slip upon the ice.

**History of the Game.**—Curling, like golf, is especially associated with Scotland. But the earliest representation of it is a winter scene by the Flemish painter Pieter Bruegel (c. 1525-69), in which a band of hunters with their dogs look down upon two expanses of ice. On the farther one are skaters; on the nearer are pairs of curlers with brooms and stones with handles. The Grand Caledonian Curling club was founded at Edinburgh in 1838 "to unite curlers throughout the world into one Brotherhood of the Rink." In 1842 it became the Royal Caledonian Curling club under royal patronage. The Canadian branch of this organization was established in 1852, and in 1956 it affiliated with the Dominion Curling association. The Royal Montreal Curling club dates from 1807, however, and celebrated its 150th anniversary by a bonspiel in 1957.

In the United States, the Grand National Curling club of America was founded in New York on June 26, 1867, and was affiliated with the Royal Caledonian. Of its seven original member clubs the only surviving one is the Caledonian Curling club of New York city. St. Andrew's Golf club at Hastings-on-Hudson, N.Y., the

oldest golf club in the United States, has since its foundation and by its original constitution been devoted to curling as well as to golf. But the oldest curling club in the United States is the Orchard Lake club in Michigan, founded in 1831. United States organizations are the Midwest Curling association and the United States Women's Curling association. A magazine, *North American Curling News*, is published at Superior, Wis. The first annual U.S. men's national curling championship was held in the Chicago stadium, March 27-30, 1957. There also is curling in various countries of continental Europe and in Australia.

(L. T.)

**CURLL, EDMUND** (1675-1747), London bookseller remembered for his long quarrel with Alexander Pope, was born in 1675 in the west of England. In 1716 he published *Court Poems* and suggested that Pope was one of the contributors. Pope, in an effort to suppress this publication, met Curll at a tavern, with the result described in Pope's *A Full and True Account of a Horrid and Barbarous Revenge by Poison on the Body of Mr. Edmund Curll, Bookseller* (1716). Pope also satirized Curll in the *Dunciad* (1728). In 1716 and 1721 Curll was reprimanded at the bar of the house of lords for his publications concerning its members, and was convicted in 1725 and fined in 1728 for obscene publications—indeed, his notoriety in this respect made "Curlicism" a synonym for literary indecency. When he advertised his edition of *Mr. Pope's Literary Correspondence* (1735), Pope caused all his stock to be seized; but the book was restored to Curll, and it has been proved that Pope deviously instigated Curll's publication of the letters in order to provide him with an excuse for printing his own edition (1737). Curll died in London on Dec. 11, 1747.

See Sir Leslie Stephen, *The Life of Pope*, ch. vi (1880) and R. Straus, *The Unspeakable Curll* (1927).

**CURME, GEORGE OLIVER** (1860-1948), U.S. grammarian and professor of German, was best known for his *Grammar of the German Language* (1905, revised 1922) and his *Syntax* (1931) and *Parts of Speech and Accidence* (1935)—the third and second volumes respectively of *A Grammar of the English Language* by Curme and Hans Kurath.

Curme received most of his education at De Pauw university and the University of Michigan. He also did postgraduate work at the University of Berlin. His principal teaching posts were at Cornell college in Iowa (1886-96) and Northwestern university (1896-1933). After his retirement from Northwestern, Curme taught from 1934 to 1939 at the University of Southern California.

Curme's *Grammar of the German Language* is still, among the books by non-Germans, probably the best work in its field. His English grammars are very conservative but may be profitably consulted for detailed information, if not for up-to-date grammatical analysis and interpretation.

(D. W. R.)

**CURRAGH (CURRACH), THE**, is a plain (about 7½ sq.mi.) noted for its excellent springy turf in County Kildare, Republic of Ireland. The right of pasturage was, according to the *Liber Hymnorum* (10th century), granted by the king of Leinster to St. Bridget, who is credited with having made it a common. The downs of Kildare seem to have been an ancient meeting place. *Curragh*, meaning a "low plain," signifies a racecourse where, it is said, races were held as early as the 1st century A.D. Aenach Colmain (Curragh fair) and Aenach Life (fair on the Liffey plain) are often mentioned in the Irish annals. The deep rich pasture land with limestone underrock, based on a foundation of glacial drift, is renowned for the breeding of race horses and there are several noted training stables and studs. The Irish Derby is run there at the end of June.

The Curragh has also been known since 1646 as a military training centre, and the former British army barracks, where cavalry brigade officers led by Gen. Sir Hubert Gough offered their resignations on March 20, 1914 (see IRELAND: *History*), are now occupied by the Irish army.

**CURRAN, JOHN PHILPOT** (1750-1817), Irish lawyer and statesman, remembered both as a great advocate and as a champion of Irish liberties, was born on July 24, 1750, at Newmarket, Cork. Educated at Midleton and Trinity college, Dublin, he entered the Middle Temple in 1773 and was made a king's

counsel in 1782. He was given a seat in the Irish house of commons in 1783, but soon repudiated his patron, bought another seat and spoke vigorously for Roman Catholic emancipation and against the prevailing corruption through government patronage. Although handicapped by his small stature and an impediment of speech, he became celebrated very early for his quick and pungent wit. He displayed great moral courage in defending apparently hopeless cases and became the recognized champion of all victims of religious or political oppression although he had no Roman Catholic connections or personal religious sympathies. Between 1794 and 1803, when the French Revolution had inspired the United Irishmen to popular uprising and class warfare, Curran undertook the defense of the more important agitators, including Hamilton Rowan, Wolfe Tone and Lord Edward Fitzgerald, when they were tried for treason. When the survival of the Irish parliament became a question of bitter controversy before the Act of Union in 1800, Curran was a determined and eloquent opponent of the union. Robert Emmet's irresponsible attempt at an insurrection in 1803 involved Curran in personal suspicion because his daughter Sarah had, unknown to him, become devoted to Emmet and knew of his plans. Curran was examined before the privy council and acquitted of complicity, but his sympathies with radical nationalism had been deeply shaken.

Curran's legal practice was by no means confined to political cases, and he took a leading part, with superb forensic oratory and legal acumen, in many famous lawsuits. When William Pitt died and the Whigs took office in 1806, Curran was made master of the Irish rolls with a seat in the Irish privy council. He had hoped for higher promotion, but he held that office until 1813. In 1814 he retired to London and became a distinguished member of the group of wits, writers and lawyers which included Sheridan, Thomas Moore, Lord Byron and Robert Erskine. Curran died at Brompton, Middlesex, on Oct. 14, 1817.

See Charles Phillips, *Recollections of Curran and Some of His Contemporaries* (1818); Leslie Hale, *John Philpot Curran* (1958).

(D. G.)

**CURRANT**, a common name for certain prickly shrubs of the genus *Ribes* (which also includes the gooseberry) whose piquant juicy berries are used chiefly in jams and jellies. There are at least 100 species, natives of temperate climates of the northern hemisphere and of western South America. The Rocky mountains in North America are especially rich in species. The red currants of America and northern Europe are derived from *Ribes sativum*, of *R. rubrum* and *R. petraeum*, hardy deciduous shrubs five to six feet high, of the family Saxifragaceae (*q.v.*) and indigenous to Britain, northern and central Europe and Siberia. The black currants of Europe and Canada are all derived from *Ribes nigrum*, a native of northern Europe and of northern and central Asia. A few relatively unimportant black varieties of America are derived from *R. americanum* and *R. odoratum*, natives of North America. *Ribes sanguineum*, a native of the western coast of North America, is the flowering currant of northern Europe and *R. aureum* is the chief American flowering currant, or golden currant.

The currant seems to have been first cultivated sometime before 1600 in the Netherlands, Denmark and around the Baltic sea. Bushes were taken to settlements in America early in the 17th century; most American varieties, however, originated there. Both red and black currants are used for making tarts, pies, jams, jellies, etc. Black currants are also found in lozenges, are used for flavouring and are occasionally fermented. Currants are extremely high in vitamin C and a flavonoid substance (formerly called vitamin P) that affects the strength of the walls of blood capillaries. Great Britain grows more black currants than any other country and about ten times as many blacks as reds.

Currants succeed best in cool, moist, northern climates. Clay and silt soils are preferred. They are propagated by cuttings 8 to 12 in. long, usually taken in the autumn and set in the nursery, immediately or in spring, three to six inches apart, with not over two buds above ground. In the plantation they are set four to five feet apart in rows six to eight feet distant. Under intensive cropping, currants are planted under grapes, peaches, cherries and pears because they stand shade better than do most plants.

Currants and gooseberries are the chief agencies in the spread of the white-pine blister rust, a destructive disease of the five-leaved pines in Europe and America. The common garden black currant is the favourite host of the blister rust. Because the white pine is a very valuable timber tree, the black currant has been declared a menace and is not grown in most of the United States, and culture of currants and gooseberries has actually been prohibited in many sections (*see also* BLISTER RUST). The Viking red currant (called Red Dutch in Norway) is immune to the blister rust, as is the Red Holland variety of Germany. Crusader and Coronet, originated in Canada, are immune hybrids between a blister-rust-immune species from Siberia and the common black currant.

The currant maggot, for which there is no known control, infects the fruit so badly in parts of western North America that currants are not grown. The currant worm may defoliate the plants in the spring unless controlled. Black currants are subject to attacks of mites that destroy the unopened buds. The swollen buds should be picked off and burned.

See also GOOSEBERRY.

(G. M. D.; X.)

**CURRENCY**. In the past, this term has been variously used to include all hand-to-hand circulating media, including gold, silver and in some areas commodities such as tobacco or sugar. The most common interpretation of the term in recent years, however, has restricted its identification to bank notes, government paper money and demand deposits in banks. Thus in the United States the money supply is usually identified with the total of government-issued coins, paper money issued by the U.S. treasury department or federal reserve banks and net demand deposits in commercial banks (defined to exclude deposits of banks with other banks, cash items in process of collection and national treasury funds). When used to denote paper money only, currency has accounted for a much smaller proportion of the typical industrial nation's total money supply during recent years than it did throughout the 19th century. In the United States during the 20th century, for example, demand deposits in commercial banks have comprised approximately 80% of the nation's total money supply. (*See also* MONEY; QUANTITY THEORY OF MONEY.)

**Historical Background of Term.**—The term "currency" has been defined in many different ways since the publication of Adam Smith's *Wealth of Nations* in 1776, and there is not even now any general uniformity in its usage. Smith employed the term "common currency" to refer to all forms of hand-to-hand circulating media, and on occasion applied it specifically to coins and bank notes. This was the general interpretation of the term at the close of the 18th century and the one which, with the addition of government paper money, continued in use through the first third of the 19th century both in Great Britain and the United States.

Many writers have interpreted currency as being synonymous with "money." Apparently under the influence of the gold standard, which was adopted widely during the latter part of the 19th century and the early part of the 20th century, it was sometimes asserted that "the only real money or cash is gold." Others maintained that bank notes were not money. But as early as the 1830s numerous writers, both British and American, recognized that demand deposits, against which checks could be drawn, serve the same purpose and have the same relationship to the price level as hand-to-hand money. Many therefore included demand deposits as part of the currency. Some 80 years later (in 1911) Irving Fisher wrote as follows: "Currency includes any type of property right which, whether generally acceptable or not, does actually, for its chief purpose and use, serve as a means of exchange. Circulating media are of two chief classes: (1) money; (2) bank deposits. But while a bank deposit transferable by cheque is included as circulating media, it is not money. A bank note, on the other hand, is both circulating medium and money."

What may be viewed as an extreme extension of the meaning of the term currency is sometimes encountered. Thomas Tooke asserted in 1826 that "currency is that medium, whether consisting of gold, notes, bills, or credit, by which the purchase of commodities is effected." Nevertheless, while several other writers have also taken the position that bills and credit in all forms have the

same price-level significance as coins and bank notes, few have explicitly included them in the term currency.

While there was some reason for Tooke's position at the time he wrote, since bills were actually used as a means of payment in Lancashire, there is no justification for the inclusion of credit instruments as a part of the currency today. This is not to deny, however, the importance of their monetary significance. Such "near moneys" as government short-term securities (treasury bills), mercantile bills and in fact all high-grade liquid securities are in demand as a substitute for cash because they can be converted into cash quickly and they yield an income that is not obtained if cash itself is held.

**Quantity.**—The volume of a nation's currency at any given time depends on many factors. Among them are the nature of the country's monetary standard, the relative significance in use of its paper money when compared with commercial-bank demand deposits and coins, the confidence its citizenry has in the credit position of the government, the status of its international balance-of-payments position, the level of general business activity and the economic wealth of the community—both real and in a nominal monetary sense. This list is by no means all-inclusive and no special significance is implied in the order of the items noted.

With the exception of the United States (which has used a managed gold-bullion monetary standard since 1934), the nations of the world have remained on monetary standards of a fiat, or trust, nature since the middle 1930s. These fiat standards have permitted governments to remain free from any obligation to repay the holders of their currencies or coins in any form of precious metal such as gold. Redemption of outstanding U.S. currency has been made only in lawful money since the Gold Reserve act of 1934, such lawful money consisting of all legal-tender currencies and coins in circulation. Realistically, it must be said that the volume of currency the world over is limited by the action of governments and not by the supply of precious metals. (See also GOLD STANDARD.)

Under a gold-coin monetary standard, in which all currencies are redeemable in gold at their owners' request, it is reasonable to conclude that the volume of a nation's currency will be governed by the amount of gold held within the country for purposes of such redemption. In contrast, no such automatic restriction on currency issue is present under a fiat system. The argument is sometimes advanced that the only protection against an over-issue of currency lies in the adoption of a monetary standard with free convertibility of all currencies and token coins into gold. It is true that whenever there has been a substantial over-issue of irredeemable currencies in the past, a fiat rather than a gold monetary standard has been employed. It can be demonstrated, however, that the failure to achieve proper quantitative control of the currency issue was due to conditions other than the absence of a monetary standard associated with gold. The proposition has been widely defended since the close of World War II that the volume of currency issue within a country that will best contribute to a maximum usage of the nation's economic resources can be realized as readily under one monetary standard as another. There is nothing inherently superior about the gold standard from the point of view of its influence upon the economy. If a nation is on the gold standard there will probably be some relationship between the quantity of currency and of money, the output of gold and the price level; but it will be tenuous and uncertain at best.

In the absence of any so-called "automatic" regulator of a nation's currency supply, such as was at one time claimed for the gold standard, one must look elsewhere for the factors which determine its volume. Two examples will suffice, one for the United Kingdom and the other for the United States.

**United Kingdom.**—The currency of England and Wales is made up entirely of the circulating notes of the Bank of England (*q.v.*), although in Scotland and Northern Ireland several joint-stock banks have the right to issue notes backed by those of the Bank of England. In addition, these Scottish and Irish banks are empowered to issue a small volume of fiduciary or uncovered notes. The note issue of the Bank of England is entirely fiduciary and is placed in circulation with a backing of government securities

instead of gold. Since 1939 all gold accumulations in England have been held in the government's Exchange Equalisation account with the consequence that the Bank of England has no gold, can obtain none and must use government securities as collateral for its note issues.

The Bank of England's note-issuing functions have been legally separated from its banking operations since 1844 when the Bank Charter act was passed. To obtain currency for issue, its banking department deposits government securities with its issue department. A small gold holding is regularly shown in the bank's weekly return but it is insignificant in relation to the total volume of notes issued. Any addition to the currency supply, consequently, must be accompanied by an increase in the holding of government securities by the issue department. It is not difficult to see, therefore, that a limiting factor to increases in the currency position of the United Kingdom is the debt position of her government. This factor of public debt is as significant in the currency system of the United States as it is in the United Kingdom.

**United States.**—The U.S. government uses two agencies in the issuance of its currency—the treasury department and the 12 federal reserve banks. Quantitatively speaking, the currency issues of the reserve banks are more significant, having filled the need since 1913 for a more flexible currency supply in the hands of the public. The outstanding issues of the treasury are composed in large measure of carry-overs from the years prior to 1913 when the Federal Reserve act was passed. The federal reserve system (*q.v.*) was, in fact, created for the purpose of providing a flexible currency supply so that the periodic financial crises which had plagued the nation for many years could be avoided. Sufficient flexibility was sought by tying the issue of the new federal reserve notes directly to the needs of business. The use of short-term business and agricultural paper as collateral for the notes was introduced with the commercial banks being empowered to rediscount or borrow at the federal reserve banks by means of such credit instruments. Subsequently, the list of commercial-bank assets acceptable at the federal reserve banks as collateral for federal reserve note issue was extended. Gold, gold certificates and finally debt obligations of the federal government were added. As a safeguard against overissue of the notes the law provides that the reserve of the issuing federal reserve bank must equal the value of the notes it issues. Furthermore, the federal reserve system's board of governors may require additional collateral when, in the opinion of the board, it is needed.

**History of Currency Theories.**—Before the advent of commercial banking in Great Britain in the 17th century, paper-money currency did not exist in that country. The hand-to-hand media of exchange consisted exclusively of coins. In the American colonies, however, numerous experiments were made with various types of paper money. Following the development of banking in Great Britain and the establishment of the first commercial bank in the United States in 1782, bank notes became an important element in the currency of both countries. (See also BANKING.)

From about 1830 to 1844 (during which period the term "currency" was generally interpreted to include coins as well as paper money), there was much controversy in Great Britain between the so-called currency and banking schools. Members of the currency school held that the existing mixed metallic and paper (bank-note) currency should vary with exports and imports of gold precisely as would a purely metallic currency. By this they meant that an outflow of gold should immediately cause a contraction of the currency and thus reduce prices, or contrariwise with an inflow. Thus international equilibrium would be automatically restored. Failure so to control the stock of currency, they asserted, would permit the banks to continue to expand their loans and, consequently, the quantity of circulating medium after an outflow of gold had set in. This development, they believed, would eventually lead to an undermining of the reserve position of the banks, and therefore to a violent contraction and commercial "revulsion." Most of these writers either ignored or greatly underestimated the importance of deposits as an element in the stock of money.

The banking school saw the influence of bank deposits more clearly, and contended that control of the currency alone would

not achieve the result desired by their opponents. In addition they denied that an immediate contraction of the stock of money was to be desired upon the beginning of an outflow of gold. International gold movements frequently were due, they asserted, to the requirement of making some specific and limited payment, rather than to a fundamental condition of disequilibrium. To contract the currency, they claimed, would be unnecessary in these cases and would needlessly worsen domestic business conditions. Moreover, they held that the banks could not unduly expand the quantity of money because they were controlled by the "needs of business." This latter doctrine is still debated but appears to have no foundation in theory or history.

In the political field the currency school won the argument; and the note-issuing privilege of the banks was severely limited by the Bank Charter act of 1844. In its economic aspects, however, the difference of opinion has not yet been satisfactorily resolved. There is in truth a difficult problem of public policy presented when an outflow or inflow of gold takes place. It may or may not be the consequence of a fundamental condition of disequilibrium; if it is, the international position then requires a change in the domestic price level and a shift of production from domestic to international commodities, or the contrary, depending upon the direction of the gold flow. In any case the change in the stock of money causes an unwelcome disturbance of domestic economic affairs. If it involves a reduction in domestic prices, as could be the case when the flow of gold is outward, a considerable amount of unemployment may develop.

In the United States there arose contemporaneously a point of view quite similar to that of the currency school in England. Many writers contended that the currency should consist only of "hard" money, that is, coin. Nevertheless, partly because the federal government was then supposed not to have the constitutional authority to interfere with the issuance of notes by state-incorporated banks, no legislation comparable with the Bank Charter act was passed in the United States. However, the Independent Treasury act of 1846 provided for maintaining governmental subtreasuries for keeping the funds formerly deposited in various banks. This act also required the treasurer to accept and to pay out only coin. It was believed that the proportion of hard money to bank notes would thus be increased and the act may have had some slight influence in that direction.

No important legal limitation of the privilege of note issue was instituted in the United States until the passage of the National Bank act in 1863 and of the act of 1865. The former act provided for incorporation of national banks that might issue notes, but only against the security of federal government bonds. The latter act levied a tax of 10% per annum on the note issues of state-incorporated banks. The intent and effect of this tax was to eliminate entirely the notes of the state banks.

The currency of the United States was made yet more complicated by issue of the U.S. notes known as greenbacks (*q.v.*) during the Civil War and of gold and silver certificates, the former appearing in 1866 and the latter in 1880. As noted earlier, federal reserve notes were provided for in 1913 and after that date they became the major form of currency.

The general circulation of gold coin and gold certificates was discontinued in 1934 and the quantity of silver certificates greatly increased after that date because of the Silver Purchase act of that year. The privilege of national-bank note issue was discontinued in 1935.

In Great Britain the composition of the currency also changed after 1914, although it was not so complicated as in the United States. The issue of currency notes by the treasury was authorized at the outbreak of World War I, and the volume of these notes rose rapidly to a maximum of approximately £320,000,000 in Dec. 1920. Gold coins disappeared from circulation. The issue of the Bank of England also increased during these years but its quantity did not become so great as that of the currency notes.

The Currency and Bank Notes act of 1928 amalgamated the currency notes and the Bank of England issue by making the outstanding currency notes an obligation of the bank and transferring to the latter an equal amount of assets.

**CURRENCY, PRIMITIVE.** Among peoples of primitive culture is found a strange diversity of objects commonly termed "money" or "currency." These are of two main kinds, one comprising articles of practical use, the other those of which the primary purpose is ornament. The rock salt of Ethiopia, the hoes of the Dinka and Shilluk of the upper Nile, the iron and cloth of central and west Africa, the brilliant red feather bands of Santa Cruz, the dentalium shell strings of California and British Columbia, the wampum of the eastern American tribes, the tridacna-shell armlets and large stone axe blades of eastern New Guinea, the sperm-whale teeth of Fiji and the *fê* or "millstone money" of the Caroline islands have all been termed "money." Certain of these things are currency in the true economic sense; others have been dubbed so through loose definition of terms and use.

Well known among "native money" are the strings of shell disks

BY COURTESY OF (UPPER LEFT AND LOWER LEFT) CHASE MANHATTAN BANK MUSEUM OF MONIES OF THE WORLD; (UPPER RIGHT AND LOWER RIGHT) THE TRUSTEES OF THE BRITISH MUSEUM; (CENTRE LEFT) THE MUSÉE ROYAL DE L'AFRIQUE CENTRALE, Tervuren

(UPPER LEFT) RED FEATHER BANDS, SANTA CRUZ; (UPPER RIGHT) KISSI PENNY, IRON ROD CURRENCY, SIERRA LEONE, AFRICA; (CENTRE LEFT) CYPRAEA MONETA, COWRIE SHELL MONEY OF THE ZANDE TRIBE, REPUBLIC OF THE CONGO, AFRICA; (LOWER LEFT) *FÊ*, MILLSTONE MONEY OF THE YAPSE, CAROLINE ISLANDS; (LOWER RIGHT) DIWARA, NASSA SHELLS THREADED ON STRIPS OF CANE, NEW BRITAIN

so characteristic of the Melanesian islands, as the *diwara* of New Britain, the *rongo* of Malaita or the *sapisapi* of east New Guinea. Much work is involved in their manufacture, and their value varies according to their length and colour. Red disks are worth more than white, the shell from which they are obtained being more rare. These strings, whether in coils or made up into necklaces, form most important items of wealth to the native and pass freely from hand to hand in settlement of social obligations.

But according to precise terminology such objects can hardly be correctly described as currency or money. In any economic system, however primitive, an article can only be regarded as true money when it acts as a definite and common medium of exchange, as a convenient stepping-stone in obtaining one type of goods for another. Moreover, in so doing it serves as a measure of values, allowing the worth of all other articles to be expressed in terms of itself. Again, it is a standard of value with reference to past or future payments, while as a store of value it allows wealth to be condensed and held in reserve. Strings of shell disks and similar articles are certainly a form of condensed wealth and act as a store of value. But they do not consistently perform any other function of money. They may pay for canoes or be traded against one another, but they do not facilitate everyday exchanges, as those of food or implements, nor are market values of other commodities expressed in terms of them. The use of such articles is largely ceremonial; individual pieces often have names and unique histories, and are connected with the fortune of special persons and clans. In general, the economic system of the Pacific island native, considered apart from the effects of white contact, has not been shown capable of accommodating and utilizing a full-fledged circulating medium in its system of production and exchange; references to native "money" or "currency" therefore cannot be accepted at face value.

With African tribes the case is different. The use of hoes or cattle as true money is dubious, but it is clear that such objects as iron bars (often in the form of conventionalized spearheads or knives), cowrie shells, salt and cloth serve as definite media of exchange and as common measures, standards and stores of value. This may be due to external influence, particularly to that of Arab traders. The cowrie (*Cypraea moneta*) is one of the most striking forms of native currency. Ranging in west Africa from the Sahara to the Gulf of Benin, taking in the whole basin of the Niger-Benue, and including also the upper Congo-Lualaba area, its economic sphere centres especially in Tombouctou (Timbuktu), the district of the middle Niger and the country around Lake Chad. Sometimes the shells are strung on a cord, sometimes kept loose in a leather bag, and transactions of all kinds, from simple village marketing to buying and selling on a large scale, are accomplished through this medium. In recent times the cowrie has often served as the small change for a European currency. With the change in economic conditions and ideas consequent upon the arrival of the white man, objects previously not employed as actual currency may begin to extend their function and assume that position.

**CURRENT BALANCE**, or current weigher, measures an electric current by balancing the force of attraction or repulsion between two or more coils which carry the current against the force of gravity on a known mass. In the current balance credited to Lord Kelvin a coil suspended from one pan of a balance and carrying the current in a clockwise direction is repelled by the upper fixed coil in which the current is counterclockwise and attracted by the lower coil in which the current is clockwise. The resulting force on the moving coil is balanced by adding a small weight to the opposite pan. The current in absolute amperes is computed from the force on this weight, the number of turns of wire on the coils, their radii and their distance apart.

The current balance is now used only by national standardizing laboratories for determining the ratio between the absolute ampere and the international ampere, the latter being the unit in which instruments for measuring electric current are certified. In both England and the United States, 1 International ampere = 0.999835 absolute ampere. See INSTRUMENTS, ELECTRICAL MEASURING.

(H. L. Cs.)

**CURRICULUM:** see EDUCATION, HISTORY OF: *National Systems*.

**CURRIE, SIR ARTHUR WILLIAM** (1875-1933), Canadian soldier and educationist, the first Canadian commander, from 1917, of Canada's overseas forces in World War I, was born at Napperton, Ont., on Dec. 5, 1875. He was educated at the Strathroy Collegiate institute and taught school in British Columbia before he went into business in Victoria, B.C., and became the senior partner in a real estate firm. Having enlisted in the militia, he rose from the ranks to command the 5th Canadian garrison artillery, with the rank of lieutenant colonel. When World War I broke out in 1914, he was given command of the Vancouver Highland battalion in the First Canadian contingent. In 1915 he was given command of a brigade, with the rank of brigadier general; in 1916 he succeeded to the command of the first Canadian division, with the rank of major general; and in 1917 he became the commander of the Canadian corps, with the rank of lieutenant general. On his return to Canada after the war he was appointed inspector general of the Canadian militia. In 1920 he accepted the position of principal and vice-chancellor of McGill university, Montreal, a post he retained until his death in Montreal on Nov. 30, 1933. He was created companion of the Bath in 1915, knight commander of St. Michael and St. George in 1917, knight commander of the Bath in 1918, and knight grand cross of St. Michael and St. George in 1919. He received honorary degrees from 17 universities in Canada, the United States and Great Britain.

See Hugh M. Urquhart, *Arthur Currie* (1950). (W. S. W.)

**CURRIE, SIR DONALD** (1825-1909), British shipowner and politician, founder of the Castle line of steamers between England and South Africa and later head of the amalgamated Union-Castle line, was born at Greenock, Scot., on Sept. 17, 1825. Joining the newly started Cunard steamship line, Currie was appointed agent at Le Havre and Paris in 1849, and returned to Liverpool to the company's head office about 1856. In 1862 he established the Castle line of sailing ships to Calcutta, and ten years later the Castle line to South Africa. From 1876 the South African mail contract was divided between the Castle and Union lines, until, after intense rivalry, they were amalgamated in 1900.

Because of his intimate knowledge of South African conditions Currie was entrusted by the British government with certain negotiations concerning the Kimberley diamond fields, and was also concerned with the restoration of the Transvaal to the Boers. Entering politics, he was returned to parliament in 1880 as a Liberal member for Perthshire, and from 1885 to 1900 represented West Perthshire as a Liberal Unionist.

In 1881 Currie was knighted. He died at Sidmouth, Devon, on April 13, 1909.

(H. C. C. D.)

**CURRIER & IVES**, U.S. lithographers, whose lively prints of 19th-century American life are collected and often used to invoke their period. **NATHANIEL CURRIER** (1813-1888) was born in Roxbury, Mass., on March 27, 1813. He set up business in New York in 1834. **JAMES MERRITT IVES** (1824-1895), born on March 5, 1824, in New York city, joined Currier as a bookkeeper in 1852 and became his partner in 1857. Ives had a flair for selecting popular subjects, such as "The American National Game of Baseball" (1867). The firm sold retail (some by mail order) and wholesale, and had distributors in many cities including London. Prints were hand-coloured by a dozen or more women in an assembly-line manner; larger ones were sent out to young artists, among them Louis Maurer, Thomas Worth and A. F. Tait. Three sizes were advertised: small folio (about 8 x 11½), 15 cents to 25 cents each; medium folio (about 12 x 17), 35 cents to 75 cents each; and large folio (about 20 x 28), \$1.50 to \$3 each. Over 7,000 titles were published between 1840 and 1890. Currier died on Nov. 20, 1888, and Ives on Jan. 3, 1895. The firm continued

until 1907. The most popular prints are winter scenes, scenes from the Mississippi, town views, clipper ships, steamboats, whaling, trains, sports, and flowers and fruit. Sentimental and religious subjects are less favoured. In 1924 the first auction sale of Currier & Ives prints was held in New York.

**BIBLIOGRAPHY.**—H. T. Peters, *Currier & Ives, Printmakers to the American People* (1929); J. C. Bland (comp.), *Currier & Ives, A Manual for Collectors* (1931); F. A. Conningham, *Currier & Ives Prints: an Illustrated Check List* (1949).

**CURRY, JOHN STEUART** (1897–1946), U.S. painter, whose art reflects the social and aesthetic values of the depression decade of the 1930s, was born on Nov. 14, 1897, on a farm near Dunavant, Kan., of stanch Scotch-Irish Presbyterian parents. He studied art at the Kansas City Art institute and the Art Institute of Chicago. In 1918 he attended Geneva college, Beaver Falls, Pa., but left to become a free-lance illustrator, particularly of western stories. He gave up illustration in 1926 to spend a year of study in Europe. On his return he won recognition as one of the nation's foremost artists with "Hogs Killing a Rattlesnake," "Baptism in Kansas," "The Tornado" and others. His style revealed a new expression of the tremendous energy of American life. His subjects were the circus, the landscape and traditions of regions in which he lived, and the spectacle of American sports. The movement of which he was a leader and which came to be called Regionalism was one of the most significant of the 1930s, and included Thomas Benton, Grant Wood and many others. Curry executed several important murals, among them those for the department of justice in Washington (1936–37) and those for the state capitol building in Topeka, Kan. (1938–40), which reflected the activities of the abolitionist John Brown.

Curry taught at Cooper union in New York (1932–34), at the Art Students' league (1932–36), and was artist in residence at the University of Wisconsin (1936) until his death at Madison, on Aug. 29, 1946. (L. E. S.)

**CURTAIN**, a piece of cloth or similar material suspended by the top so that it may be withdrawn sideways, commonly used as a screen or hanging to regulate admission of light at windows and to prevent drafts from door or window openings. Curtains arranged to fall in ornamental folds may be called drapery, and "drapery" also may be used to describe folds of cloth covering the human body. Since ancient times drapery has been used by artists as background to enhance the human form and to add interest to portraits; thus, during the Renaissance Carlo Crivelli, like many other artists of the period, posed the Madonna and Christ Child in front of a curtain of figured cut-pile velvet, and later Sir Anthony van Dyck established for his patrons standard poses in front of voluminous theatrical curtains, establishing a persistent portrait fashion. Though this article is concerned largely with France and England, all the countries of Europe, as well as Russia and America, interpreted the major style trends described and developed them along national or regional lines.

The history of curtain design is revealed in works of art over the centuries. Though evidence in paintings of ancient times is slight, from the beginning of the Christian era use of drapery is widely illustrated in wall mosaics, carved stone or ivory reliefs and illuminated manuscripts, showing how and where curtains were used, and actual fragments of textiles, especially tapestries, are preserved in tombs and churches. Mosaics of the early Christian period show curtains suspended from rods running across arches, and in medieval illuminated manuscripts curtains are knotted or looped up at doorways. In a manuscript of about 983, in the Trier Municipal library, the pope is represented as seated in a cubicle of white curtains with elaborate borders, while a green curtain with pink and gold edge is hung from an arch. Religious paintings often show curtains used to enclose or separate dining or sleeping areas. Gothic manuscripts show that interior walls, including window and door openings, were hung with movable tapestries or with embroidered, painted or woven cloths. By the 16th century such hangings were stretched on the walls above the dado

to form continuous pictures of mythological or scriptural subjects.

**Renaissance.**—Until the close of the middle ages, windows were covered with utilitarian wooden shutters or a heavy cloth, but beds were curtained on all sides and covered with a tester, which, suspended from the ceiling by cords, provided a feeling of colour and warmth. Privacy in a bedchamber is a relatively modern idea, and beds during this period did not stand in separate rooms; they were used as couches and seats by day, with the curtains neatly looped up in the form of a bag, as seen in the 15th-century marriage portrait of the Arnolfinis by Jan van Eyck and the "Annunciation" by Rogier van der Weyden. Italian paintings of the late 15th century show carved and painted bedsteads. Surviving in the north, from about a century later, are wooden beds intended to be placed in alcoves (and faced as part of the room woodwork) or in the corner of a room (with two sides and the top paneled) or made like a box with a half-canopy of carved wood. All were furnished with curtains and valances made of rich velvets and damasks with fringe or appliquéd scrollwork designs. In 1590 the inventory of the household possessions of Lord Lumley (1534?–1609) listed for his three houses (England): "sutes of hangings of arras, sylke and tapistre, Turkey carpettes of sylke, carpettes of velvet for tables and wyndowes, coveringes and Quylites of sylke, Quissshins of clothe of gold, velvet and sylke." Dutch paintings of the 17th century reveal the interiors of simpler dwellings in which windows are shaded with single half- or full-length curtains and the fireplace hood is decorated with a fringed cloth or piece of needlework. Beds in these humbler rooms are dressed with plain fabrics, some of them undoubtedly homespun and home woven. At least in northern climates woolen cloth was probably preferred for bed curtains.

**Baroque.**—During the reign of Louis XIV the major centre of artistic innovation shifted from Italy to France. The Royal Academy of Painting and Sculpture was founded, and the Gobelins works established, serving not only as a manufactory but also as a school for all branches of the decorative arts. Under the direction of Charles le Brun, Louis XIV's palace at Versailles and other royal seats were decorated in the greatest possible magnificence. Much of the ritual and pomp of court society centred around the state bedchamber of the monarch, where, before 1689, silver furniture, including a balustrade around the bed, was complemented by bed hangings laden with threads of silver and gold. The bed furniture consisted of layer upon layer of curtains, valances and counterpanes. The posts were entirely sheathed with fabric and capped with ostrich plumes. Drapery also figured at times of mourning, when state bedrooms were draped in black or purple—indeed, such hangings were available for hire.

Princes all over Europe sought to emulate Louis XIV's court and high style of decoration. Among the designers who made this an international style was Daniel Marot, a Huguenot closely associated with a corps of Parisian artists and craftsmen working on royal commissions, who fled to Holland in 1684 in anticipation of the revocation of the Edict of Nantes. Marot's engraved designs for William, prince of Orange, and later for William and Mary of England, include many room interiors, curtain designs and several massively draped beds of fantastic invention. The upholsterer was responsible for the fabrication of these designs, which often included valances and headboards of carved wood covered with cloth and bedecked with tassels, fringe and galloon. An account of the furnishings of a room at Hampton Court, prepared for the prince of Wales in 1715, describes a "standing bed

BY COURTESY OF THE HENRY FRANCIS DU PONT WINTERTHUR MUSEUM

FIG. 1.—CURTAIN DESIGN FOR STATE BED BY DANIEL MAROT, AMSTERDAM; c. 1707

of State all compleat, the furniture of a Crimson Damask and a counter paine of the same and two pair of window curtains, cornishes and vallances, two arm'd. chairs, eight square stools, all stuffed and covered, the damask as the bed and all trimmed with a rich arras silk lace [braid] suitable and a case curtain to the bed of Crimson taffaty."

A little later many of William Hogarth's satirical prints showed curtains with scalloped, stiffened valances and applied scrolls of braid in contrasting colour. Other indications of the importance of drapery in this age are to be found in the elaborate sculptured tomb figures shrouded by curtains and palls of such realism that the textures of fur and satin can almost be identified. Countless *trompe l'oeil* wall and ceiling decorations show costly fabrics spilling over balustrades and billowing around columns.

**Rococo.**—The next European style to be developed, during the reign of Louis XV, was the rococo, with its playful decoration, pierced shells and frets, outward-flowing curves, restless movement, asymmetry and exotic flavour. The style was pre-eminently suited to interior decoration. Bed and matching window curtains were designed in a wide variety of fanciful forms, laden with ribbons, cords, braid, tassels and bows. The engraved work of François de Cuvilles, who helped introduce this style to southern Germany, shows beds designed to be placed lengthwise in an alcove lined with fabric to match the bed hangings. Bright yellow and silver are typical of the colours he chose for the Amalienburg, a hunting pavilion of the princes of Bavaria near Munich, considered a rococo masterpiece. Thomas Chippendale, whose name is synonymous with rococo in England, published in *The Gentleman and Cabinet Maker's Director* (1754) designs for beds in the Chinese or Gothic taste, as well as for field, dome, canopy and state beds. His "cornice for a Venetian window," his sofas and dressing tables canopied with overdrapes are characteristic of the upholsterer's art in the mid-18th century. Contemporary documents reveal the furnishing fabrics of this period—silk damask and patterned velvets in strong colours were used *en suite* for state rooms, but less expensive, strong woolen fabrics stamped with damask designs or pressed to give a moire effect were more generally used. For bed hangings and upholstery, needlework, both domestic and imported from the orient, was still fashionable. Block-printed textiles in floral patterns competed with painted and dyed cotton chintzes from India, especially for the furnishing of bedrooms.

**Neoclassical and Romantic.**—Soon after the middle of the 18th century Robert Adam's designs for interiors and decoration, based in large part on classical ornament, became popular in England, soon sweeping over the continent and to America as well. Adam in some cases designed not only the building and ornamentation of rooms, including elaborate plasterwork ceilings and often matching carpets, but also the furniture, lighting fixtures, hardware, drapery and colour schemes. Although the sources of his design are to be found in ancient art, he introduced a new vocabulary, harmonious and subtle, which influenced designers throughout Europe, who were ready to give up the fanciful and extravagant rococo fashion. The ornament of this lighter, more delicate and refined style consists principally of urns, arabesques, paterae, scrolling leaves or rinceau bands, garlands, swags and husks. In the arrangement of rooms, as in the disposition of veneered panels on furniture, Adam shows his mastery of invention in contrasting geometric shapes, whether lozenge, circular, rectangular or octagonal. Drapery, as used by Adam, provided contrast of texture and colour to the rich woods he employed. Bookcases with short festoons hung at the top, skirts of tables petticoated with swags, and upholstered sofas decorated with extra loops of material, often of a contrasting colour, are to be found in his designs. Indeed, wood inlay and carving often take on the form of drapery. Followers of his style in England were Thomas Sheraton and George Hepplewhite.

In the early 19th century the Directoire and Empire styles in France and the Regency in England had in common a continued interest on the part of architects and designers in archaeological discoveries and adaptations from ancient works, especially Greek but also including Egyptian. The growing romanticism led to other new fashions inspired by styles remote in space, as Indian

and oriental, or in time, as Gothic. The tops of single windows were ornamented by naturalistic carved and gilded birds, leaves or bunches of grapes that held up the drapery. Bays of several full-length windows were united by a continuous pelmet of carved and gilded wood and a stiff valance with separate curtains falling to the floor. Plain, light-coloured silks were preferred, since they could be hung to good effect in swags and loops; depending ornaments were made of turned wooden buttons and spools covered with silk thread and netted together in a deep edging. With these rich draperies, curtains of fine white material with embroidered borders were hung next to the windows to diffuse the light (now called glass curtains). Four-post, French, tent and field beds were all lavishly draped, often in chintz designed in light floral patterns.

**Victorian and Modern.**—In the Victorian age, eclecticism was carried further, with many revivals of earlier styles. Voluminous window curtains were suspended by rings from heavy brass rods. Doors and windows were smothered with curtains and portieres, both of which further confined the already cluttered rooms, busy with floral and scroll patterns on the walls, carpets and upholstery, as well as on innumerable bits of needlework.

BY COURTESY OF THE HENRY FRANCIS DU PONT WINTERTHUR MUSEUM

FIG. 2.—DESIGN FOR WINDOW CURTAINS, FROM THOMAS SHERATON, THE CABINET-MAKER AND UPHOLSTERER'S DRAWING-BOOK, 3RD EDITION, LONDON: 1802

Beginning about the middle of the 19th century, the introduction of new building materials led to a rapid change in architecture. Covered arcades and halls were built with the entire roofs or walls of glass, held in metal frames. Windows in houses and apartment buildings as well as other structures became larger. To reduce glare and re-establish the feeling of enclosed space curtains were needed. Some mid-20th-century architects incorporated curtains as an integral part of a building in the form of concrete curtain walls designed in complex geometric patterns and "hung" outside these large expanses of glass, for ornament as well as function. Generally, however, modern draperies and curtains merely repeat 18th- and 19th-century forms in much simplified versions.

The increased use of reinforced concrete led to another 20th-century development in the erection of vast buildings with solid walls and no windows, lighted only artificially. In these, wall hangings serve important acoustic and decorative functions just as they did centuries earlier in covering rude masonry. Use of curtains to divide large open spaces into separate areas also has been revived.

**CURTEA DE ARGES**, a town of Rumania, administrative centre of the Curtea de Argeş district in the Argeş region, is located 32 km. (20 mi.) N.N.W. of Piteşti. Pop. (1956) 10,673.

Between the 14th and the 16th centuries it was the capital of Walachia.

The Domneasca church is said to have been erected on the ruins of a church built by Radu Negru, legendary founder of the feudal state of Walachia. The cathedral, in the Rumanian style with Byzantine influences, was founded in the 16th century by Neagoe Basarab and repeatedly reconstructed. According to the local folklore the builder of the cathedral, Master Manole, had his wife immured alive in the structure. The Sinnicoara and Cotmeana churches, the latter built by Prince Mircea the Old who is represented on the inner and outer frescoes, also date from the 16th century. In the neighbourhood are the ruins of the 13th-century Poienari citadel. Curtea de Argeş has timber-processing and clothing factories.

**CURTIN, ANDREW GREGG** (1817–1894), governor of Pennsylvania during the American Civil War, was born in Bellefonte, Pa., April 22, 1817. After graduation from Dickinson college (Carlisle, Pa.) in 1837, he practised law and entered state politics as a Whig. When that party foundered on the slavery issue, Curtin was elected governor of Pennsylvania in 1860 by a local party friendly to the Republicans.

From the outset of the Civil War, President Lincoln had no stronger supporter among the loyal governors. In May 1861, Curtin organized a military department for his state and rushed through an act providing for a volunteer reserve corps. Following the Union defeat at the first battle of Bull Run, he at once released this picked division to the national cause. The "Pennsylvania Reserves" fought for three years with the highest distinction. On Sept. 24, 1862, he brought together at Altoona, Pa., the governors of 16 loyal states to promote the common defense and prosecution of the war. This meeting followed Lincoln's Emancipation Proclamation by two days and thus strengthened the president's hand at a crucial time. Curtin was re-elected for a second term as governor in 1863 and served until 1867.

From 1869 to 1872 he served as minister to Russia. Later, in opposition to Pres. Ulysses S. Grant, he joined the Democratic party and represented it in the U.S. house of representatives from 1881 to 1887. He died at his birthplace Oct. 7, 1894.

See William H. Egle (ed.) *Andrew Gregg Curtin: His Life and Services* (1895); William B. Hesseltine, *Lincoln and the War Governors* (1948). (E. J. N.)

**CURTIN, JOHN JOSEPH** (1885–1945), Australian statesman who was prime minister during most of World War II, was born of Irish stock at Creswick, Victoria, on Jan. 8, 1885. As a young man he became active in Melbourne trade-union affairs and suffered imprisonment for campaigning against W. M. Hughes's conscription policy. In 1917 he was appointed editor of the *Westralian Worker*; his success was rewarded by election to the federal parliament in 1928. Defeated in 1931, he returned to parliament in 1934 and was rather surprisingly elected leader of the Labor party, then in opposition, in 1935. The next years were spent in a crusade to heal the divisions within the party caused by the strains of the 1930s. With this effected, Curtin was able to lead a united party into office in Sept. 1941, when his political opponents were unable to form a government. From the outbreak of World War II he had steadily refused to contemplate entering a coalition, and in the event this doubtless helped him establish a powerful government. The general election of 1943 gave Labor an unprecedented victory. As prime minister, Curtin devoted himself to the all-important task of bringing Australia safely through the war. To this end he imposed very strict controls over national manpower and resources. He clashed with Winston Churchill by withdrawing Australian troops from the middle east, but his most controversial action was his appeal to the U.S. as Australia's chief protector, Great Britain's traditional role, when the Japanese had entered the war and were advancing southward. He died at Canberra on July 5, 1945, just as the war was coming to a close. Already his government had projected the neo-Keynesian welfare-state policies which characterized Australia during its period of rapid postwar growth.

Curtin lived under intense nervous strain and tended to veer from extreme to extreme, from Roman Catholic belief to agnosti-

cism and from pacifism to war leadership. Few politicians, however, have achieved their stated aims so completely.

See Alan Chester, *John Curtin* (1943).

(O. M. R.)

**CURTIS, CHARLES** (1860–1936), U.S. lawyer, congressman, and vice-president of the U.S. during the administration of Herbert Hoover, was born on Indian land later included in North Topeka, Shawnee County, Kan., on Jan. 25, 1860.

His mother was half Indian, and his early youth was spent with the Kaw Indian tribe. He received a common school education, studied law, and was admitted to the bar in 1881. He began practice in Topeka and served as county attorney of Shawnee County, Kan. (1884–88).

Entering politics, he was elected a Republican representative in Congress in 1893, serving continuously until 1907 when he was elected U.S. senator. Unsuccessful in his candidacy for reelection in 1912 he was, however, elected to the Senate for the term beginning March 4, 1915.

Curtis served as Republican whip of the Senate (1915–24) and majority leader (1924–29). At the Republican national convention in 1928 he was nominated for the vice-presidency on the ticket with Herbert Hoover (even though he had opposed Hoover's nomination) and the two men were elected by the overwhelming majority of 444 to 87 electoral votes. Curtis was renominated with Hoover in 1932, but they were defeated in the November election. Curtis returned to the practice of law in Washington, D.C., where he died on Feb. 8, 1936.

He married Anna E. Baird on Nov. 27, 1884. They had three children, Permelia, Harry King, and Leona.

**CURTIS, CYRUS HERMANN KOTZSCHMAR** (1850–1933), U.S. philanthropist and publisher, was born in Portland, Me., on June 18, 1850. As early as 1863 he began publishing in Portland a local weekly called *Young America*. When fire destroyed his plant, he moved to Boston, Mass., where he worked as a messenger, an advertising solicitor and as publisher of *The People's Ledger*, a magazine. He moved to Philadelphia, Pa., in 1876 and continued there the publication of the magazine. In 1879 he founded *The Tribune and Farmer*, from the women's section of which he formed a new magazine, *The Ladies' Home Journal*. In 1890, Curtis organized the Curtis Publishing company. Seven years later he purchased *The Saturday Evening Post* and in 1911 *The Country Gentleman*. In 1913 he purchased the *Philadelphia Public Ledger* and a year later began publication of the *Evening Public Ledger*. He bought the *Evening Telegraph* for its Associated Press membership, which he transferred to the *Evening Public Ledger*. Later he purchased the *Philadelphia Press* and the *North American*, both morning newspapers, and merged them with the Curtis papers. In 1924 he obtained possession of the *New York Evening Post*; in 1930, the *Philadelphia Inquirer*. He died on June 7, 1933.

**CURTIS, GEORGE TICKNOR** (1812–1894), prominent U.S. constitutional lawyer and historian of the mid-19th century, author of many legal treatises and several biographies, was born in Watertown, Mass., Nov. 28, 1812. Curtis graduated from Harvard college in 1832, taught for a time and went to Harvard law school. He was admitted to the bar in 1836 and began to practise, first in Worcester and then in Boston. In 1862 he moved to New York where he had a large practice until his retirement in 1888. He defended Dred Scott before the supreme court and appeared also in the legal tender or greenback cases. He was patent attorney for such famous inventors as Charles Goodyear, Samuel F. B. Morse and Cyrus McCormick.

In politics Curtis was at first a Whig and later, when that party died, a Democrat; he was critical of the administration during

LEWING GALLOWAY

CHARLES CURTIS

the Civil War but remained a strong unionist. He was a member of the Massachusetts house of representatives (1840–1843) and was for some time U.S. commissioner in Massachusetts. As such it was his duty in 1852 to send Thomas Sims back to slavery in compliance with the Fugitive Slave law, despite his own antislavery sentiments. He did not later accept public office but used all his leisure time and the years after his retirement for research and writing, publishing an imposing number of legal treatises, several long biographies, and in 1889 under a pseudonym a novel, *John Chambers: a Tale of the Civil War*. He died in New York on March 28, 1894.

Curtis's best known work was in the field of U.S. constitutional history. This work, written from the classical Federalist-Whig point of view, went through many editions and revisions, the last published under the title, *The Constitutional History of the United States From Their Declaration of Independence to Their Civil War*. His legal treatises include *A Digest of Cases Adjudicated in the Courts of Admiralty of the United States and in the High Court of Admiralty in England* (1839); *Treatise on the Rights and Duties of Merchant Seamen* (1841); *Treatise on the Law of Copyright* (1847); *Treatise on the Law of Patents* (1849); and a two-volume work, *Commentaries on the Jurisdiction, Practice, and Peculiar Jurisprudence of the Courts of the United States* (1854–1858). His biographical works include *The Life of Daniel Webster* (two volumes, 1870), a *Life of James Buchanan* (two volumes, 1883) and two vindications of Gen. George McClelland (1886 and 1887).

(A. F. Tr.)

**CURTIS, GEORGE WILLIAM** (1824–1892), U.S. author and editor and leader in civil service reform, was born in Providence, R.I., on Feb. 24, 1824. Early in life he spent two years as a boarder at the Brook Farm community and school. After living in New York and in Concord, Mass., for two years, to be near Emerson, he traveled in Europe, Egypt and Palestine. In 1850 he returned and joined the *New York Tribune*, to which, as the *Courier and Enquirer*, he had sent some letters from Europe. He became a popular lecturer and published *Nile Notes of a Howadji* (1851) and *The Howadji in Syria* (1852). As an associate editor of *Putnam's Monthly Magazine*, conductor of "The Lounger" in *Harper's Weekly* and "The Easy Chair" in *Harper's Magazine*, he wrote prolifically. Many of his essays were collected, chiefly in the *Potiphar Papers* (1853), a satire on fashionable society, and *Prue and I* (1856), a sentimental and humorous study of life.

In the period preceding the Civil War he subordinated other interests to those of national concern, beginning with a speech on current questions at Wesleyan university in 1856, and active participation in the presidential campaign. In 1863 he became political editor of *Harper's Weekly*. In succeeding years he was frequently offered nominations and appointments by the Republican party, but refused them all, until he was appointed chairman of the commission on civil service reform by Pres. Ulysses S. Grant in 1871. From then until his death he led this movement, and progress in the reform was mainly due to his sound judgment and forceful presentation of the evils of the political patronage system. In 1884 he refused to support James G. Blaine as candidate for the presidency and left the Republican party to become a typical Independent. In 1890 he was made chancellor of the University of New York. He died on Aug. 31, 1892.

See Gordon Milne, *George William Curtis and the Genteel Tradition* (1956).

**CURTIS, LIONEL GEORGE** (1872–1955), British administrator and author, advocate of imperial federation and of a world state, had considerable influence in the shaping of the commonwealth. He was born on March 7, 1872, and educated at Haileybury college and at New college, Oxford. He was called to the bar but began at once to take an interest in public affairs by making a study of the Poor law. He enlisted in the City Imperial volunteers in 1899 and fought in the South African War. His abilities as a student and administrator secured his appointment as secretary to Sir Alfred Milner, British high commissioner in South Africa, whose staff of gifted young men became known as "Milner's kindergarten." Curtis acted as town clerk of Johannes-

burg in 1901 and later filled various posts in the Transvaal government. In 1907 he resigned in order to work for the union of the four South African colonies, and began to develop his conception of a federal world order which occupied him for the rest of his life. He founded the quarterly *Round Table*, for the propagation of Liberal imperialist ideas, in 1910 and was appointed Beit lecturer in colonial history at Oxford in 1912. He published *The Commonwealth of Nations* in 1916 and was elected a fellow of All Souls college, Oxford, in 1921. After World War I, Curtis was secretary to the Irish conference (1921) and colonial office adviser on Ireland (1921–24). In 1920 he was a founder of the organization which became, in 1926, the Royal Institute of International Affairs at Chatham house, London. He also visited India and China, publishing books on both countries: *Dyarchy* (1920) and *The Capital Question of China* (1932). After 1932 he devoted himself to his major work, *Civitas Dei*, 3 vol. (1934–37), in which he described the organization of human society in a more advanced form from that of separate nations. Curtis continued to write until his death near Oxford on Nov. 24, 1955.

(J. F. B.)

**CURTISS, GLENN HAMMOND** (1878–1930), whose contribution to the development of U.S. aviation was exceeded only by that of the Wright brothers, was born in Hammondsport, N.Y., May 21, 1878. In a curious parallel to the story of the Wrights, who began as bicycle mechanics, Curtiss began his career by building motors for bicycles. In 1904 he was asked to design and build a motor for the dirigible "California Arrow." His success brought an order to provide the motor for Dirigible No. 1 of the U.S. army. In 1908, in an airplane constructed by the Aerial Experiment Association of America under his supervision, he won the *Scientific American* trophy for the first public flight of a kilometre in the U.S., at a speed of "almost 40 miles an hour." In Jan. 1911 Curtiss took off and landed on water at San Diego, Calif., a plane that he had equipped with pontoons. A demonstration for the U.S. navy the following month brought him the first contract for U.S. navy planes. His factories, expanded in 1917, supplied military planes to Great Britain and Russia as well as the U.S. Curtiss died in Buffalo, N.Y., July 23, 1930.

**CURTIUS, GEORG** (1820–1885), German philologist, whose works were fundamental to the development of Greek linguistics, was born at Lübeck on April 16, 1820. He held philological appointments at Prague, Kiel and Leipzig. From 1878 Curtius was general editor of the *Leipziger Studien zur classischen Philologie*. His *Griechische Schulgrammatik*, first published in 1852, has passed through more than 20 editions and has been edited in English. In his last works, he attacked the neogrammarian school of philology. He died at Hermsdorf on Aug. 12, 1885.

His brother, **ERNST CURTIUS** (1814–1896), archaeologist and historian, was born at Lübeck on Sept. 2, 1814. After traveling in Greece he became, in 1844, an extraordinary professor at the University of Berlin and tutor to Prince Frederick William (afterward the emperor Frederick III). In 1874 he concluded an agreement by which the excavations at Olympia (q.v.) were entrusted to Germany. Curtius died at Berlin on July 11, 1896.

His best-known work is his *History of Greece* (1857–67). His other writings are chiefly archaeological. His collected speeches and lectures were published under the title of *Altortum und Gegenwart* (5th ed., 1903 et seq.).

**ERNST ROBERT CURTIUS** (1886–1956), romance philologist, was the son of Ernst Curtius. His work was instrumental in bringing modern European literature, particularly that of France, to the attention of the German public.

**BIBLIOGRAPHY.**—See *Opuscula* of Georg Curtius, edited after his death by E. Windisch (*Kleine Schriften*, 1886–87). A full list of the writings of Ernst Curtius will be found in L. Gurlitt, *Erinnerungen an Ernst Curtius* (1902); F. Curtius, *Ernst Curtius, ein Lebensbild in Briefen* (1903); T. Hodgkin, *Ernst Curtius* (1905).

**CURTIUS, MARCUS**, a legendary hero of ancient Rome. It is said that in 362 B.C. a deep gulf opened in the forum, which the seers declared would never close until Rome's most valuable possession was thrown into it. Then Curtius, recognizing that nothing was more precious than a brave citizen, leaped, fully armed and on horseback, into the chasm, which immediately closed. The spot was afterward covered by a pond, dry by the

1st century B.C., called the *Lacus Curtius*. Alternative explanations of the name *Lacus Curtius* are given: (1) a Sabine general, Mettius Curtius, hard pressed by the Romans under Romulus, leaped into a swamp which covered the valley afterward occupied by the forum; (2) in 445 B.C. the spot was struck by lightning, and enclosed as sacred by the consul, Gaius Curtius.

See S. B. Platner and T. Ashby, *Topographical Dictionary of Ancient Rome*, p. 310 (1929).

**CURULE**, the epithet applied in ancient Rome to the chair of office, the *sella curulis*, used by the higher magistrates (and probably at one time by the king), who were termed "curule": the consul, praetor, curule aedile (*q.v.*), dictator, master of the horse, interrex and censor, and later the emperor. The chair was inlaid with ivory, had curved legs, was without a back, and could be folded. The chair was perhaps originally placed on a magistrate's chariot. A curule triumph was celebrated on a chariot. The chief municipal magistrates were also entitled to the curule chair.

(T. R. S. B.)

**CURVES**. A curve, in mathematics, is most easily thought of as the path of a point moving continuously with respect to both position and direction, except at special points where discontinuities of any kind may occur. Formerly the word *line* was used to include both curves and straight lines; in modern use it always means a straight line, and is a particular case of the more general term *curve* (see *LINE*).

A curve may also be thought of, given in its entirety, as a single infinity of points. This point of view is the one adopted by mathematicians in the study of continuous curves (see *TOPOLOGY*, *GENERAL*).

In either case, the idea becomes more definite when all the points of the curve, whether given successively or simultaneously, are regarded as obeying some sort of law. This law may be expressed by one or more equations between co-ordinates, involving certain functions of them which vanish. The curve is said to be *algebraic* or *transcendental* according to the nature of its equations in Cartesian co-ordinates. If it is algebraic, it has only a finite number of exceptional points, whereas a transcendental curve can have an infinite number (for example, see *CURVES*, *SPECIAL*), and if its equation involves one of the highly discontinuous functions known to modern analysis it may lose all or nearly all of the properties usually associated with the idea of curve.

If P is an ordinary point of a plane curve, and Q is a neighbouring point, then as Q moves closer to P, the chord PQ approaches a definite limit called the *tangent* at P. The line through P perpendicular to the tangent is called the *normal*. Three points P, Q, R of the curve determine a circle, whose limit as Q and R approach P is the *circle of curvature* at P. The more sharply the curve bends, the smaller is this circle, and the reciprocal of its radius is the *curvature* at P, and is equal to the rate of rotation of the tangent (or normal) per unit length of arc described by P. The centre of the circle of curvature is also the limit of the intersection of adjacent normals. In the immediate neighbourhood of P, to a first approximation the curve can be replaced by the tangent, and to a second approximation by the circle of curvature.

By the principle of duality (*q.v.*) a curve can also be regarded as the envelope of its tangents. The tangent can be considered to be a line moving continuously in one plane according to some law; its intersection with a neighbouring tangent has a definite limit, which is the point of contact. Thus the tangent replaces the point as the element which generates the curve, and the point of contact replaces the tangent.

**Curves in Space.**—A *twisted curve*, also called *space curve* or *skew curve*, is one which does not lie wholly in one plane. If P, Q, R, S are four neighbouring points of a twisted curve, the planes PQR, QRS are in general distinct. The limit of PQR as Q and R approach P is the *osculating plane* at P. The normal is the perpendicular to the tangent in the osculating plane, and the common perpendicular to the tangent and normal is the *binormal*. The circle of curvature (limit of the circle PQR) lies in the osculating plane; but its centre is not the limit of intersection of adjacent normals, for these, lying in different osculating planes, do not meet in general. The four points P, Q, R, S determine a sphere through

the circles PQR, QRS, the limit of whose centre is the *centre of spherical curvature* at P.

It is useful to think of the tangent, normal and binormal as a rigid frame of rectangular axes, with P as origin, moving forward and rotating as P describes the curve with unit velocity. At any moment, the angular velocity of the frame about the binormal is the *curvature*, and that about the tangent is the *torsion*; there is no instantaneous rotation about the normal.

The *degree* of an algebraic plane curve is that of its equation, and is the number of its intersections with a general line of the plane; its *class* is the number of its tangents through a general point. The degree of an algebraic twisted curve is the number of its points that lie in a general plane, and its class is the number of its osculating planes through a given point. An algebraic twisted curve has another important characteristic, the *rank*, which is the number of its tangent lines that meet a general line.

In space, the figure dual to a curve locus is a singly infinite set of planes obeying some given law. These planes form a *developable surface* (see *DESCRIPTIVE GEOMETRY*). Any plane of the set with any other one determines a line, and with any other two it determines a point.

**Forms of Equations.**—For the equation of a transcendental curve, there is often a simple expression in polar or other co-ordinates (for example, see *CURVES*, *SPECIAL*: *Euler's Spiral*). In other cases (see *Cycloid* in the same article), the simplest form gives each co-ordinate in terms of a common parameter. The parametric expression is often useful for algebraic curves also. For example, by a proper choice of a system of homogeneous co-ordinates any twisted cubic can be represented by  $x:y:z:w = 1:t:t^2:t^3$ . Still another form of expression is in terms of the length of any arc and the angle between the tangents at its extremities; this is called the *intrinsic equation*, since it depends on no frame of reference unconnected with the curve.

**Degenerations and Intersections.**—The equation of a plane algebraic curve  $k$  of degree  $n$  in Cartesian or homogeneous co-ordinates contains  $\frac{1}{2}(n+1)(n+2)$  coefficients, whose  $\frac{1}{2}n(n+3)$  ratios are the independent parameters of the curve, regarded as a member of the whole plane family of curves of degree  $n$ . Any special type of plane algebraic curve can be obtained by making restrictions on these parameters; e.g., the conditions for the three types of conic section (*q.v.*).

For certain sets of values of the parameters, the left-hand side of the equation factors, and each factor itself gives a separate curve. The product vanishes whenever any factor vanishes, and the equation is satisfied by the co-ordinates of a point on any one of these curves, and so represents their aggregate. In many cases it is convenient still to regard this as a single curve, which is then said to be *degenerate*. Thus a pair of intersecting lines is a degenerate conic. A curve which does not break up is said to be *proper*.

In the plane, any aggregate of curves can be regarded as a degenerate curve of degree equal to the sum of their separate degrees. In space this is not so unless the components satisfy certain conditions of incidence; for example, a pair of skew lines is not a degenerate conic. A conic and a line meeting it twice, and therefore lying in its plane, form a degenerate plane cubic; a conic and a line not in its plane, but meeting it once, form a degenerate twisted cubic; a conic and a line not meeting it, but meeting its plane at a point not lying on the conic, cannot be regarded as a single degenerate curve.

The common points of two curves of degrees  $n_1, n_2$  are those whose co-ordinates satisfy both equations, and their number is  $n_1 n_2$ . This continues to hold if one or both of the curves break up. Infinite curves approach one or more limiting tangents (called *asymptotes*).

**Singularities.**—The interest of any curve depends largely on its exceptional points, where the ordinary properties fail. A *singularity* or *singular point* of a curve  $k$  is a point where a unique, definite tangent does not exist. The simplest is an ordinary *double point* or *node* O, where two separate branches of  $k$  cross. Here there is not one definite tangent, but two, one belonging to each branch (see fig. 1). A moving point describing  $k$  comes to O

twice, on different occasions and in different directions. A general line  $l$ , passing near  $O$  but not through it, meets  $k$  at two points near  $O$ , one on each branch, both of which approach  $O$  when  $l$  moves so as to pass through  $O$ . If  $l$  is ultimately one of the tangents at  $O$ , three such intersections are absorbed—two on the branch touched, and one on the other.

FIG. 1.—SINGULAR POINTS

In general, the *multiplicity*  $s$  of a singular point  $O$  is the number of intersections with a general line absorbed there. Through  $O$  there are always  $s$  lines, distinct or coincident, on which more than  $s$  intersections are absorbed, and which are the tangents at  $O$ . If the  $s$  tangents are distinct, the point  $O$  is *ordinary*. If  $O$  is  $s_1$ -fold on one curve and  $s_2$ -fold on another, it absorbs just  $s_1 s_2$  of their points of intersection if they have no common tangent at  $O$ ; if they touch, it may absorb any greater number.

If any of the  $s$  tangents coincide,  $O$  is an *extraordinary* singularity. The simplest is a *cusp* of the first kind, a variety of double point which may be thought of as the limit of a loop drawn together to its node. A point  $P$  describing  $k$  continuously comes to rest at  $O$  and reverses its direction of motion; for this reason a cusp is often called a *stationary point*. The tangent at  $P$  rotates in the same sense without reversal. A cusp is analogous to the path of an engine running past catch points to rest, and backing onto another pair of rails; that is, running forward on one branch of a Y and backing up on the other.

FIG. 2.—SINGULAR TANGENTS

A set of different but corresponding singularities presents itself when a curve is regarded as an envelope. A *singular tangent* is one which does not have a unique, definite point of contact. The line singularity which corresponds to an ordinary double point is a *double tangent*, with two distinct, definite points of contact, each a simple point of the curve (see fig. 2). That which corresponds to a cusp is an *inflection*, a singularity occurring when the two points of contact coincide and the tangent meets the curve in three coincident points. A tangent describing the envelope comes to rest and reverses its direction of rotation, but a point describing the curve goes on without reversing, for the inflection is a simple point of the curve.

Every singularity of a curve which is of higher multiplicity or more complicated nature than the four elementary kinds described above is, from a great many points of view, equivalent to a certain set of distinct double points, cusps, double tangents and inflections, and can usually be regarded as the limit of this set when certain points and lines come to coincide. Thus it is seen that a triple point can arise from three double points (see fig. 3).

FIG. 3.—TRIPLE POINT AS LIMIT OF THREE DOUBLE POINTS

**Transformations; Genus.**—Two curves, whether plane or twisted, are said to be in 1-1 correspondence, or transformations of each other, or represented upon each other, if each ordinary point of either corresponds to one and only one point of the other. If the co-ordinates of the first point are given, those of the second are one-valued and therefore rational functions of these; the equations expressing this are rationally reversible, so that the co-ordinates of the first point are also expressible as rational functions of those of the second. Any curve can be thus transformed into a plane curve having no multiple points except ordinary double points, or into a twisted curve having no singular points at all.

A plane curve of given degree  $n$  cannot have more double points or cusps than  $\frac{1}{2}(n-1)(n-2)$ , or their equivalent, without breaking up. Thus the only nodal conic is a pair of lines. A proper cubic can have only one node; if it had two, the line joining them would have four intersections with the cubic, which is impossible because the curve would break up into the line and a conic through the two points. The number

$$\rho \equiv \frac{1}{2}(n-1)(n-2) - \delta - \kappa$$

by which the equivalent number  $\delta + \kappa$  of double points and cusps falls short of this maximum is called the *deficiency* of the curve, or more usually its *genus*. The fundamental property of the genus is that it is unaltered by any 1-1 transformation of the curve. If  $\rho = 0$ , the curve is *rational* or *unicursal*, and can be transformed into a line. The co-ordinates of its general point can be expressed as rational functions of a single parameter, the co-ordinate of the corresponding point on the line.

A 1-1 correspondence exists between a twisted curve  $k$  and its projection  $k'$  from any vertex  $V$  upon any plane. The singularities of  $k'$  are the projections of those of  $k$  and, in addition, a certain number of ordinary double points lying on lines through  $V$  which meet  $k$  at two distinct points. These latter points are called *apparent double points* of  $k$ , and their number is one of the essential characteristics of the curve, for it reduces the genus, being an additional number of singularities of  $k'$  whose genus is the same as that of  $k$ .

**Plücker's Equations.**—All plane curves other than lines and conics possess singularities of some sort. If they are free from multiple points, they are bound to have definite numbers of double tangents and inflections, or their equivalent in higher singular tangents. If multiple points are present, the numbers of multiple tangents are reduced. Between the degree  $n$ , class  $\kappa'$ , and the equivalent numbers  $\delta$ ,  $\kappa$ ,  $\delta'$ ,  $\kappa'$  of double points, cusps, double tangents and inflections there exists a remarkable set of relations known as Plücker's equations, by which any three of the six numbers can be calculated in terms of the other three:

$$\begin{aligned} n' &= n(n-1) - 2\delta - 3\kappa \\ \kappa' - \kappa &= 3(n' - n) \\ 2(\delta' - \delta) &= (n' - n)(n' + n - 9) \end{aligned}$$

Thus the cubic with no node is of class 6 and has no double tangents and 9 inflections; the nodal cubic is of class 4 with 3 inflections; and the cuspidal cubic is of class 3 with one inflection. The quartic with no singular points has 28 double tangents and 24 inflections.

The points of contact of the  $\kappa'$  tangents which can be drawn to  $k$  from any point  $P$  of the plane are the intersections, other than the multiple points of  $k$ , with a certain derived curve of degree  $n-1$ , called the *first polar* of  $P$  with regard to  $k$ . The first polar passes through each double point of  $k$ , meeting it in two points there, and touches  $k$  at each cusp, meeting it in three points there. The first of Plücker's equations expresses the fact that the total number of intersections of  $k$  with the first polar is  $n(n-1)$ . See also SURFACES; and references under "Curves" in the Index.

(H. P. Hu.)

**CURVES, SPECIAL.** Partly due to the study of the Greeks in pure geometry, but largely due to the influence of analytic geometry and the calculus, there have been developed a large number of special curves which have received names more or less generally accepted by mathematicians. Such curves (*q.v.*) may be classified in various ways—curves in a plane or in three-dimensional space; algebraic and nonalgebraic; alphabetically, chronologically, etc. For the purposes of the present article, it has seemed best to give an initial alphabetical list with references to the numbers of the sections, and then to arrange the sections roughly in this order: plane algebraic curves according to degree, followed by plane transcendental curves, general classes of curves and curves of double curvature. The standard equations of the curves are given in rectangular and/or polar co-ordinates when appropriate, and the general shapes of the most important plane curves considered are shown by accompanying figures.

FIG. 3.—CISSOID OF DIOCLE

$a \sec \theta - 4a \cos \theta = 2a \sin 3\theta / \sin 2\theta$ , first studied by Colin Maclaurin (1742) in connection with the problem of trisecting an angle.

7. Witch of Agnesi or Versiera,  $y(x^2 + a^2) = a^3$ , discussed and named versiera by Maria Agnesi (1748), but treated earlier by Pierre de Fermat and Guido Grandi (1703).

8. Serpentine,  $x^2y + aby - a^2x = 0$  ( $ab > 0$ ), studied and named by Newton (1701), and earlier (1692) by G. F. A. L'Hôpital and Huygens.

9. Trident of Newton or Parabola of Descartes,  $xy = cx^3 +$

$dx^2 + ex + f$ . For one form of the curve, see fig. 6.

10. Cartesian or Cartesian Ovals. The locus of a point P whose distances  $r_1, r_2$  from two points (foci, distance  $c$  between them) are connected by a linear relation  $r_1 + mr_2 = a$  is a Cartesian curve or Cartesian oval (although it consists of two ovals; fig. 7). The equation of the curve in rectangular co-ordinates may be written as  $[(x^2 + y^2)(1 - m^2) + 2m^2cx + a^2 - m^2c^2]^2 = 4a^2(x^2 + y^2)$ . When  $m \pm 1$  the locus is a central conic; when  $m = a/c$  a limaçon of Pascal results (see section 14). The curve originated with Descartes (1637) and was studied by Newton, Michel Chasles, Arthur Cayley, Gaston Darboux and others.

FIG. 4.—STROPHOID

11. Cassinian or Cassinian Ovals or Cassinian Ellipse,  $(x^2 + y^2)^2 - 2a^2(x^2 - y^2) + a^4 - c^4 = 0$ , first conceived by Giovanni Domenico Cassini (1680) in connection with the relative motions of the earth and the sun. The shape of the curve depends upon the ratio  $c:a$ . The curve may be defined as the locus of a point which moves so that the product of its distances from two fixed points (foci) A and B (see fig. 8) is a constant,  $c^2$ . When  $c > a$  the curve consists of two loops; when  $c = a$  the cassinian becomes the *lemniscate of Bernoulli* (see section 12). Those two cases, as well as two cases of  $c < a$ , are illustrated in fig. 8. The number of foci may be larger than two. By varying their number and their disposition, curves of odd shapes may be produced.

FIG. 5.—FOLIUM OF DESCARTES

12. Lemniscate of Bernoulli, first conceived by Jakob (Jacques) Bernoulli (1694), has the equation  $(x^2 + y^2)^2 = a^2(x^2 - y^2)$  or, in polar form,  $r^2 = a^2 \cos 2\theta$ .

13. Conchoid (shell form), devised by Nicomedes (c. 240 B.C.) in connection with the problem of duplication of the cube. Its equation is  $(x - b)^2(x^2 + y^2) - a^2x^2 = 0$  or  $r = a + b \sec \theta$ . Nicomedes apparently recognized the three types of the curve shown in fig. 9.

14. Limaçon of Pascal, discovered by Étienne Pascal (father of Blaise) and named by G. P. Roberval (1650). Its equation may be written as  $(x^2 + y^2 - 2ax)^2 = b^2(x^2 + y^2)$  or  $r = b + 2a \cos \theta$ . The three forms of the curve shown in fig. 10 correspond to (1)  $b > 2a$ , (2)  $b = 2a$ , (3)  $b = a$ .

15. Cardioid (see curve 2 in fig. 10), a curve whose Cartesian,

FIG. 6.—TRIDENT OF NEWTON

A number of the more common curves are treated in separate articles (see CIRCLE; CONIC SECTION; ELLIPSE; HODOGRAPH; HYPERBOLA; PARABOLA).

1. Cubical Parabola,  $y = ax^3 + bx^2 + cx + d$  or  $y = ax^2(x - e)$ , one of the canonical forms of cubics studied by Sir Isaac Newton. The special case  $y = ax^3$  (fig. 1) was used by G. W. Leibniz (1675) and (for  $a = 1$ ) by Gaspar Monge (1815).

2. Semicubical (or Neil's) Parabola,  $x^3 = ay^2$ . In 1687 Leibniz proposed to find the plane curve down which a particle may descend under the action of gravity so as to describe equal vertical spaces in equal times. Christian Huygens found that the semicubical parabola met this requirement, hence it is called an *isochronous curve*. For construction of points, see fig. 2.

3. Cissoid of Diocles,  $y^2 = x^3/(2a - x)$  or  $r = 2a \tan \theta / \sin \theta$ , a curve invented by Diocles (c. 100 B.C.) in connection with the duplication of the cube (fig. 3).

4. Strophoid,  $r = a \sin(\alpha - 2\theta) / \sin(\alpha - \theta)$  if oblique, was first considered by Isaac Barrow (1670). When  $\alpha = 90^\circ$  the strophoid is right,  $r = a \cos 2\theta / \cos \theta$  or  $y^2 = x^2(a - x)/(a + x)$ . See fig. 4.

5. Folium of Descartes,  $x^3 + y^3 = 3axy$ , a curve with asymptote  $x + y + a = 0$  (fig. 5) first discussed by René Descartes in 1638.

6. Trisectrix of Maclaurin,  $x(x^2 + y^2) = a(y^2 - 3x^2)$  or  $y^2 = x^2(3a + x)/(a - x)$  or  $r =$

FIG. 2.—SEMICUBICAL PARABOLA

polar and parametric equations are:  $(x^2 + y^2 - 2ax)^2 = 4a^2(x^2 + y^2)$ ;  $r = 2a(1 + \cos \theta)$ ;  $x = a(2 \cos \theta - \cos 2\theta)$ ,  $y = a(2 \sin \theta - \sin 2\theta)$ .

16. Tricuspid or Deltoid:  $x = a(2 \cos \theta + \cos 2\theta)$ ,  $y = a(2 \sin \theta - \sin 2\theta)$ ; or  $(x^2 + y^2 - 12ax + 9a^2)^2 + 4a(2x - 3a)^2 = 0$ . The tricuspid (fig. 11) was first conceived by Leonhard Euler (1745).

17. Simple Folium, Double Folium, Trifolium:  $(x^2 + y^2)[y^2 + x(x + b)] = 4axy^2$  or  $r = -b \cos \theta + 4a \cos \theta \sin^2 \theta$ . The simple folium, double folium and trifolium correspond to  $b = 4a$ ,  $b = 0$ ,  $b = a$ .

FIG. 7.—CARTESIAN OVALS

FIG. 8.—CASSINIEN OVALS

18. Bicorn or Cocked Hat (fig. 12). This term has been applied to two different quartics: (a)  $2y^4 - 9y^3 - 17y^2 + 125y - xy^3 - 29xy^2 + 205xy + 72x^2y - 27x^3 - 25x^2 = 0$ , named bicorn and discussed by James Joseph Sylvester (1864) and by Cayley (1867); (b)  $y^2(a^2 - x^2) = x^2 + a(2y - a)^2$ , referred to as a cocked hat in

*Educational Times*, Feb. 1896.

19. Bullet-Nose Curve,  $a^2/x^2 - b^2/y^2 = 1$ , discussed by P. H. Schoute (1885). The equation  $a^2/x^2 + b^2/y^2 = 1$  represents the Cross Curve.

20. Devil's Curve or Devil on Two Sticks (fig. 13),  $y^4 + my^2 - x^4 + nx^2 = 0$ , first studied by G. Cramer (1750).

21. Eight Curve,  $x^4 = a^2(x^2 - y^2)$  or  $r^2 = a^2 \cos 2\theta \cos^4 \theta$ , also called the *lemniscate of Gerono*.

22. Kampyle of Eudoxus,  $a^2x^4 = b^4(x^2 + y^2)$  or  $r = b^2/(a \cos^2 \theta)$ , used in connection with the problem of duplication of the cube (fig. 14).

23. Kappa Curve or Gutschoven's Curve,  $y^2(x^2 + y^2) = a^2x^2$  or  $r = a \cot \theta$ , conceived by G. van Gutschoven (c. 1662) and studied by Newton and Johann (Jean) Bernoulli.

24. Pear-Shaped Quartic,  $b^2y^2 = x^3(a - x)$ , studied by G. de Longchamps (1886).

25. Nephroid (kidney-shaped),  $(x^2 + y^2 - 4a^2)^3 = 108a^4y^2$  or  $(r/2a)^3 = (\sin \frac{1}{2} \theta)^3 + (\cos \frac{1}{2} \theta)^3$ , discovered by Huygens and Ehrenfried Walther Tschirnhausen (1678-90) and studied by Jakob Bernoulli (1692).

26. Astroid or Tetracuspid (fig. 15),  $(x^2 + y^2 - a^2)^3 + 27a^2x^2y^2 = 0$  or  $x^3 + y^3 = a^3$ , first discussed by Johann Bernoulli (1691-92).

27. Cayley's Sextic,  $4(x^2 + y^2 - ax)^3 = 27a^2(x^2 + y^2)^2$  or  $r = 4a \cos^3(\theta/3)$ , discovered by Maclaurin (1718) and studied in detail by Cayley.

28. Watt's Curve, the sextic curve generated by a point P of the side BC of a three-bar linkage AB, BC, CD, the points A and B remaining fixed while the others vary (fig. 16). If O is the mid-point of AD, and AO = a, AB = CD = b, BP = PC = c, the polar equation of the locus of P is  $r^2 = b^2 - [a \sin \theta \pm (c^2 - a^2 \cos^2 \theta)^{1/2}]^2$ ,  $\theta$  varying from 0 to  $\pi$ .

29. Pearls of Sluze,  $y^n = k(a - x)^2x^m$  ( $m, n, p$  are positive integers), studied by Baron René Française de Sluze (1657-58) and named by Blaise Pascal.

30. Lamé Curves, the family of curves  $(x/a)^n + (y/b)^n = 1$

discussed in 1818 by Gabriel Lamé (1795-1870). The curves are algebraic or transcendental depending on whether  $n$  is rational or irrational.

31. Rhodonea, curves  $r = a \cos k\theta$  or  $r = a \sin k\theta$ , named by Grandi (1723-28) because of their fancied resemblance to roses. When  $k$  is an integer there are  $k$  or  $2k$  petals of the rose curves depending on whether  $k$  is odd or even. The number of petals is finite or infinite depending on whether  $k$  is rational or irrational. Several curves corresponding to particular values of  $k$  have attracted special attention.

32. Curve of Pursuit or Pursuit Curve. If a point A describes a known curve (A), the curve (P) described by a point P is a

FIG. 12.—BICORN OR COCKED HAT

curve of pursuit if the motion of P is always directed toward A and if both A and P move with uniform velocities. The problem of the pursuit curve was first formulated and solved by Pierre Bouguer in 1732. If (A) is a straight line, the equation of (P) may be put in the form  $y = \frac{1}{2}[cx^{m+1}/(m+1)/(m-1)(cx^{m-1})]$  if  $m \neq 1$ , and  $y = \frac{1}{2}[(cx^2/2) - \frac{1}{2} \log x]$  if  $m = 1$ . A study of this curve was made by Arthur Bernhart.

33. Epicycloid and Hypocycloid. The epicycloid (hypocycloid) is the curve traced out by a point P on the circumference of a circle (B) of radius  $b$  which rolls without slipping on the exterior (interior) of a fixed circle (A) of radius  $a$ . The parametric equations of the epicycloid and the hypocycloid are respectively:

$$x = (a + b) \cos \phi - b \cos [(a + b) \phi / b]$$

$$y = (a + b) \sin \phi - b \sin [(a + b) \phi / b]$$

$$x = (a - b) \cos \phi + b \cos [(a - b) \phi / b]$$

$$y = (a - b) \sin \phi + b \sin [(a - b) \phi / b]$$

When the point P lies in the plane of (B) but not on the circumference, it generates *epitrochoids* and *hypotrochoids*.

These four kinds of curves attracted the attention of Philippe de la Hire, Gérard Desargues, Leibniz, Newton and others. They admit as special cases many well-known curves such as the cardioid and the deltoid.

34. Bowditch Curves or Lissajous

Curves (fig. 17),  $x = a \sin(m_1u + n_1)$ ,  $y = b \sin(m_2u + n_2)$ , or  $x = a \sin(nt + c)$ ,  $y = b \sin t$ . These curves were first considered by Nathaniel Bowditch (1815) and studied in detail and independently by J. A. Lissajous (1857-58). They find applications in astronomy, physics and other sciences.

35. Sinusoidal Spirals,  $r^n = a^n \cos n\theta$  (where  $n$  is a rational number, positive or negative), first studied by Maclaurin (1718, 1720). For  $n = 1, +1, -1, -2$  and  $+2$ , the curve is, respectively, a line, a circle, a parabola, an equilateral hyperbola and a lemniscate of Bernoulli, a cardioid, . . .

36. Cycloid,  $x = a(\phi - \sin \phi)$ ,  $y = a(1 - \cos \phi)$ , one of the most celebrated of all special curves, is the locus of a point P on the circumference of a circle (C) of radius  $a$  that rolls, without slipping, along a straight line (see fig. 18[A]). The curve was studied by Galileo Galilei (c. 1599), who gave it its name, Roberval (1634), Sir Christopher Wren (1658), Huygens (1673), Johann Bernoulli (1696) and others.

If P lies in the plane of (C) at a distance  $h$  from the centre, ( $h \neq a$ ), the parametric equations of the locus of P are  $x = a\theta -$

FIG. 11.—TRICUSPID

FIG. 9.—CONCHOID

FIG. 13.—DEVIL'S CURVE

FIG. 14.—KAMPYLE OF EUDOXUS

FIG. 10.—LIMAÇON OF PASCAL

$h \sin \theta, y = a - h \cos \theta$ . The curves are *trochoids*, that is, curtate or prolate cycloids, depending on whether  $h < a$  or  $h > a$  (fig. 18[B]).

37. Euler's Spiral or Clothoid or Cornu's Spiral (fig. 19),

$$x = \frac{a}{2i} \int_0^v \frac{\sin v}{v} dv, y = \frac{a}{2i} \int_0^v \frac{\cos v}{v} dv,$$

discovered and studied by Euler (1744).

FIG. 15.—ASTROID OR TETRACUSPID

(1710-13) and Roger Cotes (1722).

(d) The lituus  $r^2\theta = a^2$ , originated with Cotes (1722). It is the locus of the point P moving in such a manner that the area of the circular sector POP' remains constant.

39. Involute of a Circle, the roulette (see section 55) of a point P on a straight line which rolls on a circle of centre O. Its parametric equations are:  $x = a(\cos \phi + \phi \sin \phi)$ ,  $y = a(\sin \phi - \phi \cos \phi)$ . It was conceived by Huygens when he was considering clocks without pendulums which might be of service on seagoing vessels.

FIG. 16.—WATT'S CURVE

40. Cochleoid (snail form) (fig. 21),  $r = a(\sin \theta)/\theta$ . The points of contact of parallel tangents to the cochleoid lie on a strophoid (see section 4).

41. Logarithmic (or Equiangular or Logistic) Spiral, first discussed by Descartes (1638) as the curve cutting radius vectors from a fixed point O under a constant angle  $\phi$ . The polar equation of the curve is  $r = ke^{c\theta}$ , where  $c = \cot \phi$ . The form of the curve depends on  $c$  and is independent of  $k$  (fig. 22).

The pole O is an asymptotic point (Evangelista Torricelli, 1646). The pedal (see section 53) of a logarithmic spiral with respect to its pole is a logarithmic spiral and its evolute (see section 50) is an equal spiral with the same asymptotic point (Jakob Bernoulli, 1691-93).

42. Frequency Curve or Probability Curve or Gaussian Curve or Normal Curve of Errors, the name applied to the bell-shaped curve whose most common Cartesian equation is  $y = (2\pi)^{-1/2} e^{-1/2 x^2}$ . This curve originated, in essence, with Abraham de Moivre (1733); it has been connected more particularly with P. S. Laplace and C. F. Gauss.

The term "frequency curves" is applied to a great variety of curves; see, for example, W. P. Elderton, *Frequency Curves and Correlation*, 4th ed. (1953).

43. Logarithmic (or Logistic) Curve,  $x = a \log(y/m)$  or  $y =$

FIG. 17.—BOWDITCH CURVES

44. Catenary or Chainette (fig. 23), the form which a perfectly flexible chain assumes when suspended by its ends and acted upon by gravity alone. Its equation, obtained by Leibniz and Huygens in 1691, can be written  $y = \frac{1}{2}a(e^{x/a} + e^{-x/a}) = a \cosh(x/a)$ . The tangents at P, P<sub>1</sub> and P<sub>2</sub> on the figure are concurrent. A catenary revolved about its asymptote generates a *catenoid*, the only minimal surface of revolution (Euler, 1744).

$me^{x/a}$ . The curve originated about 1640. The subtangent of the curve is equal to  $a$ , regardless of the value of  $m$ .

45. Tractrix or Tractory or Equitangential Curve, (fig. 24), being equitangential (PN = a), is defined by the equation  $y^2(1 + y^2) = a^2y^2$  or  $x = a(\cos u + \log \tan [u/2])$ ,  $y = a \sin u$ . The curve was studied in detail by Huygens (1692) and by Leibniz, Johann Bernoulli and others. The evolute (see section 50) of the tractrix is a catenary (see section 44). The tractrix revolved about its asymptote generates a *pseudosphere*, a surface of constant negative curvature (Eugenio Beltrami, 1865) of interest in connection with non-Euclidean geometry.

46. Quadratrix of Hippias,  $y = x \cot(\pi x/2a)$  or  $r \sin \theta = (2a/\pi)\theta$ , a curve discovered by Hippias of Elis (c. 430 B.C.) which

FIG. 20.—FAMILY OF CURVES DERIVED FROM  $r^m = a^m \theta$ : (A) SPIRAL OF ARCHIMEDES; (B) FERMAT'S SPIRAL; (C) HYPERBOLA; (D) LITUUS

may have been used by him and by Dinostratus (c. 350 B.C.) for trisecting an angle and for squaring the circle. The curve may be used for dividing an angle into any number of equal parts.

47. Anallagmatic Curve, first discussed by T. Moutard (1827-1901) in 1864, a curve which is invariant under inversion (see section 51), such as the limaçon, cardioid, Cartesian, cassinian, strophoid, trisectrix of Maclaurin, etc.

48. Brachistochrone, the curve along which a body moves from a point A to a point B under the action of an accelerating force in the least time possible. In 1696 Johann Bernoulli proposed the question as a challenge, the accelerating force being gravity. Leibniz, Newton, Jakob Bernoulli and L'Hôpital found that the cycloid has the required property.

49. Caustic. When the light rays emanating from a source S are reflected by a given curve, the envelope of the reflected rays is the *caustic by reflection* or *catacaustic* of the given curve with respect to the source in question. When the rays from S are refracted by a given curve, the envelope of refracted rays is called

FIG. 19.—EULER'S SPIRAL OR CLOTHOID OR CORNU'S SPIRAL

A catenary revolved about its asymptote generates a *catenoid*, the only minimal surface of revolution (Euler, 1744).

45. Tractrix or Tractory or Equitangential Curve, (fig. 24), being equitangential (PN = a), is defined by the equation  $y^2(1 + y^2) = a^2y^2$  or  $x = a(\cos u + \log \tan [u/2])$ ,  $y = a \sin u$ . The curve was studied in detail by Huygens (1692) and by Leibniz, Johann Bernoulli and others. The evolute (see section 50) of the tractrix is a catenary (see section 44). The tractrix revolved about its asymptote generates a *pseudosphere*, a surface of constant negative curvature (Eugenio Beltrami, 1865) of interest in connection with non-Euclidean geometry.

46. Quadratrix of Hippias,  $y = x \cot(\pi x/2a)$  or  $r \sin \theta = (2a/\pi)\theta$ , a curve discovered by Hippias of Elis (c. 430 B.C.) which

FIG. 21.—COCHLEOID

44. Catenary or Chainette (fig. 23), the form which a perfectly flexible chain assumes when suspended by its ends and acted upon by gravity alone. Its equation, obtained by Leibniz and Huygens in 1691, can be written  $y = \frac{1}{2}a(e^{x/a} + e^{-x/a}) = a \cosh(x/a)$ . The tangents at P, P<sub>1</sub> and P<sub>2</sub> on the figure are concurrent. A catenary revolved about its asymptote generates a *catenoid*, the only minimal surface of revolution (Euler, 1744).

45. Tractrix or Tractory or Equitangential Curve, (fig. 24), being equitangential (PN = a), is defined by the equation  $y^2(1 + y^2) = a^2y^2$  or  $x = a(\cos u + \log \tan [u/2])$ ,  $y = a \sin u$ . The curve was studied in detail by Huygens (1692) and by Leibniz, Johann Bernoulli and others. The evolute (see section 50) of the tractrix is a catenary (see section 44). The tractrix revolved about its asymptote generates a *pseudosphere*, a surface of constant negative curvature (Eugenio Beltrami, 1865) of interest in connection with non-Euclidean geometry.

46. Quadratrix of Hippias,  $y = x \cot(\pi x/2a)$  or  $r \sin \theta = (2a/\pi)\theta$ , a curve discovered by Hippias of Elis (c. 430 B.C.) which

the *caustic by refraction* or *diacaustic* of the given curve for the source in question. Catacaustic and diacaustic surfaces may be defined in a similar way.

Caustic curves originated with Huygens and Tschirnhausen about 1678; they were studied by Johann and Jakob Bernoulli, L'Hôpital, Adolphe Quételet, J. L. Lagrange and others.

The catacaustic of a circle is a nephroid (see section 25), a limaçon (see section 14) or a cardioid (see section 15), depending on whether the source of light  $S$  is at an infinite distance (that is, when the incident rays are parallel) (Huygens, 1678), a finite distance (Thomas de St. Laurent, 1826) or on the circumference of the circle (Johann and Jakob Bernoulli, 1692).

FIG. 23.—CATENARY OR CHAINETTE

nal trajectory of the tangents to a given curve. There are an infinite number of such trajectories to a given curve, and they are said to be *parallel curves*; that is, any two cut off equal lengths on common normals. Parallel curves may be very different in appearance; for example, Cayley's sextic (see section 27) and the nephroid (see section 25). Leibniz was the first to consider parallel curves. Fig. 25 shows two parallel curves, 3 and 4, of an astroid, 2, and also the evolute, 1, of this astroid.

51. Inverse Curves. Given a fixed point  $O$  and a constant  $m$ , if two points  $P_1, P_2$ , collinear with  $O$ , are such that  $OP_1 \cdot OP_2 = m$ , they are said to be inverse with respect to one another, or homologous, in the inversion  $(O, m)$  having  $O$  for centre and  $m$  for constant of inversion. The points  $P_1, P_2$  are on the same side of  $O$  if  $m$  is positive and on opposite sides if  $m$  is negative. If one of the points, say  $P_1$ , describes a curve  $C_1$ , the curve  $C_2$  described by  $P_2$  is the inverse  $C_1$  in  $(O, m)$ . The relation between  $C_1$  and  $C_2$  is obviously reciprocal, and the two may coincide (see section 47).

52. Isoptic Curve. The locus of the points of intersection of tangents to a given curve (or a pair of curves) meeting at a constant angle is an isoptic curve of the given curve or curves. When the constant angle is right, the isotopic curve is said to be the *orthoptic curve*. The orthoptic of a parabola is its directrix, the orthoptic of a central conic is a circle concentric with the conic (the *Monge circle*) and the orthoptic of a deltoid (see section 16) is a circle.

FIG. 25.—EVOLUTE

FIG. 22.—LOGARITHMIC SPIRAL

50. Evolute. This is the envelope of the normals of a given curve  $(C)$  or, what amounts to the same thing, the locus of the centres of curvature of  $(C)$ . The concept of the evolute originated with Huygens (1673); however, see Apollonius of Perga, *Conics*, book v.

If the evolute of  $(C)$  is regarded as the basic curve, then  $(C)$  is said to be an *involute*; an involute of a curve is an orthogonal

FIG. 24.—TRACTRIX OR TRACTORY OR EQUITANGENTIAL CURVE

53. Pedal or Pedal Curve. The locus  $C_1$  of the feet of the perpendiculars dropped from a

fixed point  $O$  to the tangents of a given curve  $C$  is said to be the pedal curve of  $C$  for—or with respect to—the point  $O$ . The curve  $C$  is the first negative pedal curve of  $C_1$  for the point  $O$ . The pedal curve  $C_2$  of  $C_1$  for  $O$  is the second positive pedal curve of  $C$  for  $O$ , and so on.

54. Radial or Radial Curve. If through a fixed point rectilinear segments are drawn equal and parallel to the radius of curvature of a variable point of a given curve  $C$ , the locus of the end points of those segments is the radial curve  $R$  of  $C$  (Robert Tucker, 1864). The degree of  $R$  is equal to the degree of the evolute of  $C$  (see section 50). The radial of a conic is a conic; the radial of a cycloid (see section 36) is a circle.

55. Roulette, the path of a fixed point—or the envelope of a fixed line—situated in the plane of a curve, which rolls, without slipping, on a fixed curve or straight line. The term is also applied to the locus of a variable point, such as the centre of curvature of the point of contact of the rolling curve.

The roulette of the vertex of a parabola rolling on an equal parabola is a cissoid of Diocles (see section 3). The pole of a hyperbolic spiral (see section 38) rolling on a straight line traces out a tractrix (see section 45) (A. Demoulin, 1891).

A related curve is the *glissette*, the locus of a point, or the envelope of a line, fixed in the plane of a curve made to slide between given curves. For instance, the locus of a point on a rod of fixed length whose ends slide on two fixed perpendicular lines is an ellipse. The envelope (glissette) of the rod itself is an astroid (see section 26).

56. Tautochrone, a curve down which a particle acted upon by specified forces will descend in the same amount of time from any initial point to the lowest point. When gravity is the force considered, Huygens showed (1673) that the inverted cycloid (see section 36) with axis vertical has the required property. The astroid and the cardioid are tautochrones under certain conditions.

57. Clelies. If  $\phi$  and  $\theta$  denote the longitude and colatitude of a point  $P$  on a sphere of radius  $a$ , and if  $P$  moves so that  $\theta = m\phi$ , where  $m$  is a constant, then the locus described by  $P$  is a clelie. The co-ordinates of  $P$  are

$$x = a \sin m\phi \cos \phi, y = a \sin m\phi \sin \phi, z = a \cos m\phi$$

The locus of  $P$  was studied by Grandi (1728), who used purely geometrical methods. Grandi also applied the term, "clelies" to the curves determined by the equations  $a \sin \theta = b \sin m\phi$ ,  $a \sin \theta = a - b \sin m\phi$ .

58. Loxodrome or Rhumb Line or Spherical Helix, usually defined as the curve cutting the meridian of a sphere at a constant angle. The curve was first conceived by Pedro Nunes (1550). If  $\beta$  is the constant angle, and  $\phi$  and  $\theta$  the longitude and colatitude of a point on the loxodrome, its equation may be written  $x = \sin \phi \cos \theta$ ,  $y = \sin \phi \sin \theta$ ,  $z = \cos \phi$ , where  $\theta = -\tan \beta \log \tan(\phi/2)$ .

Nunes believed that a loxodrome joining two points on a sphere was the shortest distance on the sphere between those points. But 19th century mariners realized that great-circle sailing is preferable for short distances.

59. Helix, the curve cutting the generators of a right circular cylinder under a constant angle. If  $\beta$  is the constant angle, the equations of the curve are  $x = a \cos \theta$ ,  $y = a \sin \theta$ ,  $z = a\theta \cot \beta$ . The helix is mentioned by Geminus (c. 70 B.C.); a passage in Proclus (c. A.D. 460) suggests that it was known to Apollonius (c. 225 B.C.). It was used by Pappus of Alexandria (c. A.D. 300) for producing the quadratrix of Hippias of Elis (see section 46). The orthogonal projection of the helix on a plane parallel to the axis of the cylinder is a *sine curve*.

The curve which cuts the generators of a cone of revolution under a constant angle is a *cylindro-conical helix* or *conical loxodrome*, which was first discussed by Grandi (1701). Its equation may be written

$$x = ke^{\theta} \cos \theta, y = ke^{\theta} \sin \theta, z = ke^{\theta} \cot \beta$$

60. Skew (or Gauche, or Space, or Twisted) Cubic, a space curve which may have three points in common with a plane. The skew cubic may result from the intersection of two quadratic cones, or

of two ruled quadric surfaces having an element in common. It is in this form that the curve was first noticed (A. F. Möbius, 1827). The curve is the locus of the common point of three corresponding planes of three projective axial pencils of planes, or the locus of the common point of two corresponding and coplanar lines of two projective bundles.

A skew cubic is determined by six points, no four of them coplanar. The cone which projects a cubic from a point in space is of third degree, but reduces to second degree if the point is taken on the cubic.

A line in space may be met by four tangents to a skew cubic. A line joining two points, real or conjugate imaginary, of a skew cubic is a *secant* of the curve, while a line having one point in common with the curve is a *semi-secant* or *transversal*.

The skew cubic is also referred to as a *cubical conic section*. The three points of intersection of the curve with the plane at infinity may present the following four cases: (1) the three points are real and distinct; (2) one point is real and the other two are conjugate imaginary; (3) two of the points coincide; (4) all three coincide. The corresponding curves are: (1) *cubical hyperbola*; (2) *cubical ellipse*; (3) *cubical parabolic hyperbola*; (4) *cubical parabola*.

Coolidge, *Treatise on Plane Algebraic Curves* (1931); Harold Hilton, *Plane Algebraic Curves*, 2nd ed. (1932); W. D. MacMillan, *Statics and the Dynamics of a Particle* (1958); Robert C. Yates, *Handbook on Curves and Their Properties* (1952). A considerable amount of information on special curves may be found in books and textbooks on analytic geometry, calculus, differential equations, calculus of variations and mechanics. (R. C. A.; N. A. Cr.)

**CURWEN, JOHN** (1816–1880), English music educationist and founder of the tonic sol-fa system of musical notation. Born on Nov. 14, 1816, at Heckmondwike, Yorkshire, the son of a Congregational minister, he was himself a minister from 1838 until 1864, when he began to devote himself to propagating his new method of musical nomenclature. This was designed to inculcate a sense of the relationship of notes to each other in the diatonic scale and to prepare the music student for a better conception of staff notation. Curwen adapted his system from that of Sarah Ann Glover (1785–1867), whose *Norwich Sol-fa System* (1845) used the syllables of the system of notations of Guido of Arezzo (q.v.), and he also adapted from the system of Aimé Paris (1798–1866) terms for the notation of rhythm. Curwen's method of teaching was founded on the attraction of notes to the tonic and, in modulation, to the principle of a shifting tonic ("the movable *doh*"). In 1853 he founded the Tonic Sol-fa association (later the English Schools Music association) and from then on his method was widely adopted in schools and choral societies. In 1863 he established a printing press for music and three years later became lecturer at Anderson's college, Glasgow. In 1879 the Tonic Sol-fa college (later the Curwen Memorial college) was opened. He died at Manchester on May 26, 1880. His son, John Spencer Curwen (1847–1916), succeeded him as director of the publishing firm and founded in England the competition festival movement for amateur musicians.

See H. W. Shaw, "The Teaching of John Curwen" in *Proceedings of the Royal Musical Association* (1950–51).

**CURZOLA:** see KORCULA.

**CURZON LINE**, a proposed Polish-Soviet armistice line put forth on July 11, 1920, by Lord Curzon, the British foreign minister. It was based on the line established on Dec. 8, 1919, on the territory of the former Russian empire within which Poland was authorized to organize a regular administration. To the south, on the territory of the former Austrian empire, the Curzon line extended along the line A; i.e., one of the two possible partition lines of Galicia between Poland and a Ukrainian state. Originally, the Curzon line was not meant to be a proposed eastern frontier of Poland. It was publicized as such during World War II. See *POLAND: The People's Republic*.

**CURZON OF KEDLESTON, GEORGE NATHANIEL CURZON**, 1st MARQUESS (1859–1925), the last English statesman to belong in spirit to the 18th-century aristocracy, was viceroy of India from 1898 to 1905 and foreign secretary from

1919 to 1924. He was born on Jan. 11, 1859, at Kedleston hall, Derbyshire, eldest of the 11 children of the 4th Baron Scarsdale. His mother died when he was 16. His father was a silent, reserved, evangelical clergyman. Curzon as a boy came under the influence of a formidable governess who taught him hard work by her precept and parsimony by her example, and of a harsh preparatory-school master who crammed him with detailed knowledge. At Eton he was regarded as a prodigy. In 1878 he went to Balliol college, Oxford. In the same year he began to suffer from curvature of the spine, which gave him much pain all his life. It forced him to wear the steel corset from which he acquired that unbending rigidity of figure which seemed, as time went on, to communicate itself to the very processes of his mind. He became president of the Union and, although he failed to gain a first, he was elected in 1883 a fellow of All Souls college. Social life and travel engaged him for the next few years. In 1886 he entered parliament as a Conservative. In 1891 he became undersecretary for India, in 1895 for foreign affairs. Meanwhile he had traveled over America, central Asia, India, China and the middle east and published books based on his experiences. In 1895 he married Mary Leiter, the daughter of a U.S. millionaire. Her charm softened his asperity and her wealth enabled him to live in a style the splendour of which became almost legendary.

In 1898, still under 40, Curzon was appointed viceroy of India, taking office in the new year. His tenure was marked by great achievements but ended in frustration. He created the North-West Frontier province, reorganized Indian finance, established the imperial cadet corps, inaugurated the controversial policy of partitioning Bengal and set up commissions of inquiry on almost every aspect of government and administration. A believer in pomp and circumstance, he reached the apogee of his Indian career when he presided over the great durbar of 1903 held in honour of King Edward VII's coronation. He was reappointed in 1904, but a quarrel with the commander in chief, Lord Kitchener, over the powers of the military member of the viceroy's council resulted in his offering to resign. Kitchener, a past master of intrigue, had powerful allies in London. To Curzon's chagrin his resignation was accepted. He left India in Nov. 1905 bitter and disappointed. In 1906 Lady Curzon died. Curzon, a widower with three young daughters, plunged into inconsolable gloom.

There was little for an opposition peer to do, but in 1907 Curzon was able to seek distraction in the duties of chancellor of Oxford university to which position he had been elected after a contest with Lord Rosebery. He was an active chancellor and initiated useful reforms. In 1911 he was created Earl Curzon of Kedleston and Baron Ravensdale (with reversion to his eldest daughter in default of male heirs). He reappeared in politics as a leading opponent of H. H. Asquith's parliament bill, but he roused the hostility of the Tory die-hards by sensibly voting for the bill when it was clear that rejection could only result in a mass creation of Liberal peers. In May 1915 he became lord privy seal in Asquith's wartime coalition government. He strongly opposed the evacuation of Gallipoli. He as strongly supported conscription, even refusing the Garter till it had been introduced. When Asquith fell at the end of 1916, Curzon joined David Lloyd George's government as a member of the small inner war cabinet. He was kept occupied for the rest of the war, the cabinet meeting not less than 500 times between then and the Armistice. In 1917 he married Grace Hinds Duggan, daughter of a U.S. diplomat and widow of Alfred Duggan of Buenos Aires.

At the beginning of 1919 Curzon took temporary charge of the foreign office in Lord Balfour's absence at the Paris peace conference. In October Balfour resigned and Curzon became foreign secretary, thus fulfilling one of his major ambitions. He was much hampered by bad relations with the prime minister who in matters that interested him did not hesitate to conduct his own foreign policy behind Curzon's back. The worst example of this concerned conflict between Turkey and Greece. Curzon's policy of keeping the Turks out of Europe and the Greeks out of Asia was far more sensible than Lloyd George's encouragement of a Greek invasion of Asia Minor. Curzon, however, could not bring himself to resign on this issue and his threats to do so merely

earned him ridicule. Raymond Poincaré, French prime minister from early 1922, whom Curzon detested, fully exploited this weakness for his own pro-Turkish policy. In the late summer Lloyd George's philhellenic plans crashed in ruin with the utter defeat of the Greek forces and a Turkish threat to invade Europe. Lloyd George successfully threatened war with the Turks if this occurred, but on Curzon fell the task of negotiating with Poincaré arrangements for an armistice in Turkey. The coalition government was badly shaken by the crisis and the leaders, Curzon included, resolved to appeal to the electorate. A few days later, however, Lloyd George engaged in another secret maneuver behind Curzon's back and the latter resolved at last to resign. He joined Andrew Bonar Law, who became prime minister in Oct. 1922, and the foreign secretary could feel that he was at last master in his own house. He dominated the conference of Lausanne held to settle the Turkish affair during the winter of 1922-23 and, although he had to carry out his threat to leave by Feb. 4 if a treaty was not signed, he had already secured the main British interests.

In May 1923 ill-health forced Bonar Law to resign. Curzon expected to succeed him as prime minister but to his bitter disappointment he was passed over in favour of Stanley Baldwin—ostensibly on the ground that a peer could not be prime minister; in reality because Curzon's pomposity and apparent arrogance were considered handicaps in a democratic age. He showed great magnanimity in serving loyally under Baldwin till the latter's electoral defeat in the autumn of 1923. When Baldwin formed his second government in 1924 Curzon was not offered the foreign office, but he accepted the position of lord privy seal. On March 20, 1925, he died in London after a short illness. Curzon had been made a marquess in 1921. That title and the earldom now became extinct. The barony of Ravensdale descended to his eldest daughter.

If Curzon had had the gifts of character often possessed by persons of much lesser ability he might have reached the top. As it was he lacked determination; he was too inclined to lose himself in detail; he failed to realize that a memorandum, however brilliant, is not a substitute for action; and he always inspired a certain mistrust. His career, in Sir Harold Nicolson's words, was one of "successes rather than success."

See Earl of Ronaldshay, *The Life of Lord Curzon*, 3 vol. (1928); Harold Nicolson, *Curzon: the Last Phase, 1919-1925* (1934).

(R. N. W. B.)

**CUSCATLÁN**, most centrally located department of El Salvador. Area 283 sq.mi., pop. (1958 est.) 113,489, of which 75% was rural. The land is mostly rough, but rice, sugar, henequen and tobacco are grown. Sesame, fruits, vegetables and livestock are also produced. The departmental capital, Cojutepeque (pop. 18,247), was founded in 1571 and lies at an altitude of 2,625 ft., 21 mi. from San Salvador on the Inter-American highway. On Aug. 29 Cojutepeque celebrates the feast of St. John, which draws thousands of people to join in the festivities and to trade their wares.

(C. F. J.)

**CUSCO**, Peru: see Cuzco.

**CUSH**, the eldest son of Ham in the Bible, from whom seems to have been derived the name of the Land of Cush, commonly rendered Ethiopia by the Septuagint and the Vulgate. The exact territory thus designated is uncertain, some maintaining that it lay in Africa, in which case it would be the country to the south of Aswan, others that it is in Arabia, while a third view associates the name with the Kassites (q.v.), who for several centuries dominated Babylonia. The various references suggest that the term may have been applied to districts in all three regions.

**CUSHING, CALEB** (1800-1879), U.S. lawyer, politician and diplomat, was born on Jan. 17, 1800, in Salisbury, Mass., of a distinguished colonial family. He graduated from Harvard at the age of 17, studied law and was admitted to the Massachusetts bar in 1821. Although retained in many important cases, he spent much of his mature career in public service. After several terms in the state legislature he was elected to congress as a Whig, holding his seat from 1835 to 1843. When Tyler succeeded to the presidency after Harrison's death in 1841, Cushing deserted the Whigs and allied himself with the Democrats. He was rewarded

in 1843 with a nomination as secretary of the treasury but confirmation was refused by a hostile senate. He was then approved as U.S. commissioner to China where he negotiated the treaty of Wanghia (1844), establishing the principle of extraterritoriality. During the Mexican War he was a colonel and later a brigadier general of volunteers, marching with troops from Veracruz to Mexico City, but saw no action in the field. In 1847 and again in 1848 the Democrats nominated him for governor of Massachusetts but each time he failed of election. In 1852 he became an associate justice of the Massachusetts supreme judicial court.

Regarded as a "northern man of southern principles," he was named in 1853 by the Democratic president, Franklin Pierce, as U.S. attorney general, and became one of the most influential cabinet members. He was a natural choice as chairman of the Democratic national convention at Charleston in 1860 and continued to preside when seceders reconvened at Baltimore and nominated Breckinridge. With the outbreak of the American Civil War, however, he gave loyal support to Lincoln and the Union. He enjoyed the confidence of President Grant, who named him as counsel for the United States at the Geneva conference (1871-72) for the settlement of the so-called "Alabama" claims. In 1873 Grant nominated him as chief justice of the United States, but exposure by political foes of his earlier friendly relations with Jefferson Davis led to his rejection. From 1874 to 1877 he was U.S. minister to Spain. He died on Jan. 2, 1879, at his home in Newburyport, Mass.

Cushing published several books, the most important being *The Treaty of Washington* (1873). Scholarly in his tastes, he was also aggressive, politically ambitious and more respected than loved. He was a highly controversial figure who changed parties twice and played a conspicuous part in American affairs for half a century.

See C. M. Fuess, *The Life of Caleb Cushing* (1923). (C. M. F.)

**CUSHING, HARVEY** (1869-1939), U.S. surgeon noted for his work in neurological surgery, fourth in direct line of a family of physicians, was born at Cleveland, O., on April 8, 1869. He graduated from Yale university in 1891 and from the Harvard medical school in 1895. After four years at Johns Hopkins hospital he studied abroad under Kocher at Berne and Sherrington at Liverpool. On his return to Baltimore he held various positions in the department of surgery at Johns Hopkins university, becoming associate professor in charge of cases of surgery of the central nervous system. He wrote numerous monographs on the surgery of the brain and developed the method of operating with local anesthesia. His work on the pituitary body (1912) gave him an international reputation. He also made important contributions to the study of blood pressure in surgery and to the classification of brain tumours. From 1912 to 1932 Cushing was professor of surgery in the Harvard medical school and surgeon-in-chief at the Peter Bent Brigham hospital in Boston. During World War I he was director of a U.S. base hospital in France, and in 1918 was made senior consultant in neurological surgery to the American Expeditionary Forces. His *Life of Sir William Osler* (1925) received the Pulitzer prize for biography. From 1933 to 1937 he was Sterling professor of neurology at Yale university. Cushing died at New Haven, Conn., on Oct. 7, 1939.

**CUSHING, WILLIAM BARKER** (1842-1874), U.S. naval officer, noted for his exploits during the American Civil War, was born in Delafield, Wis., on Nov. 4, 1842. His father's early death forced him and his two brothers, who later displayed great gallantry in the army, to assist their mother. He was for a time a congressional page, but in 1857 received an appointment to the U.S. naval academy, from which he was obliged to resign in 1861 as the result of a prank played on one of his professors. The outbreak of the Civil War gave him, however, an opportunity to redeem himself, of which the self-styled "ex-midshipman, ex-master's mate, hare-brained scapegrace" took the fullest advantage. Coolness, daring, exceptional resourcefulness and good fortune, which caused the more superstitious of the sailors to believe him invulnerable, made him the hero of a series of spectacular feats. Foremost among them was the destruction of the Confederate ironclad "Albatross" in the Roanoke river on Oct. 27,

1864. This vessel, which had done much damage to the Federal naval forces, was at anchor when Lieutenant Cushing in a steam launch succeeded in eluding the Confederate lookout and in exploding against her a spar torpedo with such success that she sank. Cushing's own launch was destroyed and the crew compelled to take to the water, only he and one other man escaping capture or death. For that achievement he was thanked by congress and made lieutenant-commander. He was promoted to commander at the early age of 30. Cushing died at Washington, D.C., on Dec. 17, 1874.

See a sketch by C. F. Stewart, which contains autobiographical material, in U.S. Naval Institute, *Proceedings*, vol. xxxviii, pp. 425-491, 913-991 (1912); T. W. Haight, *Three Wisconsin Cushings* (1910).

**CUSHITE LANGUAGES**, the name given to a group of languages spoken from the Red sea littoral to the area south of the Horn of east central Africa. See **AFRICAN LANGUAGES: The Hamito-Semitic (Afro-Asiatic) Languages**.

**CUSHITIC PEOPLES**, the Hamitic and partly semitized inhabitants of the Horn of Africa. Physically like the Hamites (q.v.), the Cushites are generally of above-average stature, their facial features showing Caucasoid and Semitic rather than Negroid characteristics although the skin colour is often very dark. Despite a presumed common origin, their economy, culture and social organization vary widely, partly in relation to local climatic and ecological conditions and partly as a result of mixing with Semitic and Negroid peoples. They include peoples of such different culture as the egalitarian Somali nomads, the Tigre- and Tigrinya-speaking peoples, and the Amhara of the Eritrean and Ethiopian highlands with their highly developed agricultural system and complex hierarchical political structure. The Galla, partly pastoralists and partly cultivators, occupy an intermediate position and, with their age-set political organization, differ sharply from their closely related neighbours, the Somali. The Sidama, an agricultural tribe in southwest Ethiopia, grow a wide range of crops and are traditionally organized in states ruled by divine kings.

Some "Cushitic" peoples speak Semitic languages. These are the Tigre-speaking peoples (the Beni 'Amer and Bait Asgade, Marya and Mensa); the Tigrinya speakers (the tribes of Akala Guzay, Hamasen, and Seræ in Eritrea, and others in Ethiopia); and the Amharic-speaking Amhara and the Gurage. There are equally wide variations in material culture. In religion, however, a common strain is discernible in the cult of the Cushitic sky god (*sar* or *waq*), although submerged or transfigured among the strongly Christian and Muslim communities. See also **AFRICA: Ethnography (Anthropology)**, *Northeast Africa*; also entries under various tribal names; for the Cushitic languages see **AFRICAN LANGUAGES: The Hamito-Semitic (Afro-Asiatic) Languages**.

Conti-Rossini, *Etiopia e genti di Etiopia* (1937); S. F. Nadel, *Races and Tribes of Eritrea* (1943); C. G. Seligman, *Races of Africa*, 3rd ed. (1956); G. Sergi, *Africa, Antropologia della stirpe Camitica* (1897); J. S. Trimingham, *Islam in Ethiopia* (1952). (I. M. L.)

**CUSHMAN, CHARLOTTE SAUNDERS** (1816-1876), in her prime the foremost actress in the United States, was born in Boston, Mass., on July 23, 1816. At the age of 19 she made her operatic debut as Countess Almaviva in *The Marriage of Figaro*, and is said to have possessed a fine contralto voice. Her singing voice failed, however, and she switched to the dramatic stage, appearing successfully as Lady Macbeth in New Orleans, La. In 1837 she first played Meg Merrilies in *Guy Rimering*, her most popular role. Miss Cushman accompanied W. C. Macready on an extensive American tour, developing into a polished actress. In 1845 and again in 1854-55 she fulfilled successful engagements in London, where her Romeo, played opposite her sister Susan's Juliet, was applauded. Her best parts were Lady Macbeth, Hamlet, Cardinal Wolsey, Queen Katherine and the ever popular Meg Merrilies. Retiring to Italy in 1852, she spent the subsequent 18 years in farewell tours. She returned to the U.S. in 1870 and died in Boston on Feb. 17, 1876. Her acting was in the grand manner of David Garrick, and her commanding figure and voice were ad-

mirably suited to the rhetorical style. Although she was sometimes criticized for lacking femininity on the stage, she was generally regarded as being unsurpassed in the evocation of powerful emotions and sympathy.

See Emma Stebbins, *Charlotte Cushman* (1878); William Winter, *Other Days* (1908). (S. W. H.)

CUSPS: (ABOVE) EARLY ENGLISH; (BELOW) GOTHIC

**CUSP**, technically, the intersection of two curves; hence, in architecture, the intersections of lobed or scalloped forms, particularly in arches (cusped arches) and tracery. Thus the three lobes of a trefoil (clover-leaf form) are separated by three cusps. Cusped forms appear commonly in early Islamic work, as in the mosque of Ibn Tulun at Cairo (c. 875), and were especially common in the Moorish work of north Africa and Spain. The cusp is found occasionally in the Romanesque work of France, as in the chapel of St. Michel de l'Aiguille at Le Puy en Velay (probably late 11th century), due perhaps to influence from Spain, but it did not become popular until the Gothic period, during which it was used universally and frequently enriched with representations of leaves, flowers or even human heads at the tip.

**CUSTARD APPLE**, a name loosely applied to the fruit of various species of the genus *Annona* (family Annonaceae), shrubs or small trees of the new world tropics and Florida. The fruit of *A. reticulata*, the common custard apple, or bullock's heart of the West Indies, is dark brown in colour, and marked with depressions, which give it a quilted appearance; its pulp is reddish yellow, sweetish and very soft (hence the common name); the kernels of the seeds are said to be poisonous. The soursop is the fruit of *A. muricata*, native of the West Indies. The sweetsop (q.v.) is produced by *A. squamosa*, a native of tropical America and widely cultivated in the tropics. *A. cherimola* yields the Peruvian cherimoya, which is a much esteemed fruit of superior flavour. *A. glabra*, alligator apple or corkwood, a native of South America and the West Indies, is valued for its wood, which serves the same purposes as cork; the fruit, commonly known as the alligator apple or pond apple, is not eaten fresh but is sometimes used for making jellies. See **ANNONACEAE**; **CHERIMOYA**.

**CUSTER, GEORGE ARMSTRONG** (1839-1876), U.S. cavalry officer who was killed, along with all his men, in a battle with Indians in 1876. He was born in New Rumley, O., attended the U.S. military academy at West Point and graduated at the foot of his class in 1861. With the American Civil War then under way Custer was assigned to the cavalry, with which he took part in the first battle of Bull Run. From the very outset of the war Custer revealed daring and brilliance as a cavalry officer, and promotions were numerous and rapid. He was attached to the staff of Gen. George B. McClellan and later became brigadier general of a Michigan volunteer cavalry brigade that distinguished itself in the battle of Gettysburg. In 1864, when the cavalry corps of the Army of the Potomac was reorganized under Gen. Philip H. Sheridan, Custer was assigned to Sheridan, and throughout the remainder of the fighting the long-haired, dashing Custer skyrocketed in rank and in national renown. During the closing two weeks of the war it was Custer's relentless spearhead pressure on Gen. R. E. Lee that helped to hasten the surrender at Appomattox. Custer emerged from the war as one of the most brilliant cavalry leaders in the Union army.

In 1866 Custer was made lieutenant colonel of the 7th U.S. cavalry in the regular army and ordered to Kansas to take part under Gen. W. S. Hancock in an expedition against the Cheyenne Indians. A crushing defeat was inflicted upon the Indians at the Washita river in Nov. 1868. After five leisurely years during which he wrote *My Life on the Plains* (1874), Custer and the 7th regiment were ordered against the Sioux, led by Sitting Bull and Crazy Horse, in Dakota and Montana. Custer, in command of one

of two columns of a projected two-pronged attack, under the command of Gen. A. H. Terry, arrived near the huge Indian encampment on the Little Bighorn river on the night of June 24, 1876. The other column, commanded by Terry, was due to join the Custer forces two days later. But Custer disobeyed orders. Instead of effecting the rendezvous with Terry, Custer, on the morning of June 25, divided his command into three units and attacked the Indians. The central unit, commanded by Custer and consisting of 267 officers and men (including 5 civilians and 3 Indian scouts), rode into the midst of the enemy and was slaughtered. A single horse, "Comanche," survived and for years thereafter appeared at 7th cavalry parades, saddled but riderless.

**CUSTOM**, in general, a practice that has become habitual. Thus a tradesman calls those who are accustomed to deal with him his customers and the resulting trade their custom. In the plural, the word is used for a tax or toll levied upon goods at the time of importation (see **TARIFF**).

In English law, a custom is an ancient rule of law for a particular locality, differing from the common law of the country. Traditionally, much of the common law was based on what had become customary in the country at large, and in this sense custom is indeed the mother of all institutions. But judges and lawyers probably contributed to it more of their own ideas of what was just and proper than is generally admitted, and in any case the term custom soon became confined to its modern meaning of local custom. As such, it tended to limit the growth of the universality and omnipotence of the central government. This state of affairs may be contrasted with the position in medieval Europe, where the legal systems were at first largely systems of local customary laws. At least in Spain, Germany and northern France, compilations had by the end of the 13th century reduced such customary law to writing, with many minor reforms; and this provided much support for a people's local law against the rulers' encouragement of the Roman legal tradition.

At common law the principal requirements for a valid custom are: (1) that it has been enjoyed as of right, peaceably, continuously and uninterruptedly from time immemorial; (2) that it is reasonable, certain and obligatory (i.e., not such that persons may choose whether or not to be bound by it); (3) that it is confined to some defined locality. In some respects these requirements seem more stringent than they are. Thus, enjoyment from time immemorial (i.e., from 1189) will be presumed from evidence of continuous enjoyment as far back as living testimony can go. A wide variety of customary rights may exist; e.g., for the inhabitants of a parish or town to use certain land for games or recreation, or to pass over a path or road over certain land, or to repair roads, or to draw water. There can, however, be no custom to take soil or its produce, for this would be unreasonable, as tending to the destruction or exhaustion of the subject matter itself.

Custom must be distinguished from usage. A usage need not have existed from time immemorial, and it applies to a particular trade, business, profession or occupation and not to a locality. A usage must be certain, generally known, reasonable and not inconsistent with any positive rule of law. The usual effect of a usage is to annex certain terms and provisions to any contracts made between persons affected by it, or to attach particular meanings to terms used in those contracts. Usages exist in great variety and often relate to matters such as the payment of commissions, the delivery of goods, the operation of ports, the terms of employment and the payment of legal costs.

In the United States, custom played a small part. The developed English law was readily available, and except in Louisiana it was received throughout the country. The procedure was to modify the common law to suit American conditions rather than to accept customs as local exceptions to the common law. As settlers

advanced further west, the novel conditions of life in mining communities and in desert country, and many fiercely competing interests, gave rise to a rapid growth of informal rules, many of which the courts and the legislatures soon turned into formal law. Usages, however, have a wide scope.

See **COMMON LAW**; see also references under "Custom" in the Index.

**CUSTOMS**: see **TARIFF**.

**CUTCH** (KUTCH, KACHH), a former chief commissioner's state of India (area 17,060 sq.mi., including 8,424 sq.mi. of the Rann of Cutch), became a district of Bombay state in 1956 and of Gujarat in 1960. It is a peninsula lying between the Sir river, Sir creek and the Great Rann of Cutch on the northwest and the Gulf of Cutch on the east. A range of rocky hills crosses it from east to west and the country is bare and wild with a few cultivated fields near the villages. Summer temperatures are high, often 100°–105° F.; there are dust storms in April and May and the monsoon is unreliable. The many hill streams are almost dry except during the rainy seasons when they are full and rapid. Wells and springs near the Rann are saline, and elsewhere water is scarce and brackish. Eleven dams begun during the 1950s were designed to increase the irrigated land by 67,800 ac.

Some millet, barley, wheat, pulses and cotton are grown, and there are deposits of gypsum and beds of limestone and marble. Bhuj, the district capital (pop. [1961] 40,180) is inland, 190 mi. W. of Ahmedabad. The natural harbour of Kandla on the Gulf of Cutch has been developed as a major port to serve the northwest part of the republic of India. Bhuj is connected with the main Western railway (Delhi-Bombay) via Kandla and Palanpur.

The Gulf of Cutch, to the south, leads to the Little Rann of Cutch. An ocean port established at Okha at the western end of its southern shore was not a success and in 1948 the Indian government began the development of Kandla.

The Ranns (or Runns) of Cutch are two large areas of salt marsh bordering the state: the Great Rann to the north and the Little Rann to the southeast. They are dry in the hot season but flooded by brackish water during the southwest monsoon. There is some salt production. (See **THAR DESERT**.)

**The People**.—Tyranny, and famine and pestilence resulting from the uncertain rains, have contributed in the past to thin the population of Cutch. The inhabitants numbered 696,440 in 1961. One-quarter were Muslims and the remainder Hindus of various castes. The Jadeja Rajputs are the aristocracy of the country, claiming connection with the former rulers and descent from a prince who reigned in Sind about A.D. 900. These Rajputs were much influenced by their contacts with Islam. The artisans are celebrated for their ingenuity. The palace at Mandvi and a tomb of one of their princes at Bhuj are examples of their architectural skill. There are special manufactures of silverwork, silk and cotton and embroidery. The maritime population supplies good sailors. The language is Kachhi (or Kacchi), an Indo-Aryan tongue transitional between Sindhi (Sindi) and Gujarati (q.v.).

**History**.—Little is known of the early history of Cutch. In the 13th century Samma Rajputs fleeing from Sind found asylum with the Chavada Rajputs of Cutch and about 1320 they overthrew their hosts. From 1540 to 1760 there was a United Rajput rule. Thereafter Muslim invasions from Sind led to a brief period of Muslim rule, and in 1813 a Rajput returned to power. In 1815 a British army invaded the Ranns and concluded a treaty with the ruler Maharao Bharmulji, stipulating that Anjar be ceded to them in perpetuity. Following this ruler's deposition in 1819 his infant son Rao Desalji II was enthroned. During his reign much was done to suppress infanticide, suttee (q.v.) and the slave trade in the state. Under British rule Cutch was first subject to the governor of Bombay. Later it was placed under an agency, and following Indian independence it was administered for the central government by a chief commissioner.

**CUTHAH**, an ancient city of Mesopotamia, mentioned in the Old Testament (II Kings xvii. 24), correctly identified by Sir Henry Rawlinson with the mound Tall Ibrahim, 20 mi. N. of the site of Kish and 35 mi. S.E. of the site of Sippar in central Iraq. A canal named the Irinna flowed past it. The mound is 60 ft.

high and 2 mi. in circumference. Cuthah was devoted to the cult of Nergal, the god of the lower world, who was worshiped in every Sumerian city. Cuthah, because of its sanctity, seems to have been kept in repair by all Sumerian and Semitic rulers down to the last few centuries before the Christian era.

See *Cambridge Ancient History*, vol. i, 2nd ed. (1924).

(M. E. L. M.)

**CUTHBERT, SAINT** (d. 687), prior and then bishop of Lindisfarne (see HOLY ISLAND), was a firm supporter of the synod of Whitby's decision about the date of Easter although himself trained in the Celtic church tradition. Probably a Northumbrian by birth, he was a shepherd before entering the monastery of Melrose in 651, where he became prior ten years later. In 664 he was transferred to Lindisfarne as prior after the departure of Colman (q.v.), but in 676 retired to Farne Island to devote himself to prayer. In 684 he was persuaded by Egfrith, king of Northumbria, to become bishop of Hexham, a see which he exchanged in 685 for that of Lindisfarne. In 687 he again retired to Farne Island, where he died on March 20, which is kept as his feast day. After many moves his remains finally were deposited in Durham (999). Cuthbert left on his contemporaries a deep impression of spirituality and love of his neighbours, fully vouched for by the sources for his biography, which are exceptionally good.

See B. Colgrave (ed.), *Two Lives of St. Cuthbert*, a life by an anonymous monk of Lindisfarne and Bede's prose life (1940); C. F. Battiscombe (ed.), *The Relics of St. Cuthbert* (1956).

**CUTLASS FISH** (HAIRTAIL), a marine fish of the family Trichiuridae, whose characteristics are a long bandlike body terminating in a threadlike tail, and strong prominent teeth in both jaws. One of the most widely distributed forms is the five-foot Atlantic cutlass fish (*Trichiurus lepturus*). See also FISH.

**CUTLER, MANASSEH** (1742–1823), U.S. Congregationalist clergyman and a leading figure in the second Ohio company (q.v.), was born at Killingly, Conn., on May 13, 1742. He graduated from Yale in 1765, worked as a schoolteacher, whaling merchant and lawyer, and in 1771 entered the Congregationalist ministry, his major service being given to the congregation at Ipswich hamlet (now Hamilton, Mass.). He was cited for heroism as a Revolutionary War chaplain. In later years he supplemented his ministry by practising medicine and conducting a private boarding school. A versatile man, Cutler took a prominent part in organizing the Ohio company in 1786, and as its agent negotiated in 1787 a contract with the Continental Congress for the purchase of 1,500,000 ac. of public land around Marietta, O. It is frequently claimed that during these negotiations Cutler also acted as a leading author of the Northwest ordinance of 1787, but the available evidence does not support the claim. Cutler was a Federalist member of congress (1801–05), conducted investigations in astronomy, meteorology and botany, and won election to various learned societies. He died in Ipswich hamlet, July 28, 1823.

See W. P. and Julia P. Cutler, *The Life, Journals, and Correspondence of Manasseh Cutler* (1888). Edward Channing's *History of the United States*, vol. iii, pp. 541–543 (1912), says all that can be fairly said about Cutler's part in the Northwest ordinance. (Z. E. M. H.)

**CUTLERY** is the name given to various types of knives and cutting instruments used for domestic and manufacturing purposes. It includes razors, scissors, butchers' and cooks' knives, carving forks and steels used for sharpening knives. Table forks and spoons form another trade, although many manufacturers produce the whole range (see FLATWARE).

**Early History and Development.**—In prehistoric times, cutting tools and weapons used for hunting and defense were made from stones and flint. When man acquired a knowledge of the use of metals, cutting tools were made of bronze and iron. The Romans taught the early Britons how to work iron, and the Norman invaders are said to have brought with them many smiths and skilled metalworkers. Some of the early knives and weapons became famous for their perfection; for example, the skilfully produced Toledo and Damascus blades.

The bulk of the world's cutlery is produced in certain cities in the United Kingdom, France, Germany, Sweden, Italy and the United States. In the first three cases, this localization was largely

due to the natural resources of Sheffield, Thiers and Solingen respectively. In each of these towns swiftly flowing streams were available for turning water wheels, the first major power units in the cutlery industry.

The name of Sheffield was associated with cutlery by the poet Chaucer (1328–1400) when, in describing a miller, he wrote: "A Scheffeld thwitel baar he in his hose." A "thwitel" was the single-bladed "all-purpose" knife that every man carried.

In the United States there are important centres of cutlery manufacture, especially in the New England states. An interesting feature in the development of American cutlery production was the rapid adoption of machine processes and the passing of certain branches of the industry into the hands of some of the leading U.S. engineering firms. A similar movement in the direction of extended employment of machine methods also took place at Sheffield, Solingen and Thiers, notably at Sheffield between 1918 and 1923, following the discovery of stainless steel (q.v.) in 1912 by Harry Brearley. Previously, steel for cutlery, although of a high quality suitable for making into cutting implements, was easy to forge when red hot, either by means of mechanical hammers or by hand. (There were several thousand hand forgers of knife blades in each centre of production. The clanging of their hammers on the anvils set in stone blocks close to coke hearths blown by hand bellows was a feature of the industry.) Stainless steels, however, have to be heated to much higher temperatures than ordinary carbon steels before they become sufficiently malleable to be forged and this necessitated the redesigning of heating equipment. Coke hearths were superseded by gas and electric furnaces, by molten "salt" baths and later by electrical induction heating coils. Furthermore, stainless steels may be forged satisfactorily only within a small range of temperature. When stainless steels begin to cool, partial hardening in air takes place and forging must be stopped. Therefore, high-speed mechanical forging hammers were designed and developed to enable forging to be completed rapidly before the stainless steel could have time to cool and harden. Concurrently, better-quality steels were developed for the forging dies, which had to withstand harsher treatment. Between 1920 and 1930 the techniques of forging were revolutionized and the substitution of stainless steels for carbon steels spread rapidly from Sheffield to all the other manufacturing centres.

**Types of Cutlery.**—There are many types of cutlery, each having distinctive uses. They vary from small wafer blades used in safety razors to such larger cutting instruments as carving knives or tailors' shears, and they may be divided into the following classes: table knives, butcher and kitchen knives, pocketknives, scissors, razors, safety razors and miscellaneous cutting tools essential in other industries and trades such as rubber-tapping knives, machetes, knives for painters and leatherworkers, shears for weavers, etc.

In all these types the blade is the part that determines the usefulness of the tool or instrument. The sharpness of the blade depends on the quality of the steel employed in its production, and on the skill with which it is manipulated during manufacture. The quality of blade material and workmanship determines the final cost, although the cost also varies according to the material used for the handle and the amount of ornamentation it bears.

In the early days of the manufacture of high-grade cutlery both cast steel and shear steel were used, and the cutlery made from these steels is specially notable for the quality and durability of its cutting edge. Cutlery steel is iron with 0.35%–1% of carbon dissolved in it. Up to the 18th century partial solution of carbon in iron was achieved by repeatedly spreading charcoal on red-hot bars and hammering the carbon in, causing the iron to absorb it gradually and turn into steel. A more refined technique was to arrange bars of steel in layers with charcoal between and surrounding them and then to heat the whole stack for many hours. It was by this method that shear steel, famous for its cutting properties, was made.

In 1740 Benjamin Huntsman opened a steel works in Sheffield in which crucible-cast steel was made by dissolving carbon in molten iron. The local cutlers declared this steel to be too hard and refused to use it until they discovered that the cutlery coming from

continental Europe, made from Huntsman's crucible steel, was far superior to their own products.

In the 19th century open-hearth steel began to be used for table knives and scissors, but stainless steel came to be almost universally demanded. The word stainless is not a strictly accurate description of the properties of this steel, though it does resist corrosion from common household acids and alkalis to a remarkable degree. The resistance by the blade to corrosion depends on the chromium content of the steel (usually about 14%), on correct hardening and tempering and on the proper manipulation of the grinding and finishing processes.

**Production of Table Cutlery.**—Blades for table cutlery are produced in five successive production steps: (1) forging the steel into the desired shape, (2) hardening and tempering it correctly, (3) grinding the steel to a cutting edge and removing all traces of forging and heat treatment, (4) polishing the steel and (5) making, fitting and polishing the handle. The fifth step is also known as cutting.

**Forging.**—The better-quality knife blades are forged by mechanical hammers from bars of steel. By one method the ends of several bars are heated together in a gas-fired or electric furnace. One at a time the bars are removed and the red-hot end placed between forging dies that rapidly hammer out the rough blade shape desired. The first part of the forging operation is completed by "parting off" each blade on a knife edge incorporated with the forging dies, leaving a small portion of steel to be reheated and stamped into the bolster, or shoulder, shape selected. Usually each bar of steel remains red-hot long enough for two or three blades to be roughly forged and parted off. The cooling bar is returned to the furnace and one of the other red-hot bars is drawn out to be forged. The amount of steel utilized is so calculated beforehand as to leave a further small piece beyond the bolster that is forged out into the "tang," to which the handle will be attached later. The final blade shape is obtained by trimming the forgings with a pair of cutting tools in a machine press. Some knives are made as complete forgings of blade and handle by one stroke of a large drop-forging hammer; others, cut out from sheet steel so that a short flat tang without a forged bolster is left, are called "whittle tangs."

In Sheffield the mechanical forging of blades is called "goffing," said to be derived from the household goffering iron of the 16th century used to produce pleats in ruffles. The term was applied derisively to blades produced by the old tilt hammers because of the unevenness of the blades' surfaces compared with those of blades hand-forged by craftsmen. With the improvement in forging technique these defects were overcome but the term "goffing" continues in Sheffield to denote the mechanical forging of table-knife blades.

**Hardening and Tempering.**—After the blades are forged or cut out they are hardened by heating in either a gas or electric furnace, a molten "salt" bath or a magnetic induction coil to a temperature of 1,400° F. for ordinary steel or 1,740° F. for stainless steel and then quenched, that is, immersed, in a cooling liquid. The liquid may be oil, brine or water. Alternatively, the blades may be quenched between metal plates cooled by an internally circulating liquid.

The blades are now hard but too brittle to be ground to a cutting edge. They are therefore tempered by reheating to 390° F. and again quenching, which reduces the hardness and gives the blades the correct degree of flexibility and toughness.

There are several types of instruments for obtaining the exact measure of hardness of the material and for reading and controlling temperatures in furnaces. Toward the middle of the 20th century automatic machines were introduced for these heat-treatment processes.

**Grinding and Polishing.**—Machine grinding largely superseded hand grinding although many craftsman grinders were employed in the early 1960s at all the manufacturing centres for the production of small quantities of special shapes. Grinding consists of applying the blades to the rapidly revolving periphery of an abrasive wheel. The grains of the abrasive act like tiny cutting tools, removing the steel until the desired tapers from the back to

cutting edge and from bolster to point are attained. The blade is kept cool with water or a "cutting fluid" to maintain its temper.

Accurate jigs for holding the blades and machine motions for achieving the correct forms have been developed but the highly skilled craftsmen, grinding by hand, still maintain their traditional customs. In Sheffield they sit astride a saddle-shaped wooden seat called a "horsing" mounted over the grindstone, which revolves away from them; in Solingen the wheels revolve toward them; in Thiers they lie flat upon boards placed over the wheels, which revolve toward them. Large blades are held in the hands and extra pressure is applied through a stick hinged to the wheel mountings. Care must be taken not to apply sufficient pressure to cause overheating of the steel, which would soften or "burn." Small blades are mounted in a variety of holders. The grinders must be ambidextrous for the blade has to be ground on both sides.

Sandstone grinding wheels were superseded by wheels made of synthetic materials in a wide range of grits and bonds. The 20th-century grinding wheel has eliminated the dangers of contracting respiratory diseases, such as silicosis, caused by inhaling sandstone dust.

The surface of a blade after grinding, either by machine or by hand, is given a finer finish by successive finer grinding operations known as glazing and buffing, followed if desired by mirror polishing or "satin" finishing. The bolsters are also ground, glazed and polished to fit the desired handle. The maker's name is applied by acid or electric-arc etching.

**Cutting.**—Natural materials for handles include animal horns and tusks, various woods, mother-of-pearl and bone; manufactured handles range from gold, silver and porcelain to stainless steel, silver plate, nickel alloys, compressed wood and plastics. Some of these materials are processed mechanically, others by the cutler. Natural stag horn handles have to be matched to each blade individually since no two are alike. Cellulose adhesives, cements or resin mixtures are used to fix the tangs securely in the handles but hollow metal handles are secured by hard soldering.

The final hardness of the blade is ascertained by a machine that applies a pointed diamond or a small steel ball to the surface at a known pressure and measures the resulting indentation. The smaller the size of the indentation the greater the hardness.

By varying the processes, a wide range of knives can be produced. Among the better-known varieties are carving knives, steak knives and bread knives with plain, scalloped or serrated edges, barbecue knives, and specialized knives used by butchers, cooks, farriers, artists and farmers. Knives of special shapes and sizes are made for many industrial processes.

Since the introduction of stainless cutlery steel and the general development of scientific knowledge and manufacturing techniques, cutlery making has been transformed from a handicraft to a highly specialized industry, with its own design, research and laboratory services.

**Shapes of Knife Blades.**—The earliest table-knife blades were sharply pointed, probably for carrying food to the mouth before the use of forks became general. In the 18th century the points were rounded to render them less dangerous. A curved or scimitar-shaped blade was preferred in the 18th century and a straight one in the 19th century. The knife having a short 3½-in. blade and a long 5-in. handle was introduced about 1929 in the United States and the United Kingdom. Twentieth-century designers in all the cutlery-producing countries introduced many variations of blade shapes that harmonized with the lines of the handles.

**Pocketknives.**—The earliest known pocketknife had a blade about three inches long hinged to a slotted handle into which it folded. It is uncertain at what date a spring was added but rare examples of old spring knives now in the Sheffield Cutlery company collection were made in the 17th century.

The forging of pocketknife blades is similar in its essentials to that of table-knife blades and similar materials are used for the hafts (handles) or scales.

The cutting or assembling of pocketknives may be done mechanically for the mass-produced cheaper products or by hand for the better and more expensive ones. In each case precision is essential, for the blades and other articles incorporated in the knife

must pass each other and always snap into their correct positions, whether open or closed. The spring must be carefully adjusted to achieve this. The cutler himself usually polishes the haft, and other workers glaze, polish and sharpen the blades.

A great variety of pocketknives is made. Most have one or two blades, or one blade and another article. A penknife has blades at both ends. A "lobster" knife has articles at both ends but both sides of the knife are utilized by providing a divided spring known as a lobster spring because of its similarity to the claw of a lobster. A "sports" knife is usually larger and may contain a variety of articles such as a can (tin) opener, a gimlet, bottle opener, corkscrew, screw driver, saw, leather gouge, marlinespike, etc. Special knives are made for particular uses: for example, a gardener's and horticulturist's knife may contain a pruning blade, an implement for budding or a secateur; a yachtsman's knife a marlinespike and a shackler; a fisherman's knife small folding scissors and a file or a disgorging for removing hooks from the mouth of the fish; an electrician's knife an insulation stripper and a screw driver; and for outdoor pursuits a knife may contain a folding saw, can piercer, corkscrew, wire cutters and gralloching blade. Huntsman's or bowie knives are made with fixed or folding blades.

**Care of Cutlery.**—The edge of a knife loses its sharpness as it is used. Stainless and ordinary steel blades should be sharpened regularly with a "steel," carborundum stick or wheel sharpener.

Cutlery, whether it is made of stainless or ordinary steel, should be washed as soon as possible after use and care should be taken to ensure that detergents are dissolved in the hot dish water before cutlery is put into it. At least one of the constituents of some detergents, in the presence of salt, will cause instantaneous corrosion. Prolonged soaking of blades in ordinary water is also a frequent cause of pitting and corrosion. Nonmetallic handles should never be placed in hot water.

Pocket knives and scissors require lubrication regularly at the moving joints.

**The Craftsman.**—In the early 1960s considerable work was being done by hand in the making of better-quality cutlery. In the early part of the 20th century the use of mechanical methods increased and by the middle of the century much of the former toil had been eliminated. Nevertheless, a considerable degree of craftsman skill continued to be essential in the assembling and final processes, especially where natural materials were used for the handles or where metal handles were ornamented. Young craftsmen were trained in the making of accurate tools for the production of the necessary components. Each cutlery-producing country in the western world had a number of highly modern factories in which scientific control and research superseded the "rule of thumb" methods of former years.

Control of the personnel by craft guilds was replaced by governmental regulations coupled with trade associations for employers and trades unions for employees. Special training was organized for young people desiring to enter the industry in the United States, the United Kingdom, Germany and France.

(W. R.; W. G. I.)

**CUTTACK**, a city and a district in Orissa, India.

CUTTACK CITY lies at the bifurcation of the Mahanadi and its main distributary the Katjori. It is 220 mi. S.W. of Calcutta, 45 mi. from the sea, and is served by the South Eastern railway and the Calcutta-Madras National highway. Pop. (1961) 146,590. The city was founded by King Anangabhimha Deva III (1211-38) who built the fort of Barabati and possibly the stone revetment along the banks of the Mahanadi and the Katjori to protect the city from floods of those turbulent rivers. It continued to be the capital of Orissa till the end of the British rule. The fort of Barabati was made into a nine-storied structure by the time of Mukunda Deva (1559-68), the last Hindu king of independent Orissa. The Afghans occupied the city in 1568 but ceded it to the Moguls in 1590. The Marathas got it in 1751 from the Moguls and the British occupied it on Oct. 14, 1803, driving out the Marathas.

Notable monuments in Cuttack city are the Lalbag palace (1633), the Jama Masjid (1690), the Quadam Rosul (1715),

Amarnath temple and the Jain temple (18th century), the Baptist church and the Catholic church (19th century), Barabati stadium (1946) and Sahid Bhavan (Martyrs' memorial). Important educational institutions are Ravenshaw college (1863), founded in memory of T. E. Ravenshaw, the then commissioner of Orissa division, Christ college (1944), Stewart Science college (1944), Shailabala women's college, Sri Ram Chandra Bhanj medical college (1949) and Radhanath Training college, all affiliated to Utkal university, centred in Cuttack. The city also has the Orissa high court and the Central Rice Research institute with a big agricultural farm. Cuttack is famous for filigree and horn work and various cottage industries. At Chauduar to the north there are textile and paper mills as well as a flourishing factory for steel tubes. At Barang to the south there is a glass factory situated between two rivers. Standing at the head of several lines of canals and connected, by roads and railways, to all parts of Orissa, Cuttack is the natural commercial capital of Orissa.

CUTTACK DISTRICT comprises the delta areas of the Mahanadi and Brahmani rivers and a hilly hinterland. Area 4,237 sq.mi. Pop. (1951) 2,529,244; (1961) 3,064,474. Density 723 per square mile. The natural divisions are (1) a marshy salt-impregnated strip 3 to 30 mi. in breadth along the coast; (2) an intermediate rice-producing alluvial plain which stretches inland about 40 mi. and has an extensive system of irrigation; and (3) an upland region with a series of hills running east-west, having wooded slopes and valleys between. The district is intersected by the Mahanadi river with its numerous bifurcations and by the Brahmani, while the Baitarani forms its northern boundary. Staple products are rice and pulses. Jute is also largely grown.

Jajpur on the Baitarani is a noted centre of pilgrimage. It is mentioned even in the Mahabharata (book iii, ch. 85) and it was the capital of several ruling dynasties under different names. Notable antiquities of the place include bodhisattva and Matrika images, a 16-sided monolithic pillar, 33 ft. high, of excellent workmanship, and the mosque of Nawab Abu Nasir Khan (1686). To the south lies the Assia range comprising the Udayagiri, Lalitagiri, Almgiri and Ratnagiri hills, which are famous centres of Buddhist art. Excavations at Ratnagiri (1958) brought to light a magnificent Buddhist monastery of early medieval times.

(MA. M.; N. K. S.)

**CUTTLEFISH**, a name given to a large group of marine cephalopod mollusks related to the octopuses and squids. The term properly denotes any member of the family Sepiidae, especially *Sepia officinalis*, the common cuttlefish of Europe. The most characteristic feature of sepiids is a thick, internal, calcified shell, the cuttlebone of commerce.

**Distribution.**—The sepiids or true cuttlefish include, besides the large genus *Sepia*, *Sepiella*, *Hemisepius* and a few other genera. The sepiids are confined to the old world, no member of the family occurring in North or South American waters. A squid, *Sepioteuthis sepioidea*, that superficially resembles a cuttlefish has often been recorded as such in the literature, but it possesses a thin, horny internal shell (gladius) instead of a calcified one.

About 100 species of cuttlefish are known. They are found in most tropical and temperate seas but are uncommon in colder waters. They are distributed throughout Asia; the Indo-Malayan region and the Japanese islands possess a large number of species. G. Grimpe states that the European species are not found north of the Skagerrak, the arm of the North sea south of Norway. *Sepia pharaonis* and *Sepia latimanus* are widespread Indo-Pacific species. *Sepia officinalis*, the best known of the European cuttlefish, attains lengths of about two feet. The genus *Sepiella*, consisting of

FIG. 1.—COMMON EUROPEAN CUTTLEFISH (*SEPIA OFFICINALIS*), TOP VIEW

smaller cuttlefish, is distributed from Africa to Japan. *Dorotosepion* is a poorly known subgenus of squidlike sepiids.

**Form and Function.**—Cuttlefishes have a somewhat flattened body, edged by a pair of narrow fins extending from the head to the tail end. In the common cuttlefish the mantle is ornamented with zebra-like stripes. The remarkable *Sepiella ornata* has a series of longitudinal patches ("ocelli") along each side. All cuttlefish have ten appendages, eight arms and two tentacles, encircling the mouth. The tentacles, specialized for capturing prey, are longer than the arms and can be withdrawn into two pouches. The suction discs or suckers are arranged transversely in rows of four along the entire length of each arm, except in one of the ventral arms of the male (the "nuptial" or hectocotylized arm), from which they are absent toward the base. On the tentacles the suckers are restricted to an expanded pad or club at the tip.

Cuttlefish are active animals. They usually swim by means of the fins, which perform undulating movements, aided by slow jets from the funnel. On being alarmed or attacked, however, the animal can violently dart backward by expelling a jet of water from the mantle cavity through the funnel. In common with the majority of the Cephalopoda, the cuttlefish secretes an "ink" (see below), the value of which as a means of protection is discussed in the article CEPHALOPODA.

**Natural History and Reproduction.**—Cuttlefish are inhabitants of shallow, coastal waters; however, they usually migrate to deeper waters during the winter. The common cuttlefish breeds during spring and summer in shallow water. The eggs, about  $\frac{1}{2}$  in. long, are coated at spawning with a tough capsule that is darkened by ink from the ink sac. About 100–300 eggs are laid in a season; they are attached in clusters to submerged branches, coral fragments, tubes of marine worms and underwater growths in general. Newly hatched *Sepia*, as big as their eggs, are immediately capable of swimming and feeding. Grimpe studied cuttlefish in captivity and found them monogamous, i.e., the pairs mated for life; however, this does not appear to be the case in nature.

*Sepia* feed mainly upon crustaceans, small fish and even upon each other. D. P. Wilson has described the feeding habits of *Sepia officinalis* in the aquarium of the Plymouth Marine Biological laboratory in England. Upon sighting its prey, such as a shrimp, the cuttlefish undergoes remarkable colour changes; it

then stalks the victim, closing in until the prey is within reach of its tentacles. The latter suddenly shoot out—quicker than the eye can see—and pull the shrimp to the embrace of the sessile arms that convey it to the beaks. Apparently the main enemies of cuttlefish are sharks, whales, porpoises and dolphins, in all of whose stomachs they have been found. Large fish also feed upon them.

**Economic Importance.**—Cuttlefish are eaten in many parts of the world. In China, they form an important fishery and thousands of tons are landed annually. They have also been eaten for centuries in Italy and Greece, and large numbers are canned in Spain and Portugal. In the Mediterranean, cuttlefish are most often caught on artificial lures or by the use of night lights that attract them to the surface. During the breeding season, the Neapolitan fishermen tow a female cuttlefish behind the boat in order to catch the males that flock to her.

The ink secreted by these animals is the well-known rich brown pigment, sepia (q.v.). Although it is still used as a water-colour pigment, substitutes are replacing it, since it tends to fade in light.

The cuttlebone or shell has been used, either pulverized or whole, as a dentifrice, for fine polishing, for taking casts in jewelry and metalwork, as an agricultural fertilizer and for pouncing (dusting unsized paper to prevent ink spreading). It is also used medicinally in the far east. It was formerly used as a cosmetic by Roman women of fashion. Its main economic use today is as a dietary supplement providing calcium for cage birds (canaries, lovebirds, etc.). Over 100 tons of cuttlebone are exported annually from Tunisia.

**Relationships.**—The Sepiidae are included in the suborder Sepioidea along with a number of small bottom-dwelling species that have a degenerate horny shell (*Sepiola*, *Rossia*, *Euprymna*) or have lost it completely (*Idiosepius*). The relationship of these bottom dwellers with the true cuttlefish has been determined by a study of their anatomy and embryology. They are short, squat animals with separate, paddlelike fins.

The peculiar bathypelagic genus *Spirula* is also related to the cuttlefish. *Spirula spirula* has an entirely internal, coiled, chambered shell whose main function apparently is hydrostatic, maintaining the animal in a head downward position in the middle depths.

The modern cuttlefish made their appearance in the Miocene epoch (about 21,000,000 years ago). They are undoubtedly derived from a belemnite-like ancestor *Belosepia*, which lived in the earlier Eocene seas. See CEPHALOPODA.

**CUTTS OF GOWRAN, JOHN CUTTS, BARON** (1661–1707), British soldier whose blind recklessness and indifference to enemy fire earned him the devotion of his troops and the nickname of the "Salamander," was heir to an Essex landed family and a man of some wealth. In 1686 he took service under Charles of Lorraine and was present at the storming of Buda (July). In March 1688, still in Europe, he ignored James II's proclamation recalling his subjects in the service of foreign powers; instead he took the colonelcy of a Dutch regiment and accompanied William of Orange on the invasion of England later that year. He served with distinction in the Irish campaign of 1690, and was created Baron Cutts of Gowran in the peerage of Ireland. Promoted brigadier, he was in the thick of the desperate fighting at Steenkirk (1692) and, having been wounded, retired to the governorship (1693–1707) of the Isle of Wight. He returned to active service on the expedition to Brest in 1694 and at the siege of Namur in 1695, where he again distinguished himself by his reckless, romantic bravery. In 1694 he was appointed colonel of the Coldstream guards. He served under the duke of Marlborough in the opening campaign (1702) of the War of the Spanish Succession, and at the siege of Venloo he ordered the Anglo-Irish brigade into a "suicide" assault on the guns of Ft. St. Michael.

DOUGLAS P. WILSON

FIG. 2.—COMMON EUROPEAN CUTTLEFISH (*SEPIA OFFICINALIS*) FEEDING ON A PRAWN: (TOP) APPROACHING, (CENTRE) SEIZING AND (BOTTOM) INGESTING THE PREY

The attack was successful, but Cutts was widely criticized for his apparent indifference to the lives of his men as well as his own, and he was bitterly lampooned by Jonathan Swift in his *Ode to a Salamander*.

Many contemporaries regarded Cutts as a thick-skulled butcher, a man of limited imagination and overweening vanity, who had been startlingly successful in an early act of folly and had no more sense than to keep on repeating it; and it is perhaps significant that despite his great military experience, his social rank and the high regard in which he was held by William III and Marlborough, he was never entrusted with an independent command. Similarly, though he was a member of parliament from 1693 to 1707 and played a small part in the negotiations leading up to the treaty of Rijswijk (1697), he enjoyed no discernible political influence. He fought with customary distinction in Flanders in 1703 and at Blenheim in 1704, then retired from active service in the rank of lieutenant general. In 1705 he was appointed commander in chief in Ireland and one of the lords justices of the kingdom. He died suddenly in Dublin on Jan. 25, 1707, when his titles became extinct. (J. P. K.)

**CUVIER, GEORGES LÉOPOLD CHRÉTIEN FRÉDÉRIC DAGOBERT**, BARON (1769-1832), one of the great French naturalists of the early 19th century, founder of the studies of comparative anatomy and paleontology, was born on Aug. 23, 1769, at Montbéliard. While still a child he copied the illustrations of the works of Buffon, drawing and colouring them with great precision, which stimulated in him an intense interest in natural history. After spending four years at the Academy of Stuttgart, he accepted the position of tutor in the family of the Comte d'Héricy near Fécamp. There he studied marine fauna and fossils. It thus came about that he made the acquaintance of the agriculturist A. H. Tessier who was then living at Fécamp. Tessier wrote strongly in favour of his protégé to his friends in Paris, with the result that Cuvier, after corresponding with the well-known naturalist E. Geoffroy Saint-Hilaire, was appointed in 1795 assistant to the professor of comparative anatomy at the Muséum National d'Histoire Naturelle. The Institut National was founded in the same year and he was elected a member. In 1796 he began to lecture at the École Centrale du Panthéon, and, at the opening of the Institut National in April, he read his first paleontological paper, which was subsequently published in 1800. In 1798 his first separate work, the *Tableau élémentaire de l'histoire naturelle des animaux*, which was an abridgment of his course of lectures at the École du Panthéon, was published; it may be regarded as the foundation and first general statement of his natural classification of the animal kingdom. In 1799 he succeeded L. J. M. Daubenton as professor of natural history in the Collège de France, and in the following year he published the *Leçons d'anatomie comparée*, a classical work in which he expounded his theory of "the correlation of parts" (i.e., the interdependence of functions and structure—as the function of an organ changes, so will its structure). In this production he was assisted by A. M. C. Dumeril in the first two volumes and by G. L. Duvernoy in three later ones.

In 1802 Cuvier became titular professor at the Jardin des Plantes, and in the same year he was appointed commissary of the Institut National to accompany the inspectors general of public instruction. In this latter capacity he left for the south of France; but in the early part of 1803, when he was chosen perpetual secretary of the Institut National in the department of the physical and natural sciences, he abandoned the appointment of commissary and returned to Paris.

Cuvier then devoted himself more especially to three lines of inquiry—one dealing with the structure and classification of the Mollusca, the second with the comparative anatomy and systematic arrangement of the fishes and the third primarily with fossil mammals and reptiles and secondarily with the osteology of living forms belonging to the same groups. His papers on the Mollusca began as early as 1792, but most of his memoirs on this branch were published in the *Annales du muséum* between 1802 and 1815. They were subsequently collected as *Mémoires pour servir à l'histoire et à l'anatomie des mollusques*, published in one volume at Paris in 1817. In the department of fishes Cuvier's researches,

begun in 1801, finally culminated in the publication of the *Histoire naturelle des poissons*, which contained descriptions of 5,000 species of fishes. This work was the joint production of Cuvier and A. Valenciennes, its publication (as far as the former was concerned) extending over the years 1828-31. The department of paleontology dealing with the Mammalia may be said to have been essentially created and established by Cuvier. In this region of investigation he published a long list of memoirs, partly relating to the bones of extinct animals and partly detailing the results of observations on the skeletons of living animals specially examined with a view toward throwing light upon the structure and affinities of the fossil forms.

The results of Cuvier's principal paleontological and geological investigations ultimately appeared in the form of two separate works. One of these is the celebrated *Recherches sur les ossements fossiles de quadrupèdes*, published in Paris in 1812, with subsequent editions in 1821 and 1825; the other is his *Discours sur les révolutions de la surface du globe*, originally published as *Discours préliminaire* to the above. But none of his works attained a higher reputation than his *Le Règne animal distribué d'après son organisation*, the first edition of which appeared in four octavo volumes in 1817 and the second in five volumes in 1829-30. In this classical work Cuvier embodied the results of the whole of his previous researches on the structure of living and fossil animals. He divided animals into four types: vertebrate, mollusk, articulate and radiate. The whole of the work was his own, with the exception of the Insecta, in which he was assisted by his friend P. A. Latreille. Cuvier believed that the extinction of species was brought about by some local catastrophe and that the area concerned was repopulated by types coming in from other parts. He maintained that each species was created for its own special purpose and each organ for one specific function. In this he came into direct opposition with Geoffroy Saint-Hilaire (see GEOFFROY SAINT-HILAIRE, ÉTIENNE).

Apart from his own original investigations in zoology and paleontology Cuvier carried out a vast amount of work as perpetual secretary of the Institut National and as an official connected with public education generally; much of this work appeared ultimately in published form. Thus in 1808 he was placed by Napoleon upon the council of the Imperial university. In this capacity he presided (in the years 1809, 1811 and 1813) over commissions charged to examine the state of the higher educational establishments in the districts beyond the Alps and the Rhine, which had been annexed to France, and to report upon the means by which these could be affiliated with the central university. Three separate reports on this subject were published by him. In his capacity, again, of perpetual secretary of the institute he not only prepared a number of *éloges historiques* on deceased members of the Académie des Sciences, but also was the author of a number of reports on the history of the physical and natural sciences, the most important of these being the *Rapport historique sur le progrès des sciences naturelles depuis 1789*, published in 1810.

Prior to the fall of Napoleon (1814) he had been admitted to the council of state and his position remained unaffected by the restoration of the Bourbons. He was elected chancellor of the university, in which capacity he acted as interim president of the council of public instruction, while he also, as a Lutheran, superintended the faculty of Protestant theology. In 1818 he was elected a member of the Académie Française.

In 1819 he was appointed president of the committee of the interior and retained the office until his death. In 1826 he was made grand officer of the Legion of Honour; and in 1831 he was raised by Louis Philippe to the rank of peer of France, and was subsequently appointed president of the council of state.

In the beginning of 1832 he was nominated to the ministry of the interior, but on May 13 he died in Paris after a brief illness.

**CUXHAVEN** (KUXHAVEN), a seaport of Germany which after partition of the nation following World War II was in the *Land* (state) of Lower Saxony in the Federal Republic of Germany. It lies on the south bank of the Elbe mouth, 133 km. (83 mi.) W.N.W. of Hamburg by road (114 km., or 71 mi., by rail). Pop. (1959 est.) 42,975. Interesting buildings include the 13th-century Ritzebüttel castle containing the museum; the 13th-century St. Abundi church; and the lighthouse (1803). Railways run to Hamburg and Bremen. Cuxhaven is a leading pilot station and a fishing port with a large fish market. Shipbuilding and fish canning are carried on. The town is also a tourist centre. Part of the county of Stade during the middle ages, Cuxhaven was conquered by Hamburg in 1394 and remained under that port until united with Hanover in 1937. In World War II it was captured by the Allies in May 1945. (W. J. H. H.)

**CUYAHOGA FALLS**, a city of Summit county, O., U.S., is located on the Cuyahoga river, 5 mi. N.E. of Akron. Founded in 1812, it was incorporated as a village in 1868 and as a city in 1921. It began as a mill town, using the power of the Cuyahoga river at a place where it falls more than 100 ft. in one mile. Local coal supplemented the water power for a time, but was soon exhausted. Small industries, including a flour mill, a paper mill (the first west of the Allegheny mountains), a clay products plant (until local clays were exhausted), a rolling mill and a wire mill, succeeded for a time, then were discontinued. During World War I the demand for rubber tires for motor vehicles was so great that that industry, in Akron, recruited workers from Cuyahoga Falls. The Akron transit system included Cuyahoga Falls in its local service, and while the city has some important manufactures, including machinery, tools and dies, plastics and rubber products, it became primarily a residential suburb.

A municipal park of several acres, located on the east side of the river, includes a swimming pool where the National Swimming meet, regional meet of the Amateur Athletic union, has been held several times. The city supports a civic art centre, and a civic music association. For comparative population figures *see* table in OHIO: Population. (E. G. WE.)

**CUYP**, the name of a family of Dutch artists, settled in Dordrecht, or Doort, during the 17th century, of which seven members in three generations were painters. The family was largely employed in glass painting, but produced in Aelbert Cuyp (*see* below) one of the great masters of landscape painting in oils.

**GERRIT GERRITZ CUYP**, the Elder (d. 1644), the founder of the family, came originally from Venlo, and entered the Dordrecht Guild of St. Luke as a glass painter in 1585. In the same year he married, and of six children of this first marriage, two sons, Abraham and Jacob, were painters. His first wife died in 1601, and he married again in 1602. Two more sons, Gerrit and Benjamin, grew up to be artists. Gerrit Cuyp, the elder, died at Dordrecht in 1644.

**ABRAHAM GERRITZ CUYP**, the dates of whose birth and death are unknown, was the eldest son of Gerrit Gerritsz, the elder. He, too, was principally a glass painter. He married in 1612 and died before 1644. His son, **JACOB ABRAHAMZ CUYP**, followed in his steps as a glass painter, being admitted to the Dordrecht guild in 1636.

**JACOB GERRITZ CUYP** (1594–after 1651), best known for his portraits, was the second son of Gerrit Gerritsz, the elder, and father of Aelbert. He was born at Dordrecht in Dec. 1594. He broke with the family tradition of glass painting, and painted historical pictures, portraits and animal subjects. He entered the Dordrecht Guild of St. Luke in 1617. According to A. Houbraken, he had studied under Abraham Bloemart in Utrecht, and this is probably true, since he married a girl from Utrecht in 1618. He was a man of substance in Dordrecht, and held various offices in the guild.

There are examples of Jacob's portraits in many of the principal European galleries. They are soundly painted, sure in draftsmanship and firm in modeling, and though they lack the vitality of a Hals or the insight into character of a Rembrandt, they are imbued with that honesty and integrity which, allied to technical competence, are characteristic of the best tradition of Dutch painting.

Besides many simple bust or half-length portraits on a monochrome background, he painted some full-lengths, including several pleasing portraits of children, and some more ambitiously designed group portraits, with interior or landscape backgrounds. There are fine single portraits of women in Amsterdam, Berlin and Vienna, and a pair of a husband and wife in Budapest. An interesting but not very successful experiment is the double full-length portrait of "A Young Couple as Damon and Phyllis" in Berlin, in which a stolidly Dutch husband and wife are represented as a shepherd and shepherdess with their sheep in an Arcadian landscape. Far more suited to the temperaments of the painter and his sitters is the delightful "Family Group" in the Rijksmuseum, Amsterdam, which portrays a man and his wife, an elderly woman, five children, a pet goat and a horse and trap, in front of a house which stands, surrounded by trees, in a level landscape. As a painter of animal subjects and landscapes, Jacob undoubtedly exerted a powerful influence on his more famous son, for there is a degree of atmosphere and luminosity in his work unusual among the painters of his generation. Indeed, it is likely that several of his landscapes with herdsmen or shepherds and their animals are still wrongly attributed to Aelbert. Of his work in this vein there is an example, dated 1628, in Amsterdam. Jacob Cuyp died soon after 1651.

**GERRIT GERRITZ CUYP**, the Younger (born 1603), third of the artist sons of Gerrit Gerritsz, the elder, entered the guild at Dordrecht as a glass painter in 1631, at the same time as his younger brother, Benjamin. He moved from Dordrecht in 1644.

**BENJAMIN GERRITZ CUYP** (1612–1652), youngest son of Gerrit Gerritsz, the elder, was born at Dordrecht in Dec. 1612. Houbraken states that he studied under his uncle, Jacob Gerritsz. He was admitted to the guild in Dordrecht in 1631. Benjamin Cuyp was a painter of some talent, and had a large output in a short life, including landscapes, genre scenes, biblical subjects and battle pieces. His characteristic style, in which he employs a powerful *chiaroscuro*, appears to have been influenced by Rembrandt. He died on Aug. 28, 1652, at Dordrecht.

**AELBERT JACOBZ CUYP** (1620–1691), famous for his landscapes in oil, was baptized at Dordrecht on Oct. 20, 1620. After the death of his father, Jacob Cuyp, soon after 1651, and of his mother in 1654, he came into a considerable property, and was a leading citizen in the affairs of the town. In 1658, he married Cornelia Boschman, a well-connected widow with three children, who in the following year bore him his only child, a daughter. He sold his father's house on the Niebrugge in 1659, and in 1663 moved into the house in the Wijnstraat which he occupied, together with a property at Dordwijk, until shortly before his death. Apart from records of his name in the archives of Dordrecht, where he held a variety of civic offices, the known facts of his life are extremely sparse.

It is reasonable to suppose that, as Houbraken says, he first studied under his father, whose influence is visible in both the style and the subject material of his art. Whether he also studied under Jan van Goyen, with whom his early style has much in common, remains a subject of speculation. He does not appear ever to have traveled far from Dordrecht, but from the internal evidence of his pictures we may presume that he knew the country around Nijmegen, and that at some period he journeyed farther up the Rhine or Meuse to reaches where the banks are hillier and more picturesque than in the neighbourhood of his native town. The theory that he worked for a while in Utrecht, though it cannot be substantiated, provides a plausible explanation of the Italianate elements in his mature style, the feeling for simple and noble form, and the warm, rich rendering of atmosphere.

In Utrecht, the artistic centre which, more than any other in Holland, looked to Italy for its stylistic nourishment, he would have known the work of Jan Both, a direct link with Cuyp's only peer in the 17th century as a painter of light and atmosphere, Claude Lorrain. As a portrait painter, Cuyp follows the example of his father. Though many portraits are attributed to him, only the "Portrait of a Man" in the National gallery, London, can be assigned to him with certainty.

Cuyp did some pictures of animals and domestic birds, influencing such younger artists as Johannes Spruyt, and an occasional history piece, but by far the most numerous and important branch of his art is the landscapes. Cuyp signed many but dated few of his paintings, and it is difficult to establish a chronology of his stylistic development. However, it is clear that up to the early 1640s he painted usually on a small scale, in a style deriving partly from his father and partly from Jan van Goyen. These are mostly landscapes with cattle and figures, executed with a small, firm but flowing touch. An example, dated 1639, is in the museum at Besançon, and another, of a "Castle by a River Bank," in the Liechtenstein collection, Vienna.

To the later 1640s and 1650s belong most of his finer and more typical works, the views of the banks of the Maas and Waal near Dordrecht, with shipping on calm waters, or resting cattle silhouetted against an evening sky, and the bolder Rhenish landscapes, with groups of horsemen or peasants. Whether the composition is simple or expansive, he bathes these subjects in a subtle glow of light, a poetry of atmosphere that is unmatched among his contemporaries. It is the soft, gray light of early morning or the soft, golden light of evening, and his characteristic colour harmonies are based on luminous grays and golds, with accents of red, warm brown or black. Enveloped in atmosphere as if imprisoned in pale amber, the forms of cattle, ships and the distant towers of Dordrecht have a timeless, monumental quality rare in northern art. Some larger and more artificial compositions, in which this spirit of delight in simple nature becomes diluted, probably belong to the later years of his activity in the 1660s. During the last 20 years of his life he probably painted little or nothing at all.

Albert Cuyp died at Dordrecht in Nov. 1691. There is room for much research into his work, particularly into the distinction between his own work, that of other members of his family and that of his one close follower, Abraham Calraet, whose signature, "A.C.," was long mistaken for a variant of his own. Cuyp is well represented in galleries throughout Europe and North America, but a remarkable proportion of his best works are, or were once, in England, where the aristocratic collectors of the 18th century appreciated his qualities much earlier than their counterparts in other countries. Many works of outstanding excellence are still in British private collections.

See H. de Groot, *A Catalogue of Works of Dutch Painters*, vol. ii (1909); F. Cundall, *The Landscape and Pastoral Painters of Holland* (1891).

(R. E. W. J.)

**CUZA, ALEXANDRU ION** (1820–1873), prince of Rumania from 1859 to 1866, was born at Husi, Moldavia, on March 20 (new style; 8, old style), 1820, a descendant of an old boyar family. In his youth he came into contact with the progressive ideas of his time. He studied in Paris, Pavia and Bologna and took part in the 1848 revolutionary movement in Moldavia. On Jan. 17 (N.S.; 5, O.S.), 1859, he was elected prince (*hospodar*) of Moldavia and on Feb. 5 (N.S.; Jan. 24, O.S.), prince of Wallachia. His double election brought about the unification of the two Rumanian principalities. (See *RUMANIA: History*.) Cuza's reign saw some useful reforms in agrarian and electoral law and in public education. New civil and penal codes were introduced and a court of audit founded. The properties of monasteries were nationalized. These democratic reforms did not please the ruling landowner class. A military conspiracy engineered by great landowners, with some sympathy from a section of the bourgeoisie, forced Cuza to abdicate on Feb. 23, 1866, and to leave the country. Cuza died in Heidelberg on May 15, 1873.

See Paul Henry, *L'Abdication du Prince Cuza et l'avènement de la dynastie de Hohenzollern au trône de Roumanie* (1930).

(G. G. Bu.)

**CUZCO** (Cusco), a department in southern Peru, bounded on the north by Loreto, on the east by Madre de Dios and Puno and on the southwest by Arequipa, Apurímac, Ayacucho and Junín. The area is 32,487 sq.mi., and the population (1961) 614,299. Most of the department lies within the Andes mountain range, with much of its land over 11,000 ft. in altitude. The chief ranges of high mountains are the Cordillera de Vilcanota, the Cordillera

de Carabaya and the Cordillera Vilcabamba. The department is drained by the Río Apurímac and the Río Urubamba. The capital city, Cuzco (*q.v.*) occupies a basin a little south of the Río Urubamba at an elevation of over 11,000 ft.

Most of the inhabitants of Cuzco are farmers or herders. The farmers are concentrated along the upper Urubamba around Sicuani, and in the basin of Cuzco and nearby Anta. At elevations between 11,000 and 14,000 ft. the chief crops are potatoes, barley, wheat and maize. At lower elevations along the Urubamba, farmers grow sugar cane, cotton, coffee, cacao, rice and coca. A large part of southern Cuzco is used for the pasture of sheep and alpacas. There is some mining of gold and silver and other minerals. The department was formed in 1822.

(P. E. J.)

**CUZCO** (Cusco), a city in south central Peru, capital of the department of the same name. Pop. (1961) 78,289. It stands at 11,207 ft. above sea level in lat. 13° 31' S. at the west end of Cuzco valley, a basin extending 20 mi. E. to Huamantla. It is watered by the Huatanay river, a tributary of the Vilcanota. The air is dry and frost is rare even during the coldest months, June and July. Rainfall is about 32 in. annually, the rainy season being from November to mid-March. The average annual temperature is 51.2° F. with a range of about 7°.

As capital of the Inca empire, dating from the 11th century (see *ANDEAN CIVILIZATION*), Cuzco was the political centre of an empire extending southward from Quito to the Maule river in the present Republic of Chile. The population of the empire at the time of the Spanish conquest may have numbered 10,000,000. Cuzco and the surrounding area contain extensive pre-Inca and Inca ruins that reflect unusual competence in engineering, stonework and architecture. The architecture of the Incas comprised fortresses, religious sanctuaries and dwellings. Construction resembling the configuration of the Andes and the pyramidal shape was characteristic of the architectural style. Entrances, recesses and openings in general were in the form of a geometrical figure with sides narrowing toward the top.

Francisco Pizarro (*q.v.*) took possession of Cuzco in the name of Emperor Charles V in March 1534, inaugurating the colonial history of the city. Most of the Incan structures were demolished and replaced with Spanish edifices. The city was largely destroyed by an earthquake in 1650 but was rebuilt. During the colonial period, under the influence of strong religious spirit, Cuzco was the centre of a notable and prolific artistic production, mainly painting, sculpture, jewelry and ornamental woodworking.

Significant religious and public buildings of colonial origin include the cathedral, completed in 1654 upon the site of the Inca palace of Huiracocha, the National University of Cuzco, founded in 1692, and a number of churches, convents and monasteries. Evidence of the pre-Inca and Inca civilizations is prevalent throughout the city in the form of foundations of the Spanish structures, walls of fine stonework and the remains of the Temple of the Sun. In the environs of Cuzco are situated the fortress of Sacsahuamán, one of the great achievements of primitive man, the Inca bath, or Tombomachay, the Kenco amphitheatre, the Inca throne and lesser ruins. The citadel of Machu Picchu, "The Lost City of the Incas," is accessible by rail from Cuzco. In May 1950 Cuzco was badly shaken by an earthquake that damaged many of its old buildings and churches.

As capital of the department, Cuzco is the official residence of the highest administrative and ecclesiastical officials in the area. Potatoes and grains are cultivated for local consumption, and sheep, alpaca and llama are grazed there. Important local industries are the production of cloth, rugs, tapestries and fine metalwork. The population is chiefly Indian and mestizo. Cuzco is reached from the port of Mollendo by the Southern Railway of Peru and is connected with Lima by a motor road and an airline.

(J. L. Tr.)

**CWMBRAN** ("valley of the crow"), a New Town mainly in the Cwmbran urban district and partly in the Pontypool rural district of Monmouthshire (*q.v.*), lying about 5 mi. N. of Newport. Through the town from north to south run two railway lines, the fast-flowing Afon Lwyd and the disused Monmouthshire and Brecon canal, while along its eastern edge is the Newport-

Abergavenny trunk road. The area, designated as one of the New Towns (*q.v.*) in 1949, partly because of good rail and road communications, covers 4.9 sq.mi., and had a population of about 13,000. Development began in 1951 and by 1961 the population had risen to 21,690, the proposed final population being 55,000.

Coal was formerly mined in the area and the older industries comprise a foundry, tinplate and brick works (using the local red marl). After 1939 a greater diversity of employment was achieved by the establishment of factories for making brake linings, valves, dairy machinery and biscuits (cookies), and in the mid-1950's a large bakery and a milk distribution centre were set up. Nearby are steelworks and glass, nylon and ordnance factories.

**CYANAMIDE, CALCIUM**, is an organic chemical ( $\text{CaNCN}$ ), sometimes referred to simply as cyanamide, commercially important as a fertilizer and as the parent substance of many chemical products. When used as a fertilizer, its nitrogen is changed in the soil to the ammonia form and, as such, it is very resistant to leaching. Its lime supplies soluble calcium as a plant nutrient and corrects soil acidity.

On contact with soil moisture, calcium cyanamide is hydrolyzed to form free cyanamide, which is highly toxic to vegetation but is rapidly converted to the ammonium form. Harm to crop plants or seeds is avoided by placing calcium cyanamide deep in the soil before planting so that the necessary chemical changes are complete before the seedling roots have contact with it. If, because of special cultural operations, it is necessary to place the cyanamide close to the row of seeds or plants, the application should precede planting by a few days.

Economic advantage is taken of the temporary toxic properties of calcium cyanamide for the control of certain weeds and soil-borne diseases. To kill the broad-leaved annual weeds in small grain crops, only 100 lb. per acre of the pulverized form need be dusted on the plants when they are quite small. Two and one-half to three tons per acre of the granular form of cyanamide, worked into the soil three or four months ahead of seeding, are used to kill weeds in tobacco and vegetable transplant beds. Sclerotiniase, a fungous disease of certain vegetable crops, is often controlled by applying one-half ton per acre of calcium cyanamide.

Calcium cyanamide is the active ingredient in a chemical dust which, when used at only 35 lb. per acre, will cause defoliation of cotton and certain other plants, preparatory to harvest.

Calcium cyanamide has assumed considerable importance in the chemical industry as a raw material for the preparation of numerous products. Calcium cyanide is made on the large scale from calcium cyanamide. Other products of commercial importance derived from calcium cyanamide are dicyanodiamide, melamine and guanidine derivatives (*see* HYDROCYANIC ACID).

Calcium cyanamide has found limited use as a carburizing agent in the steel industry. A more important potential use appears to be the desulfurization of iron, to replace calcium carbide, the use of which presents certain serious hazards.

A valuable plastic is made by the condensation of melamine with formaldehyde. This is used very extensively in the form of a laminate in the manufacture of table tops, furniture, wall panels and the like. It is also used for the manufacture of molded articles, especially tableware. It is noted for its great decorative value and its excellent lasting qualities. Partial condensation products of melamine and formaldehyde are used for imparting wet strength to paper used for the preparation of towels, napkins, shipping bags, food wrappers, tea bags and photographic and blueprint paper. A special methylated melamine resin is used in textile finishes for imparting wrinkle resistance to cotton goods, a woollike texture to spun rayon, and for shrinkproofing wool. The resin is also used for tanning white leather. A butylated melamine resin is used widely in protective and decorative coatings for automobiles, refrigerators, etc.

**Manufacture.**—Commercially, calcium cyanamide is made from calcium carbide and nitrogen. The process was the outgrowth of an extended series of experiments by Adolf Frank and Nikoden Caro, begun in 1895 and aimed at the development of a process for the fixation of atmospheric nitrogen. These investigators discovered that commercial calcium carbide, though not the pure

carbide, reacts readily with nitrogen at temperatures in excess of 800° C. The reaction of calcium carbide with nitrogen, which takes place according to the equation  $\text{CaC}_2 + \text{N}_2 = \text{CaNCN} + \text{C}$ , is exothermic. The rate of reaction and the degree of conversion increase with increase in temperature. Decomposition of the cyanamide takes place at temperatures in excess of 1,200° C., and at 1,400° C. loss of calcium and nitrogen becomes appreciable. The optimum reaction temperature would appear to be 1,100°–1,130° C. Calcium chloride, or a mixture of calcium chloride and calcium fluoride, has been used as a catalyst to facilitate the reaction.

The nitrogen used in the preparation of calcium cyanamide is obtained by fractionally distilling liquid air, by the Linde or Claude process, and should be at least 99.7% pure. The carbide is ground to a fine powder in an inert atmosphere.

**Discontinuous Process.**—The greater part of calcium cyanamide produced commercially is made by a discontinuous process originated by Frank and Caro. In the more modern works, ovens of four to ten tons in capacity are used. One large manufacturer makes use of more than 1,000 such units. The ovens consist of an iron casting internally insulated with diatomaceous earth and firebrick. A heavy paper cylinder is placed in the oven cavity to receive the carbide. A small amount of fluorspar is mixed with the carbide; this acts both as a catalyst and as a regulator of the reaction. The oven is closed with an insulated cover made tight with a sand seal. The heating electrode is inserted through a central hole in the cover into a tubular opening in the centre of the charge, and it makes contact with a grounded graphite block at the bottom. Nitrogen is admitted to the oven through the bottom and also through the side. The reaction is initiated by heating the centre of the charge to about 1,000°–1,100° C. by the passage of an electric current through the electrode. Thereafter the reaction proceeds automatically until the entire charge is azotized; complete azotization may require 24–40 hr. The azotized mass is removed from the ovens and transferred to a storage room where it is allowed to cool in an inert atmosphere.

**Continuous Processes.**—In the Polzenius-Krauss process the carbide, mixed with 10% calcium chloride, is charged in perforated iron vessels mounted on trucks which are moved through a tunnel filled with nitrogen. A section of the tunnel is externally heated; there the charge is brought to the reaction temperature. The next section is provided with controlled air-cooling which serves to maintain the proper reaction temperature. The last section serves as the cooling chamber.

The Carlson oven consists of a vertical iron shaft about 70 ft. high, lined with firebrick and divided internally into sections by shelves. The carbide mixed with fluorspar is fed in at the top and is heated to the reaction temperature as it passes through an arc between carbon electrodes. It meets an ascending stream of nitrogen and is made to fall slowly from shelf to shelf by scrapers until it is discharged at the bottom.

The cooled lump cyanamide is ground to a fine powder and the powder is treated with just sufficient water to decompose the residual carbide and to hydrate the calcium oxide present. To prevent dustiness, the powder is oiled or granulated by moistening with the proper quantity of water or solutions of various salts, compressing and comminuting the resulting flakes to the desired size.

In the kiln process of Knapsack, granular carbide mixed with 50% calcium chloride is introduced into a rotary kiln, while a stream of pure nitrogen is passed in a countercurrent direction. The material remains in the kiln a total of about 24 hr. The heat of reaction is sufficient to maintain the temperature at the desired level. Control of temperature is achieved by regulating the flow of nitrogen through the kiln. This process produces cyanamide in the desired granular form.

**Pure Calcium Cyanamide.**—White calcium cyanamide analyzing 92% actual is obtained when a mixture of ten parts of ammonia and two parts of carbon monoxide by volume is passed over calcium carbonate heated to 750° C.

**Free Cyanamide.**—Free cyanamide,  $\text{H}_2\text{NCN}$ , is a white solid melting at 46° C. It is unstable and gradually polymerizes to its dimer, dicyanodiamide,  $\text{H}_2\text{NC}(=\text{NH})\text{NHCN}$ . Polymerization proceeds more rapidly in aqueous solution in the presence of al-

kalies. The reaction may occur with explosive violence. Polymerization is apparently the result of the reaction of undissociated cyanamide,  $\text{H}_2\text{NCN}$ , with the cyanamide ion,  $\text{HNCN}^-$ . The lack of stability of cyanamide is shared by monosubstituted cyanamides, such as  $\text{CH}_3\text{NHCN}$ , but disubstituted cyanamides, such as  $(\text{CH}_3)_2\text{NCN}$ , are comparatively stable. (V. M.; X.)

**CYANIDE:** see HYDROCYANIC ACID.

**CYANIDE PROCESS**, the best-known and most widely adopted method for extracting gold and silver from their ores. It comprises the steps of contacting the finely ground ore with a weak cyanide solution as a solvent, separating the solids from the clear solution and recovering the metals in the form of a black precipitate by means of zinc dust.

Invented in 1887 by J. S. MacArthur and R. W. and W. Forrest, the process is remarkable because of the nature of the solvent—a highly poisonous compound; the effectiveness of extremely weak solutions (0.01% to 0.10% potassium cyanide, KCN, equivalent); and because it made possible the economic treatment of large tonages of low-grade ore (0.2 oz. per ton in South Africa).

This process had a tremendous impact on the gold mining industry, which, in spite of the rich discoveries on the Rand in the Transvaal, South Africa, in the 1880s, was obtaining poor extractions by the amalgamation and gravity concentration processes then available. At first the cyanide process was used mainly for the treatment of tailings from amalgamation, but later it replaced amalgamation altogether in the Transvaal and in the majority of plants the ore is cyanided directly. Various steps usually are taken to recover the coarse gold or silver before it enters the cyanide plant (to minimize the treatment time) and some plants employ concentration by flotation with cyanidation of the concentrates and occasionally the tailings as well. Roasting the concentrates before cyanidation often is necessary in cases where the precious metal is associated with arsenic, antimony or sulfotellurides. Directly or indirectly, however, much of the world's gold supply is dependent on the cyanide process. In the United States more than one-third of the gold produced is as a by-product of base metal ore; in the case of silver a very large part of its production results from the smelting of base metal ores (see COPPER; LEAD).

**Chemistry.**—The chemistry of cyanide solutions is extremely involved due to side reactions with various elements present in the ore but it is known that both gold and silver are dissolved as double cyanides of the precious metal and the alkali metal. Expressed in chemical symbols, it is generally agreed that the following equation represents the dissolving action (for gold):

and the precipitation with zinc dust:

It will be noted that in the dissolving reaction oxygen is required, and in plant operation care is taken to see that the solutions are well aerated during this step. In the precipitation reaction the presence of free sodium cyanide is an important consideration. The solutions are first deoxidized by vacuum treatment. Silver reacts with sodium cyanide to form a water-soluble sodium silver cyanide from which the silver is precipitated by treatment with zinc dust. (See also GOLD: Other Compounds; SILVER: History.)

FIG. 1.—SECTION OF TUBE MILL SHOWING HOW THE BROKEN GOLD ORE, SCREENED TO A MAXIMUM SIZE OF  $\frac{1}{2}$  IN., IS GROUND WITH PEBBLES OR UNBROKEN ORE TO A MIXTURE OF SAND AND SLIME

**Crushing and Cyaniding the Ore.**—The initial stages of crushing are carried out in jaw or gyratory-type crushers, and then the ore is delivered to the wet grinding mills after passing screens having about a  $\frac{1}{2}$  in. square opening. In most parts of the world cylindrical mills partly filled with steel balls are used in the wet grinding operations, but tube mills charged with pebbles or mixed loads of pebbles and balls (fig. 1) are still used extensively on the Rand because of the nature of the ore. A grinding mill consists of a steel cylinder, provided with suitable liners, placed in

BY COURTESY OF DORR-OLIVER INC.

FIG. 2.—CUT-AWAY VIEW OF HYDROCYCLONE

a horizontal position and made to revolve on its own axis. The grinding charge (flint pebbles or pieces of unbroken ore in the case of a tube mill) rolls through and over the mixture of ore and solution which is fed to the mill continuously and grinds it to a mixture of sand and slime. This product is discharged to a classifier, the purpose of which is to separate out the particles of ore that are crushed to the desired fineness and return the oversize to the mill. A number of machines are used for this closed-circuiting operation including the stationary cone classifier, Dorr rake classifier, the Akins and Wemco spiral classifiers, and the hydrocyclone, which operates on the same principle as the dry dust collector and is illustrated in fig. 2. While the latter have the advantage of simplicity and lower capital investment, operating and maintenance costs are higher as compared with mechanical classifiers. (See also ORE DRESSING.)

**Batch Treatment.**—The cyanide process up to the early 1900s was a batch process and separate sand and slime treatments invariably were used. While this system is still used to some extent, the majority of plants operate on a continuous basis, called all-sliming. Where sand is separately treated the ore is ground in water and the sand is separated from the slimes in a classifier, discussed above, and discharged into large circular vats with filter bottoms. After draining off the water, cyanide solution is pumped on top, dissolving the gold as it sinks through the sand bed, and is drawn off at the bottom. Oxygen is supplied by periodically draining the charge completely. The sand tailings are then discharged either manually or mechanically through bottom ports,

and the vat readied for another charge.

The slime portion of the ore was originally treated by paddle agitators alone, then compressed air was introduced through tubes reaching to the bottom of the tanks and later by air lifts in tall, cone-bottomed tanks, of which the Pachuca tank (fig. 3), used on silver ores at Pachuca, Mex., is the best known. Air is forced into the central tube at the bottom and bubbles up the tube carrying the slime with it. The latter overflows at the top and recirculates to the bottom of the tube repeatedly, the aeration and mixing continuing until the metal is dissolved. The whole content of the tank is then pumped to the filter section (*see below*). The Dorr agitator (fig. 4), in general use in most plants, combines aeration with mechanical agitation by means of slowly revolving rakes attached to, and driven by, a central shaft.

#### Continuous Treatment.—

The invention of the Dorr thickener in 1905 brought continuous treatment to the industry with its many attendant advantages. While certain attempts had previously been made to settle and wash the slimes by repeated decantations, the method was cumbersome and inefficient compared with the system of countercurrent decantation which the continuous thickener made possible (fig. 5). In this system the slime is pumped through a series of thickeners while the clear overflow moves in the reverse direction, starting with wash water which is mixed with the incoming thickened pulp flowing into the last thickener and ending with the rich (pregnant) solution overflowing the first thickener of the series. The solids finally discharged are practically free of gold-bearing solution and 98%–99% washing efficiency is not unusual.

**Filtration and Gold Recovery.**—In the batch treatment system, after the gold has been dissolved the next step is to pump the mixture of solids and solution to vacuum filters. The earliest large-scale filtering operations were performed in Moore type and Butters filters, the latter still being used in some Rand plants. Filter presses were also tried but have survived in only one, and in this respect unique, operation in the United States.

Both Moore and Butters filters employ large numbers of closely spaced filter leaves or frames immersed in a rectangular tank with a V-bottom. Each leaf consists of a vertical frame supporting

FIG. 3.—SECTION (INCOMPLETE) OF A PACHUCA AGITATING TANK

The slimed ore is charged with air while the gold is being dissolved. Aeration is an important factor in the solution of gold by the cyanide process.

FIG. 5.—CUT-AWAY VIEW OF CENTRE-PIER THICKENER

a canvas bag that is wide and deep but nearly flat. A vacuum is applied to the inside of the frame, so that the solids form a cake on the outside while the clear solution is sucked through. The principal difference between the Moore filter and the Butters lies in the method of washing and discharging the cake of solids. In the former, a whole block of frames is removed from the tank and lowered into a second tank where they are given a water wash and

BY COURTESY OF DORR-OLIVER INC.

FIG. 6.—OLIVER DRUM FILTER

finally discharged by breaking the vacuum and applying compressed air to the bags. In the Butters filter the frames are stationary, and washing, transfer and discharging operations are performed by centrifugal pumps.

Just as the Dorr thickener brought about continuous decantation, so the invention in 1907 of the segmental rotating Oliver drum filter (*see fig. 6*) made continuous filtration and washing possible. Not only is it common practice to employ drum filters for dewatering the final underflow from a countercurrent decantation system, but plants using several stages of countercurrent filtration are to be found in various parts of the world. The drum surface is covered with a number of separate filtering elements, each of which connects to ports on a multiple-opening circular valve attached to the central shaft. The drum is partially submerged in the solids-solution mixture and a vacuum applied during the time each filter section is submerged and continued until just before it reaches the discharge blade, at which point it is cut off and compressed air applied to assist discharge of the cake. Wash water in the form of sprays can be applied before the cake passes the uppermost point in the draining cycle.

For the recovery of gold or silver from the cyanide solution,

BY COURTESY OF DORR-OLIVER INC.

FIG. 4.—CUT-AWAY VIEW OF DORR AGITATOR

the dissolved air is first removed by applying a vacuum to thin streams of the liquid in a closed tank (Crowe process). A regulated flow of zinc dust is then added to the deaerated solution, and the gold or silver precipitated as slime (not to be confused with the ore slime mentioned previously), while most of the zinc is dissolved. The slime is then collected in vacuum or pressure-type filters, and the clear solution pumped to a storage tank for re-use in the plant. The slime is purified by furnace methods and is finally melted and cast into bars.

**CYANITE:** see **KYANITE.**

**CYAXARES** (d. c. 585 B.C.), king of Media, reigned 40 years according to Herodotus (book i, 106); i.e., from c. 625–585 B.C. The Babylonian Chronicle calls him Umakishtar; his Iranian name was probably Huvakhshtra. Herodotus narrates that he renewed the war against the Assyrians after his father, Phraortes, had been slain in battle and that, while he besieged Nineveh, he was attacked by a great army of Scythians. According to Herodotus, the Scythians defeated Cyaxares and ruled Media for 28 years (652–625), till their chiefs were slain by Cyaxares at a banquet. It was probably Cyaxares, not his father, Phraortes, as is maintained by Herodotus, who united the tribes of Iran. He also reorganized the Median army, which hitherto had consisted of tribal and local levies, and once more renewed the war against Assyria. In 614 the Medes took Ashur and in 612, aided by the Babylonians under Nabopolassar, occupied and sacked Nineveh. About the same time they seem to have conquered the kingdom of Manna in modern Iranian Azerbaijan, and in 609 invaded and afterward subjected Urartu in the Armenian highlands. The Median army took part in the final defeat of the Assyrians in northern Mesopotamia (612–605), and when the territory of Assyria was divided between Babylonia and Media, the latter took Assyria proper and northern Mesopotamia, with Harran. War between Media and Lydia (590–585) was ended when these countries accepted the Halys river as their boundary. Cyaxares died shortly afterward. Herodotus' apparent mistake in confusing the solar eclipses of 585 and 610 has cast some doubt on the chronology of Cyaxares' reign. (I. M. D.)

**CYBELE**, the favoured name of an ancient deity, whose worship arose in Asia Minor and spread to Greece and Rome. See **GREAT MOTHER OF THE GODS.**

**CYBERNETICS**, the science of control and communication processes in both animals and machines. The word was introduced and the field popularized by the mathematician Norbert Wiener in a book called *Cybernetics* published in 1948. The field of cybernetics deals with the theory of such systems as the nerve networks in animals, electronic computing machines, servo systems for the automatic control of machinery and other information processing systems. Consequently, it overlaps the fields of neurophysiology, computing machinery, information theory and automation, and seeks to find features common to these diverse disciplines.

In the Industrial Revolution of the 19th century, men's muscles were replaced by the power of steam engines. Men were still required, however, for all important control functions in connection with machines. In the 20th century, machines rapidly took over many of these functions; machines came to control other machines. Instrumental in this trend toward automation has been the expanding technology of electronics and its offspring, high speed automatic computing machinery. While the chemical industry and the telephone system were among the first to be highly automatized, such other industries as automobile manufacturing rapidly followed suit. Cybernetics called attention to this widespread movement and named it the second Industrial Revolution.

These control and communication devices bear the same relation to the steam engines of the first Industrial Revolution that brain bears to muscle. The control systems operate with a low expendi-

ture of energy and their mechanical efficiency is of little importance. Their basic function is not the transformation of energy but rather the processing of information. The inputs of such systems are often the electronic equivalent of sense organs—thermostats, photoelectric cells, microphones or strain gauges. The outputs are the equivalent of an animal's muscles or communicating organs—loud-speakers, electric typewriters or electric motors.

In cybernetics, information is treated as a statistical quantity; a signal is considered to be a particular choice from a statistical ensemble of possible signals. The effectiveness of a control system in processing information must generally be measured by some kind of an average for all the possible signals in the ensemble. See also **AUTOMATION; CONTROL SYSTEMS; INFORMATION THEORY.**

**BIBLIOGRAPHY.**—N. Wiener, *Cybernetics* (1948); *The Human Use of Human Beings* (1950); J. Diebold, *Automation* (1952); W. Ashby, *An Introduction to Cybernetics* (1956). (C. E. S.)

**CYCAD**, any of the palmlike woody plants of the family Cycadaceae, order Cycadales. They are primitive gymnosperms, thought to be evolutionary offshoots from the seed ferns (order Cycadofilicales or Pteridospermae). See **GYMNOSPERMS: Cycadales; PALEOBOTANY.**

**CYCLADES** (mod. Gr. KIKLADHES), 24 islands in the Greek archipelago, around the island of Syros (q.v.) or Syra, the principal town of which, Hermoupolis (Ermoupolis), is the capital of a *nomos* (prefecture). Pop. (1961) 99,959. Area 2,577 sq.km. (995 sq.mi.). The islands are interesting and picturesque; many of them bear traces of the feudal rule of Venetian families.

In antiquity the islands were the centre of a distinctive Bronze Age culture (Cycladic), notable for the production of white marble idols. They flourished again in the 8th to 6th centuries B.C., but later only Delos (q.v.) remained important. It was a great centre of ancient religious, political and commercial life. It was excavated by French archaeologists. Melos (q.v.) was an important ancient source of obsidian. It has Hellenic and Roman remains, and the prehistoric town of Phylakopi was excavated by the British school at Athens. In the volcanic Thera (q.v.) the ancient capital was explored by Baron Hiller von Gärtringen.

Naxos (q.v.), largest and most fertile, contains the highest mountain (Zia, 3,304 ft.) and exports emery. Keos (q.v.), or Zea, and Ios furnish valonia. Kimolos produces fuller's earth. The marble of Paros and Naxos has been practically abandoned; that of Tenos was worked by a British syndicate. Iron ore is exported from Serifos, manganese and sulfur from Melos and pumice for cement (pozzuolana) from Thera. However, the mineral wealth of the Cyclades is, in general, poorly exploited. Though of rugged and barren aspect, the islands export wines, brandy, tobacco and hides. Kythnos (Kithnos), Melos and other islands possess hot medicinal springs. Tenos has a pilgrim church, modern but famous throughout Greece. The islands were occupied by the Germans in 1941 and liberated in 1944. (J. Bo.)

**CYCLADIC CIVILIZATION:** see **AEGEAN CIVILIZATION.**

**CYCLAMEN**, the common and scientific name for a genus of perennial herbs belonging to the family Primulaceae (q.v.), containing 20 species native in the mountains of central Europe and the Mediterranean region. One species, *C. indicum* (or *persicum*), is a well-known florists' plant.

The plants are low-growing herbs with large tuberous roots from the surface of which spring a number of broad, generally heart-shaped or kidney-shaped, long-stalked leaves, which in cultivated forms are often beautifully marbled, ribbed or splashed with white. The flowers are nodding, and white, pink, lilac or crimson in colour. The corolla has a short tube and five large

FROM A. JORDAN, "ICONES AD FLORAM EUROPAE"

**WILD CYCLAMEN (CYCLAMEN EUROPAEUM).** A STEMLess PLANT. SOME TIMES CALLED SOWBREAD BECAUSE ITS CORNS ARE RELISHED BY SWINE

reflexed lobes. After flowering the stalk becomes spirally coiled, drawing the fruit down to the soil.

*C. europaeum* (sowbread) is found as an introduced plant in copses in Kent and Sussex, Eng. A reasonably hardy species for outdoor culture in the U.S., especially in California, is *C. coum* from the eastern Mediterranean region. It is a tuberous-rooted perennial, the roundish leaves of which appear before the spotted, carmine flowers unfold. Related to it, but not quite so hardy, is *C. neapolitanum* from southern Europe, whose fall-blooming flowers are rose coloured or whitish but carmine blotched. Both should be started from tubers. *C. indicum* and its horticultural varieties are the most popular cyclamens as pot plants. Among them are varieties having flowers doubled, crested, shredded or greatly enlarged. All cyclamens prefer cool, moist situations with good drainage.

**CYCLING**, the sport or exercise of riding a bicycle, provides the simplest and most economical means of personal mechanical transport and is widespread throughout the world. Cycle racing, at one time a major sport in the United States, has been represented by several events in each of the modern Olympic games (since 1896) and by events in the British Empire and Commonwealth games and the Pan-American games, and has remained a major sport in Europe and Japan.

This article deals with cycling as a recreation and with touring clubs and racing. For a historical account of the invention and development of the bicycle and for descriptions of various types, see **BICYCLE**.

**Recreation.**—As a pastime, cycling's popularity owes much to its cheapness, but it is also recognized as a beneficial as well as enjoyable light exercise. It is easily mastered by children and adults and is relatively safe. The bicycle is a popular touring vehicle because of its simplicity and lack of noise, and in many countries clubs have been organized with touring in mind. Typical are the Cyclists' Touring club of Great Britain and the Touring Club de France (see *Touring Clubs*, below).

Also involved with cycle touring is the youth hostels movement, since in most countries it is a rule that hostellers must reach the hostel under their own power, which disallows cars and motorcycles.

THE BETTMANN ARCHIVE, INC.

FIG. 1.—EARLY CYCLES: (LEFT) HIGH WHEELER OR ORDINARY, c. 1860; (RIGHT) YANKEE UNICYCLE, PATENTED c. 1870

In Europe provision is often made for cyclists on trunk roads: some countries, like France, build separate cycle tracks and others, like the Netherlands, reserve a portion of the highways.

Following the needs of different countries, many types of cycling and cycles have been developed. Britain, where club life is strong, is known for the lightweight, fully equipped touring roadster. In underdeveloped countries, such as Africa, extremely strong and heavy machines are in demand to carry exceptional loads on unimproved roads, often providing transport for two. On the European continent the prevalence of heavy stone *pavé* led to simple light bicycles equipped with wide low-pressure tires and an internal expanding brake in the rear hub, impervious to weather conditions. A similar machine also became popular in the United States.

Tandem cycling enjoyed a vogue that has had several revivals. Other variations kept some popularity, and tricycles and even

tandem tricycles have adherents in Britain, there being a Tricycle association for those who ride "barrows," as those machines are known.

In all parts of Britain small cycling clubs are found and these are often individualistic—the Vegetarian, the North Road Cycling club for men only, the Rosslyn Ladies, the Buckshee Wheelers for men who served in the forces in the Suez Canal Zone—and they hold social events as well as club runs divided into slow (pot-terers) and fast (hardriders) sections. Most clubs are affiliated to one or more of three bodies, the Cyclists' Touring club, the British Cycling federation or the Road Time Trials council, which between them organize and control cycling for touring or sport in Britain.

Cycling is also used, as it is in the United States, to teach road safety through the co-operation of police and schools in organizing campaigns and competitions to educate children.

After World War II motorized bicycles called mopeds were made in quantity: several millions were made in France and Italy but production was smaller in Britain where, in 1960 for example, only about 80,000 mopeds were made as compared with 2,200,000 bicycles. Often made from standard cycle parts, mopeds generally need pedal assistance to start. Many countries require no licence for those with very small motors, and this makes them popular with utility riders. In Europe the moped in fact largely replaced the bicycle and was used in such large numbers that public transport was affected. (A.L. H. G.)

**Touring Clubs.**—Cycle tours were taken and cycling clubs established almost as soon as the cycle appeared, the Pickwick Bicycle club in London, founded in 1870, being the oldest in the world. The organization of these clubs was chiefly of a social character. To a great extent they were superseded by large organizations. The Cyclists' Touring club (C.T.C.), organized in England in 1878 as the Bicycle Touring club, has members scattered throughout Europe and North America. Many other countries possess national clubs, as for instance the League of American Wheelmen, organized in 1880, and the Touring Club de France, founded in 1895, of whose objects cycling is only one, though the chief.

The aim of these national associations, which form an international touring league, is the promotion of cycle touring. To this end they publish roadbooks, maps and journals. They recommend hotels, with fixed rates, in their own and other countries. They appoint representatives to aid their members when touring, and they succeeded in inducing most governments to allow members to travel freely across frontiers without paying duty on their machines. In all countries they have erected warning signs at dangerous places.

Another important part of the work of these clubs, both directly and indirectly, was the improvement of roads. In Belgium, for instance, the cycle worked a veritable revolution in the national life. The paved roads, before the advent of the bicycle, were so bad as to be impossible for even light traffic. A cycle tax was introduced and devoted at first to the construction of paths on which cyclists have equal rights with pedestrians, and next to the replacement of the old paving by macadam.

There are a great many touring cyclists in the United States, riders who are not interested in speed but concentrate upon piling up mileage in a calendar year. These enthusiasts are associated with colleges, clubs and youth hostels. Some of the country's most active touring groups are the New York Cycle club, the Western Wanderers of San Francisco and the Long Island Wheelmen's association. The L.I.W.A. has a long history of conducting centuries, as 100-mi. runs are called. These are a remnant of the era before the automobile arrived upon the scene, when mixed groups pedaled along leisurely and enjoyed the beauty of the countryside. The members of the touring groups write and tell of their experiences, and many are camera enthusiasts who give lectures with the aid of colour slides and motion pictures taken on their rides.

The automobile parking problem has resulted in a revival of bicycle riding at many college and university campuses. The University of Southern California student council suggested that

students use bicycles; four out of five girls at Smith college ride bicycles; there have been as many as 4,000 bicycles at one time on the University of Michigan campus; and a large proportion of students at Yale, Harvard, Vassar and Dartmouth use bicycles. The University of Indiana raises funds for scholarships by attracting as many as 25,000 spectators to its annual "Little 500," which it calls its 50-mi. bicycle race held in the stadium at Bloomington, Ind.

According to statistics compiled by the bicycle manufacturers of the United States, 27,000,000 Americans ride bicycles. Many are members of the C.T.C., which publishes logs of persons who ride more than 10,000 mi. a year. (W. RA.)

**Racing.**—The man who made the first rideable bicycle, Kirkpatrick Macmillan, undertook the first race. He had cycled from Thornhill, Dumfriesshire, Scot., to Glasgow in 1842, and after a sensational appearance in court for knocking down a child he set off for home again. He met his friend the coachman of the Glasgow-Carlisle mail coach and wagered him that he would reach Sanquhar on his machine before the coach did. This was taken up by the driver and the race was on. It was neck and neck for many miles but Macmillan had the advantage of not having to stop at the halting places for the mail and passengers. At Old Cumnock the coach was well behind and the cyclist easily reached Sanquhar a well-established winner. But Macmillan's crude steed of wood with swinging treadles, rods and cranks on the back hub was forgotten before it had established itself as a machine for personal propulsion.

The bicycle was reinvented even more crudely in Paris in the 1860s when Pierre and Ernest Michaux put cranks on to the hub of the front wheel and started the real cycling era with the *vélodépède* or, as it was called in Britain, the boneshaker. On May 31, 1868, Napoleon III offered a gold medal for a cycle race and James Moore, an Englishman then resident in Paris, won. The date is interesting as it is the day before the first boneshaker race was staged in England: on Whit Monday, June 1, there was a cycle race near the "Welsh Harp," Hendon, Middlesex.

There followed many such racing events. The racing cycle needs a bigger gear to move fast and, as the gear of the boneshaker was the diameter of its driven wheel, the makers increased the size of the front wheel until it would just go under the crotch of the rider. Slender metal wheels with wire spokes replaced the cart-wheel design and the gracious high "ordinary" was evolved. Some of the most famous men of the early racing days were efficient pedalers on the ordinary, and the chief use of the big wheel was as a racing machine. British high-wheel developments were quickly copied in Europe, especially in Germany and Bohemia, and the largest modern cycle-making firm in the U.S. was founded as an ordinary manufacturer in Germany.

Championship races on the high bicycle were established in 1878 when the National Cyclists' union, originally the Bicycle union, was founded and the universities of Cambridge and Oxford recognized the new sport. The ordinary championships continued until 1892 after the safety machine had been introduced in 1885. In 1882 H. L. Cortis won all four titles, 1, 5, 25 and 50 mi., and in that year on an ordinary he was the first man to ride over 20 mi. in an hour on the same type of machine. Title racing in the U.S. commenced in 1883 when G. M. Hendrie won a challenge road race from W. G. Rowe and was declared the first cycling champion. A great ordinary performer in Britain was G. Lacy Hillier, who became one of the earliest cycling journalists. He opposed the pneumatic tire and the transition of the ordinary to the safety (and invented the word "aeroplane," prophesying that flying, when it came, would reach 200 m.p.h.). There were also Maj. C. E. Liles; H. Synner, who practised secretly to start his sprint from an earlier starting point than he had been known to use, and on the big race day brought out his surprise tactics; R. J. Mccredy from Ireland; and the most famous pedaler of them all, J. H. ("Johnny") Adams.

From the U.S. came the phenomenal A. A. Zimmerman, who pedaled as small a gear as was currently possible on the high bicycle and won by his unbelievable ability to get the pedals round at speed. In 1899 there was a sensation in America when Charles

THE BETTMANN ARCHIVE, INC.

FIG. 2.—CHARLES M. ("MILE A MINUTE") MURPHY DURING THE RACE IN WHICH HE RODE FOR A MILE BEHIND A LONG ISLAND RAILROAD TRAIN IN 57½ SEC.; JUNE 30, 1899

M. ("Mile-a-Minute") Murphy rode on a wooden track between the rails behind a train with a wind shield at the back. At the first attempt to cover a mile within a minute, the engine could not reach the required speed. On the actual record ride behind a larger engine its weight rocked the track and nearly brought Murphy to disaster. He was shaken out of his shelter and got back only with great difficulty. At the end of the mile, which he covered in 57½ sec., the engine driver shut off steam too soon and the helpers on the rear of the pullman caught Murphy as he ran into the train and hauled him aboard.

In response to the growing interest in racing in the 1880s and '90s, organizations for the government of the sport were established in many countries. Among the most important, in addition to the National Cyclists' union in England, were the National Cycling association (N.C.A.) in the U.S. (the Amateur Bicycle League (A.B.L.) of America was not founded until 1921), The Canadian Wheelmen's association in Canada and the Union Vélocipédique in France.

The British National Cyclists' union founded an international organization for world racing and championships, but England, Scotland, Ireland and Wales were given separate representation and Britain dominated the international scene and British riders were supreme on road and track. Other countries resented this situation and in 1900 France, Belgium, Italy, Switzerland and the United States founded the Union Cycliste Internationale (U.C.I.) without Britain, which country had later to apply for membership with a single representation. In the 1890s Britain had won 6 of the 17 international title races and the U.S. provided four of the winners, but Britain did not win again for another eight years.

France, the country to which the founding of the U.C.I. was chiefly due, in 1903 established the Tour de France, covering about 3,000 mi. in approximately 25 days. Other European countries followed suit with similar "tours." In 1893 the founder of the Tour de France, Henri Desgrange, had established an unpaced hour record with 21 mi. 1,614 yd.; this blue ribbon classic record was improved by French, Belgian, U.S., Swiss, German, Italian and Dutch riders until, by 1960, Roger Rivière of France held the record with 29 mi. 739 yd.

The road race has been divided into two major styles. In Britain the main class of racing is the time trial wherein the riders start individually and are timed home again, so that the rider with the shortest elapsed time is the winner. This style was evolved after the 1890s, when the police prohibited racing in line. Elsewhere the massed-start road race is the most popular, and the first over the line at the finish is the winner. The Tour de France is run in that fashion with an occasional time trial section and the daily times of the riders are aggregated. At mid-20th century the race in line came into vogue again in Britain, but legal regulations were issued in 1960 to control the timing and

location of such events because of the growing weight of motor traffic. The time trial, although included in the regulations, was left to continue generally in its own way. (H. H. EN.)

By 1900 bicycle racing had become a major sport in the United States and Canada. A troupe of English professionals inaugurated it in the U.S. about 1870 when they introduced the high wheel. The dirt tracks used for trotting races served for the first set of cycling events, staged near Springfield, Mass. With the widespread adoption of the safety bicycle about 1889, board tracks were introduced.

For a time cycling was extremely popular all over the country. Manufacturers of bicycles and accessories kept the sport alive by organizing competing racing teams. With the coming of the automobile about 1895 cycling as a utility began to die out, only to return later as a sport, especially where tracks were located.

The first six-day bicycle race at Madison Square Garden in New York city was held in 1891, and this branch of cycling for many years attracted people by the thousands to the Garden and to the Coliseum in Chicago. In 1927 Detroit, with the completion of its new Olympia, holding 17,000 persons, saw its first six-day race, and that city joined the six-day circuit. In New York city six-day racing was witnessed by sports enthusiasts twice a year, in December and March, while Chicago had its two races in October and February. Six-day racing in North America spread from New York to San Francisco and Los Angeles, from New Orleans to Toronto (in 1912) and Montreal (in 1929).

Almost as rapidly as the sport had grown, however, the interest waned, and by 1938 the average weekly attendance at the New York races had dropped from more than 100,000 to about 50,000. As a result Madison Square Garden dropped six-day racing from its sports calendar, and other cities followed.

New records continued to be made. In 1940 Raymond Bryan rode from New York city to San Francisco, a distance of 3,149 mi., in 27 days 11 hr. In 1941 Alf Letourner, a professional rider, traveled at the rate of 108.92 m.p.h. behind a midget auto racing car on a California state highway. Letourner was officially timed by an American Automobile association representative.

In the United States the N.C.A. controls professional racing. This body succeeded the League of American Wheelmen. All six-day races are held under N.C.A. sanction.

Since World War II bicycle racing in the United States has been confined almost exclusively to amateur riders, who compete under the sanction of the A.B.L. of America. With the disappearance of the banked, outdoor board tracks used by the professionals, the amateurs were forced to compete on the highways, in the early morning hours, or occasionally through town streets, and also on automobile race tracks and trotting horse tracks. Rarely is admission charged for any of these contests. The only professional racing has been a sporadic six-day race.

The A.B.L.'s program is financed by the American bicycle industry. The A.B.L. conducts state and national championships annually, but less than half of the states have an organized program. There are 15 to 20 states represented in the annual national title events, and the greatest concentration of activity may be found in New York, New Jersey, California, Michigan, Wisconsin, Massachusetts, Connecticut, Maryland, Illinois, Missouri, Pennsylvania and Washington. The many divisions in the national championships are: senior men, women, junior men (under 17), junior girls (under 17), boys and girls (over 15), boys and girls (over 10), midgets (9 to 10) and cubs (7 to 8).

The outstanding United States amateur road races are the Tour of Somerville (N.J.), the Grand Prix of Long Island, the Connecticut Valley championship and the Eastern Seaboard championship. United States amateurs also compete regularly in the two big Canadian races, the Tour du St. Laurent at 794 mi., and the 170-mi. Quebec to Montreal race. These races, and the Tour of Mexico, are rated the major road racing events in the western hemisphere.

Yale University's bicycle club revived intercollegiate bicycle racing in 1960. However, bike racing at the colleges is recognized only as a club sport by the institutions and intercollegiate athletic associations.

As for professional racing, the U.C.I. has more than 70 nations in its membership. The United States is the only country represented by two groups, the N.C.A. (professional) and the A.B.L. (amateur). The A.B.L. was admitted to membership in 1941 when it severed relations with the professionals. Among the members admitted in 1960 were the Republic of Korea, Mongolia, Kenya, Cameroon, the Philippines and Malaya. World professional and amateur championships have been enlarged to include three titles for women.

Parimutuel betting on bicycle racing is permitted in Japan, Denmark and Central America, and the races attract great crowds as a result of the wagering, but millions still attend the sport in Europe, Asia, South America and Australia every year. Six-day racing continues to draw heavily in Milan, Berlin, Dortmund, Frankfurt, Cologne, Zürich, Antwerp, Copenhagen, Aarhus, Brussels and Münster.

The Tour of Egypt and the Tour of Tunisia, for professionals, attract the world's biggest racing names and are considered rival events to the more ancient Tour de France and Giro d'Italia, also for professionals. The Tour de France, started officially in 1903, still remains perhaps the most important road event of the sport. Cycling events have been included in the modern Olympics since the first games in 1896 (see OLYMPIC GAMES). (W. RA.)

**CYCLONE.** A name variously applied to rotating wind systems of a stormy character. In meteorology the term is applied to an area of relatively low pressure, usually 50 to 1,000 mi. in diameter, together with its revolving wind circulation; in common meteorological parlance these often are referred to as "lows." In popular usage the name cyclone sometimes is given to the small, extremely violent, twisting cloud appendage which is more properly called a tornado (*q.v.*). Meteorologists classify cyclones as (1) tropical cyclones and (2) extratropical cyclones. The first are called typhoons in the far east and hurricanes or cyclones elsewhere. For a complete discussion of them, see TROPICAL STORM. The second type, the extratropical cyclone, is the common rain- and snow-producing disturbance of middle and high latitudes. In England this type is commonly called a depression.

Both types of cyclones have a counterclockwise wind circulation in the northern hemisphere and a clockwise rotation in the southern hemisphere. The areas of low pressure appear on weather charts as oblong or nearly circular systems of isobars which stand out in sharp contrast with the areas of high pressure or anticyclones (*q.v.*).

The extratropical cyclones generally move from west to east with the prevailing winds of their latitude, producing large areas of precipitation and relatively strong winds. The approach of an extratropical cyclone is recognized by an increase in the wind and a change in its direction from southwest through southeast to northeast, accompanied by falling pressure, increasing cloudiness and precipitation. As the centre moves eastward away from the observer, the pressure rises and the wind comes in from a direction between southwest and north. In most cases the weather then improves, although rain and snow of the shower type and general cloudiness may prevail. Warm air usually precedes the cyclone and cold air moves in somewhat suddenly behind. There is a typical pattern of these warm and cold air currents having distinct boundaries between them, known as fronts. It is in these contrasting temperatures that an extratropical cyclone is most clearly differentiated from a tropical cyclone, which contains horizontally homogeneous air.

On climatic charts as well as on most weather maps relatively permanent cyclonic centres are found in the northern Atlantic and Pacific oceans, known respectively as the Icelandic and Aleutian lows. In summer, semipermanent low-pressure centres exist over warm continental regions. They are in some places belts of low pressure, such as that which extends from the Sahara desert through the Red sea and Asia Minor to the Persian gulf, northern

India and Burma. A belt of low pressure also is found near the equator between the circulations of the oceanic anticyclones of the northern and southern hemispheres.

See METEOROLOGY; WIND; see also references under "Cyclone" in the Index-volume. (H. R. B.)

**CYCLONITE** (cyclotrimethylenetrinitramine,  $C_3H_6O_6N_6$ , RDX, hexogen,  $T_4$ ) is one of the most powerful explosives known. It was discovered by Hans Henning in 1899 but was not used prior to World War II. During that war most of the major warring nations introduced it into military use, but it was manufactured on a large scale only in the U.S. Its structural formula is:

The manufacture by the conventional process involves the nitration of hexamethylenetetramine,  $C_6H_{12}N_4$ , by a large excess of 98% nitric acid, during the course of which a considerable fraction of hexamethylenetetramine is oxidized. A secret manufacturing process which was developed in the U.S. and Canada and used in large-scale production during World War II made cyclonite into a rather inexpensive explosive available in large quantities to the Allies.

Cyclonite is a white, hard, crystalline substance, melting at  $204^\circ\text{C}$ . (with decomposition); specific gravity 1.82. It is insoluble in water and only slightly soluble in some other solvents.

Cyclonite is relatively sensitive to percussion and is used therefore largely in mixtures with other substances, such as TNT and beeswax, to decrease its sensitivity. These mixtures are known as Compositions A, B and C in the United States. Composition A is a semiplastic explosive which is pressed; Composition B is poured in molten form in the loading of ammunition. Composition C is a plastic explosive resembling putty which is used mainly for demolition purposes.

The name RDX was coined by the British as a contraction of "Research Department Explosive" and gained acceptance in the United States. The term hexogen was used by the Germans and the term  $T_4$  by the Italians.

See W. A. Noyes, Jr. (ed.), *Chemistry*, vol. vi of *Science in World War II* (1948); T. L. Davis, *The Chemistry of Powder and Explosives* (G. B. K.; R. O. Be.) (1941-43).

**CYCLOPEAN MASONRY**, a term in architecture, used to define the rude polygonal masonry employed by the early Greeks, the Etruscans in Italy, in Tiahuanaco in Peru, etc. (from the Cyclopes, the supposed builders of the walls of Mycenae).

In the earliest examples it consists only of huge masses of rock of irregular shape piled one on the other and depending on their great size and weight for cohesion; sometimes smaller pieces of rock filled up the interstices. The walls of Tiryns, Mycenae and early Athens were so constructed. Near the gates the blocks were well squared to fit one another.

The date cannot be determined by the type of construction; where stratified rocks were obtainable, horizontal coursing may in some cases have been adopted early; in fact, there are instances in Greece of a later wall of cyclopean construction being built over one with horizontal courses.

**CYCLOPS** ("Round-eye"), a word having several uses in Greek legend and history. In Homer the Cyclopes are one-eyed cannibal giants, living a rude pastoral life in a distant land (traditionally identified with Sicily), having no social unit larger than the family (see ACIS; POLYPHEMUS). In Hesiod they are sons of Heaven and Earth, three in number—Arges, Brontes and Steropes (Bright, Thunderous, Lightener)—who forge the thunderbolts of Zeus; later authors say Apollo killed them for making the thunderbolt which slew Asclepius, and make them the workmen of Hephaestus.

The walls of several ancient cities (e.g., Tiryns) of Mycenaean architecture are sometimes said to have been built by Cyclopes, perhaps the same as those of Hesiod. Hence in modern archaeol-

ogy the term cyclopean is applied to walling of which the stones are not squared.

See W. Roscher, *Lexikon* (1924); *Larousse Encyclopedia of Mythology*, p. 141 (1959).

**CYCLORAMA**: see PANORAMA.

**CYCLOSTOME**, any of the lampreys and hagfishes, round-mouthed, eel-shaped, jawless fishes that compose the class (or order) Cyclostomata (Marsipobranchii or Cyclostomi). Together with fossil ostracoderms (q.v.; armoured, jawless fishes), these primitive vertebrates are often grouped in a superclass (or class) Agnatha.

Cyclostomes are all aquatic creatures, smooth, slimy and scaleless, with a cartilaginous skeleton. The known species—about 50—inhabit the waters of the temperate zones. Most are marine, but a few lampreys are confined to lakes and streams, and the sea lampreys spawn in fresh waters. The maximum size ranges from less than six inches to about three feet.

**Importance.**—Most of the cyclostomes are regarded as harmful to man because they destroy food and game fishes. The larger lampreys attach themselves to fishes and drain their blood. In the Great Lakes vast damage is thus inflicted by the sea lamprey, *Petromyzon marinus* (fig. 1[A]), which entered these waters by way of a canal and soon became very abundant, feeding extensively on lake trout and spawning in the lake tributaries. Efforts are made to control the increase of these lampreys by destroying the mature adults, which are caught in a weir placed in the spawning stream, and by the use of chemicals to destroy the larvae.

(A) AFTER DEAN; (B) BY COURTESY OF CARL L. HUBBS  
FIG. 1.—TWO PRINCIPAL TYPES OF CYCLOSTOMES: (A) SEA LAMPREY (*PETROMYZON MARINUS*); (B) PACIFIC HAGFISH (*EPTATRETUS STOUTII*)

Marine food fishes are bled by seagoing lampreys, but suffer greater damage from the attacks of the hagfishes (fig. 1[B]), which eat their way into and through the flesh of food fishes. Large numbers of valuable fish are thus destroyed. Fish that are caught in nets or on set lines are particularly subject to such loss. On the other hand lampreys are esteemed as food in many places, and their larvae are extensively used as bait by fresh-water anglers. Adult brook lampreys, which are harmless because they do not feed, furnish, along with the larvae of all lampreys, considerable natural food for trout and other game fishes.

Scientifically the cyclostomes are of great significance, because they are the most primitive of the living vertebrates. The lamprey larva or ammocoete in particular is regarded as providing the closest facsimile of the ancestor of the backboneed animals. For this reason the ammocoete is recommended as one of the types to be studied in comparative anatomy courses. Adult lampreys and the hagfishes depart from the ancestral form since many of them are specialized for parasitic existence.

**Distinctive Characters.**—The cyclostomes differ from all other living vertebrates in many important respects. None of their gill arches have been converted into jaws, for which reason they are classified among the jawless vertebrates, or Agnatha (a group that contrasts with the jaw-bearing vertebrates or Gnathostomata). The cyclostomes are also devoid of any trace of the paired fins (pectorals and pelvics), which, except for occasional loss through degeneration, are present in all other fishes and, in the form of limbs, are represented in all higher vertebrates. The muscular, protrusible tongue in all cyclostome fishes, and in the adult lampreys the buccal disc or funnel (fig. 2) as well, bear teeth that are composed of thin horny tissue rather than dentine or enamel. Instead of forming partitions between slits, the gills lie in spherical pouches that connect with the pharynx and with the exterior through tubes. The internal ear has only one or two

(A) BY COURTESY OF CARL L. HUBBS. (B) FROM D. S. JORDAN, "FISHES"

semicircular canals, not three as in typical vertebrates (the horizontal canal is missing). The brain is small, primitive and distinctive, and the brain case is incomplete, especially in the hagfishes. The skeleton is wholly cartilaginous, without any trace of calcification. The notochord is persistent throughout life and is nowhere constricted. No vertebrae proper (centra) are formed. The olfactory organ is a single median sac with an internal opening into the cavity of the pituitary and an external opening that lies on the midline either on the top or at the front of the head. On the basis of the narial structure some authorities classify the cyclostomes, along with certain extinct groups discussed below, as the Monorhini. All other vertebrates are said to be diplorhine, for they have paired nostrils, with one sac on each side of the head.

**Life History.**—All lampreys spawn in the spring on gravel beds in streams. The marine species migrate into the streams to breed, passing over dams and other obstructions. They inch their way up the sheer vertical walls by adhering by their sucking mouth disc. A lamprey life cycle is shown in fig. 3.

The males arrive first on the spawning grounds and start to prepare the nest. By adhering to and tugging out pebbles, the lamprey fashions a shallow depression. The newly arrived female then maintains a hold on a stone while the male clamps onto the female and twists around her, fertilizing the eggs as she extrudes

FIG. 3.—LIFE CYCLE OF THE SEA LAMPREY (*PETROMYZON MARINUS*) IN THE GREAT LAKES. THE LIFE SPAN OF THE LAMPREY MAY BE AS LONG AS 8½ TO 7½ YEARS, MOST OF THIS TIME SPENT IN THE SEDENTARY LARVAL STAGE; THE ADULT LAMPREY DIES SOON AFTER SPAWNING

them. The parents then loosen the pebbles lying on the rim of the nest so that the particles fall into the depression, thus surrounding and covering the eggs. By the time the spawning act is completed the adults are emaciated, and in a short time they die.

After about two weeks the eggs hatch and the larval or ammocoete life begins. The several size groups, each resulting from one year's spawning, indicate that the larval stage lasts several years. The wormlike, toothless, nearly blind larvae live in burrows in the bottom of mixed sand and mud, coming out at night to feed on the organic ooze, which is strained through the thick cirri in the hoodlike mouth.

After at least three years (often more) of such life the ammocoete rapidly transforms in the late summer and fall into the adult form. Many changes take place simultaneously: the eye becomes much larger and better developed; the hood is replaced by the disc and the cirri by teeth; the nostril opening moves from the front to the top of the head; and the body becomes rounder in cross section, the flesh firmer and the colour brighter. During this transformation, or metamorphosis, the lamprey shrinks considerably in length.

Soon after metamorphosis the sea lampreys become silvery and

large-eyed in preparation for life in the ocean, to which they promptly migrate. Some of the nonparasitic brook lampreys pass through this same stage, known as the macrophthalmia, as though in racial remembrance of the former seaward journey, though this trip has been abandoned for millenniums.

All parasitic lampreys feed and grow rapidly on their nutritious diet of fish blood. Those that remain in fresh water live thus for a year or more. A larger size is reached in the sea, presumably because of faster growth rather than a longer life span. After they become sexually mature, the parasitic species spawn once and then die, to complete the life cycle.

The nonparasitic species metamorphose at a size at least as large as do their parasitic relatives, but the teeth are poorly developed and the gut shrinks to a solid strand. Without taking any food they complete, overwinter, the ripening of the sex cells that had begun before the metamorphosis. Like the parasitic species they then spawn and die.

The hagfishes deposit a large, yellowish, yolk-filled egg. This is enclosed in a protective horny shell and is attached to the bottom of the sea by threadlike tendrils. The development is slower than in lampreys, and the young are much larger when hatched. They look very much like the adults, into which they gradually develop without a metamorphosis. In life history as well as in structure the hagfishes are very much unlike the lampreys.

**Evolutionary History.**—The fossil record as well as the evidence from comparative anatomy indicates that the Cyclostomata are cousins of the earliest and lowest vertebrates. The oldest fossilized remains of vertebrate animals, found in the Silurian deposits with traces in the yet more ancient Ordovician rocks, prove on close study to be similar in many respects to lampreys

and hagfishes. Superficially the fossils (fig. 4) bear little resemblance to their modern relatives, which, in correlation with their parasitic habits, are highly specialized in some respects and in other ways much degenerated. In fundamental anatomy, however, they were much alike. Thus the extinct forms resembled the cyclostomes in lacking jaws, for the anterior gill arches remain unaltered. They appear also to have lacked true paired fins, though in some species flipperlike flaps were developed in place of pectoral fins. The extinct forms agreed further with the cyclostomes in gill structure and in having had only two semicircular canals in the internal ear. Most of the extinct groups had, like the cyclostomes, a single median nostril.

Most of these early fishes, and naturally those that are best known because most thoroughly preserved, were heavily armoured with dermal bone—hence the group name Ostracodermi that has often been applied to them as a whole. On these grounds many paleontologists have regarded the bizarre armoured fishes as the direct ancestors of the more ordinary modern types. It is more logical to assume, however, that both the armoured and the progressive types were derived from unarmoured fishes with the usual fish form. The highly specialized mailed kinds were probably evolved to provide protection from such enemies as the gigantic "water scorpions" of early times. Furthermore, such types had a much greater chance than their slender, soft-bodied and probably free-swimming ancestors to be fossilized and well preserved in the rocks. The more highly evolved, heavily armoured types persisted throughout Late Silurian time and all of the Devonian, along with the earlier jawed or gnathostome fishes which are classified as the Placodermi. None of the Ostracodermi is known to have survived beyond the end of the Devonian, but some primitive member of the Agnatha must have persisted, to give rise to the living group with which we are dealing. In conformity with an evolutionary rule, the highly specialized group died out while some generalized relative lived on.

**Fossil Relatives.**—Since the cyclostomes are the only living Agnatha or jawless vertebrates, their relatives are to be sought exclusively among the extinct fishes. Three groups, commonly treated as orders, all Paleozoic and none persisting beyond the Devonian, show evidence of relationship with the lampreys and hagfishes: they are the Osteostraci, Anaspidia and Heterostraci, composing the Ostracodermi. The common feature of all ostracoderms is their plated or armoured skin (*see* OSTRACODERM).

In some ways the most lampreylike of the fossils were the Anaspidia (fig. 4[A]). These Silurian and Devonian creatures seem primitive because of their small size (none exceeding ten inches), their almost ordinary fish form and their small scales, which apparently overlaid the muscle segments.

As in the cyclostomes, they had the eyes lateral and a single nostril in front of the third or pineal eye (fig. 5), and the gill openings formed a row of pores on each side.

The Osteostraci (fig. 4[B]) also had a median, superior nostril and a row of porelike gill openings, but differed from the Anaspidia (and from the cyclostomes) in having the head enclosed in a flat bony shield.

The Heterostraci were armoured fishes (fig. 4[C]) that closely resembled the Osteostraci. Both groups were abundant in Late Silurian and Early Devonian times and disappeared completely by the end of the Devonian. In this group the armour lacked the bone cells that were characteristic of the Osteostraci. The paired eyes were far apart, and there was no dorsal nostril. The olfactory organs, which were close together but paired, are supposed to have opened into the mouth cavity.

The Devonian group known as Cycloidae or Palaeospondyloidea is

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

FIG. 6.—FOSSIL REMAINS OF PALAEOSPONDYLUS GUNNI FROM THE SILURIAN OF SCOTLAND (TWICE NATURAL SIZE)

recognized for one of the most problematical of the fossil vertebrates, *Palaeospondylus* (fig. 6), which by some has been thought to be an ancient lamprey or lampreylike animal. If so, the living lampreys must be very degenerate, for they lack the vertebral centra that are well developed in the fossil. Other zoologists have regarded it as a larval arthrodire. The remains of this one- to two-inch fishlet abound in one quarry in Scotland and have been very thoroughly studied. Nevertheless, opinions differ as to whether or not the group had gills or paired fins, and relationships of the group remain uncertain.

### CLASSIFICATION

The Cyclostomata are divided into two subgroups, which are different in anatomy, appearance and habits:

	<i>Hyperoartii</i> (lampreys)*	<i>Hyperotreti</i> (hagfishes)
Nasal opening	On top of head	At front of head
Pituitary canal	Closed internally	Opening into pharynx
Cartilaginous rings around this canal	Lacking	Developed
Pineal eyes	Easily visible	Degenerate
Eyes	Well developed	Vestigial
Oral funnel	Developed	Not present
Teeth	On disc also	Only on tongue
Tentacles about mouth and nostril	Lacking	Six, supported by cartilage
Number of gills	Always 7	5 to 14
Gill openings	Close to head	Remote from head
Internal gill tubes	United	Separate
Duct on left side, pharynx to exterior	Lacking	Developed
Branchial skeleton	A conspicuous basketwork	Greatly reduced
Dorsal fin	One or two well developed	None or only a trace
Neural arches	Present	Lacking
Dorsal and ventral roots of spinal nerves	Distinct	United
Kidneys	Compact organ	Separate
Eggs	Minute, without horny shell	Very large, with horny shell
Development	With larva and metamorphosis	Direct (young much like adult)
Spawning place	Gravel in streams	Ocean floor
Feeding on	Fish blood	Fish flesh, etc.
Type of parasitism	External	Internal

\*The characters are those of adult lampreys. In several respects the lamprey larvae agree with the Hyperotreti.

The differences between the lampreys and the hagfishes are so extensive and so fundamental as to lead some authorities to think that the two groups are unrelated. They appear, however, to have had a remote common ancestor.

**Lampreys.**—The Hyperoartii, or lampreys, may be classified into three families. The chief family, Petromyzonidae, comprises all the northern hemisphere species. The well-known sea lamprey, *Petromyzon marinus*, occurs on both sides of the Atlantic. Three related genera, *Eudontomyzon*, *Entosphenus* and *Lampetra*, occur in Eurasia as well as in North America. The primitive genus *Ichthyomyzon*, with more species than any other, inhabits only the fresh waters of eastern North America. *Caspiomyzon* is confined to the Caspian sea basin. About half the species of Petromyzoni-

FIG. 5.—HEAD OF LIVING LAMPREY COMPARED WITH A FOSSIL RELATIVE: (A) SEA LAMPREY (PETROMYZON); (B) SILURIAN ANASPIDIA (RHYNCHOLEPIS)

dae are of the dwarfed, nonparasitic brook type, with weak teeth. Nearly all of these have arisen through degeneration from different parasitic kinds, and hence they are named as distinct species (in the genera *Ichthyomyzon*, *Eudontomyzon*, *Entosphenus* and *Lampetra*).

The distinctive lampreys of the southern hemisphere are placed in two families, Geotriidae and Mordaciidae, each with a single genus (*Geotria* and *Mordacia*). These southern genera live along the coasts of Chile, New Zealand and Australia. Like all other lampreys they spawn in fresh water. (See also LAMPREY.)

**Hagfishes.**—All the Hyperotreti, or hagfishes, are marine. Except for a few species in deep water within the tropics, all are inhabitants of the temperate zones—in the North Atlantic, western North America, Japan, New Zealand, Chile, Patagonia and South Africa. Fewer than 24 species are recognized. They are generally regarded as constituting a single family Myxiniidae. Some authorities restrict Myxiniidae to genera (principally the genus *Myxine*) that have a single external gill opening on each side, placing the genera (*Eptatretus*, etc.) with 6 to 14 such openings on each side in a separate family, Eptatretidae. In view of the similar basic structure of all hagfishes, and the closely approximated gill openings of the genus *Paramyxine*, the family separation has generally been abandoned. See also HAGFISH.

**CYCLOTRON.** The cyclotron is a device for accelerating nuclear particles to very high speeds. These high-speed particles are used by physicists to investigate the properties of atomic nuclei and to produce nuclear transmutation and artificial radioactive substances. See ACCELERATORS, PARTICLE; see also references under "Cyclotron" in the Index volume.

**CYGNUS** (the Swan), in astronomy, a constellation of the northern hemisphere fabled by the Greeks to be the swan in the form of which Zeus seduced Leda. Its brightest star is Deneb, a first magnitude star.  $\beta$  Cygni is a fine-coloured double star, consisting of a yellow star, third magnitude, and a blue star of magnitude 5.5. A cross formed by six stars of the constellation is called the Northern Cross.

A wide double star, 61 Cygni, because of its large proper motion of 5" per annum, was singled out by F. W. Bessel for the first successful attempt to measure stellar parallax. The parallax is about 0.31". The constellation includes one of the most interesting regions of the Milky Way for astronomical research.

**CYLINDER.** In its oldest mathematical sense a cylinder is the space swept out by a rectangle (fig. 1) rotating around one side as axis. It is from the Greek *kylindros*, "roller," from *kylindein*, "to roll." The side (called the *generatrix*,  $g$ ) parallel to the axis ( $a$ ) traces the curved *cylindrical surface*; the other two sides (each equal to  $r$ ) trace the circular *bases* of such a cylinder, which is more precisely termed a *right circular cylinder*. The most common generalization supposes  $g$  not perpendicular

FIG. 1.—RIGHT CIRCULAR CYLINDER

to the parallel base-planes, but oblique, inclined at a fixed angle (like a pencil in writing), and tracing in the planes equal circles about the ends of the oblique axis as centres (fig. 2).

**Area and Volume.**—The perpendicular distance between the planes is called the cylinder's *altitude* ( $h$ ). The area of each base is clearly  $\pi r^2$ ; the product of base and altitude is the cylinder's volume  $\pi r^2 h$ ; the area of its curved surface is the product of its altitude and the circumference of its base; i.e.,  $2\pi r h$ . A sector of the cylinder has a volume and curved surface proportional to the sector's angle.

**Archimedes' Work.**—The metrical relations of a cone, hemisphere and cylinder of the same base and height were studied by Archimedes of Syracuse (c. 225 B.C.), who showed (in Book I of his *On the Sphere and Cylinder*) their volumes to be respectively as 1:2:3; and the surface of the hemisphere to equal the curved surface of the (right) circumscribing cylinder. These relations were deemed so important and beautiful by Archimedes that he expressed the wish that the sphere-cylinder figure be engraved on his tomb, a wish fulfilled by command of Marcellus and furnishing a mark by which the quaestor Cicero identified it in 75 B.C., after nearly a century and a half.

FIG. 2.—OBLIQUE CYLINDER

**Generalization of Concept.**—The more modern view regards the cylindrical surface as the cylinder itself (compare the cone, *q.v.*), and defines it in full generality as the surface traced by a right line ( $g$ ) moving without turning; i.e., always parallel to itself or to some fixed line or direction. To make such a surface definite, a *directrix* ( $D$ ), generally a curve which the generatrix ( $g$ ) describes upon passing through its points (fig. 3), must be prescribed. Obviously such a surface is *developable*; that is, it may be imagined as flattened or rolled out smooth, without stretching, tearing or crinkling, on a tangent plane which evidently touches the surface full length along an element in any one of its positions. In case the directrix is an ellipse, the surface has been called a "cylindroid," and may be defined as the path of an ellipse moving always parallel to itself, its centre always on a fixed line or axis. The same name is also applied to the conoidal cubic surface traced by the intersection of two moving planes  $y = x \tan \theta$ ,  $z = m \sin 2\theta$  whence, on eliminating the parameter  $\theta$ , there results the equation of the surface,  $z(x^2 + y^2) = 2mxy$ . Clearly, any cylindrical surface may be viewed as a straight tube traced

FIG. 3.—GENERATRIX AND DIRECTRIX

by a directrix moving always straight and keeping always parallel to itself.

**Sections.**—If a directrix has a centre, the line through it, along which the centre moves parallel to  $g$ , is called the *axis*. Any plane through the axis makes a *principal section*, namely, two opposite parallels, elements of the surface, which, with two parallel sections of this plane by two parallel planes through the cylinder, form a parallelogram. This parallelogram becomes a rectangle if the two planes are perpendicular to the generatrix  $g$ . In a right circular cylinder such a perpendicular plane cuts the cylinder in a circle, but any plane oblique to the axis cuts the cylinder

in an ellipse, which is thus seen to be the parallel projection of a circle on an inclined plane, a fact leading directly to many properties of that curve (see ELLIPSE). If the circular cylinder is not right but oblique, then the plane sections across it are in general elliptic, but become circular for planes parallel to the directrix circle. The same conditions occur in oblique cones.

The cylinder may be regarded as a cone whose vertex has withdrawn to infinity (G. Desargues, 1639). Accordingly, all oblique sections of the right circular cylinder yield ellipses, but those parallel to an element ( $g$ ) or the axis yield a pair of parallels, a limiting case of the parabola. Still further turned, the plane again cuts through, giving ellipses. But the same two parallels may

be considered to be a limiting case of the hyperbola  $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ , which for  $b = \infty$  becomes  $x = \pm a$ , a hyperbola straightened out into a pair of right lines tangent at the vertices. The conjugate hyperbola,  $\frac{x^2}{a^2} - \frac{y^2}{b^2} = -1$ , on the same supposition ( $b = \infty$ ) becomes a pair of imaginary lines,  $x = \pm a\sqrt{-1}$ .

See SURFACES; see also references under "Cylinder" in the Index.

**CYMA**, in architecture, a molding of double curvature, whose profile is concave at one end, convex at the other. When the more projecting portion is concave it is known as a *cyma recta*, when convex as a *cyma reversa* (Gr. *kuma*, "wave"). See MOLDING.

**CYMATIUM**, the uppermost member of a classic cornice (*q.v.*), usually consisting of a projecting molding. In the Greek Doric the cymatium occurs only upon the pediment cornices, returning along the sides only the depth of the pediment coping which it decorates. It is in the form of an ovolo or projecting convex molding.

The cymatium also takes an ovolo form in the Tuscan order, a cavetto or concave form in the Roman Doric and a *cyma recta* form, or molding of double curvature, elsewhere. See MOLDING; ORDER.

**CYMBALS**, percussion instruments consisting of two circular metal plates struck separately or together. The use of cymbals is recorded in many ancient civilizations. They appeared in Israel about 1100 B.C. and are mentioned in the Bible. In China and elsewhere in Asia there were two kinds, the broad-rimmed cymbal, held horizontally, and the small-rimmed cymbal, held vertically. In the middle ages the term *cymbala* signified the small bells used to accompany a liturgical chant.

Modern orchestral cymbals derive from those used in Turkish military bands. In the 18th century Turkish military music enjoyed a vogue in central Europe and cymbals were introduced in works by Haydn (notably his "Military" Symphony, 1794), Mo-

zart and Beethoven. Of indefinite pitch, modern cymbals consist of a pair of thin circular plates from 14 to 18 in. in diameter, made from an alloy of copper and tin. The plates are domed for the inclusion of the knot of the holding strap and are slightly tapered to secure contact at the edges only.

Cymbals are played (1) by clashing the plates together; (2) by striking a single plate with a soft or hard-ended drum stick; (3) by producing a sustained note in the form of a tremolo on one suspended cymbal; and (4) by rubbing the plates together. The sounds produced cover a wide range of dynamics. In romantic music, e.g., Wagner's *Tannhäuser*, they are frequently used to mark a dramatic climax. Berlioz, Debussy and Ravel specified the use, in their scores of small cymbals producing high notes of a definite pitch. Twentieth-century composers introduced the pianissimo tremolo on a suspended cymbal. Jazz musicians employ several different ways of playing cymbals, including a method of striking them at elbow height with the help of a pedal mechanism. (J. BL.)

**CYNEGILS** (d. 641), king of the West Saxons from 611 to 641, succeeded Ceolwulf. With his son Cwichelm he won a victory against the Britons at an unidentifiable place called Beandun in 614. In vengeance for an attack made on him by an assassin sent by Cwichelm, Edwin of Northumbria came to Wessex with an army in 626 and defeated the West Saxons. Cyneigils and Cwichelm fought in 628 against Penda of Mercia at Cirencester, afterward coming to terms. Cyneigils was the first West Saxon king to be converted and was baptized at Dorchester-on-Thames in 635 by Bishop Birinus.

See *Anglo-Saxon Chronicle*; Bede, *Historia Ecclesiastica*, book ii, ch. 9, book iii, ch. 7. (D. Wk.)

**CYNEWULF** (d. 786), king of the West Saxons from 757 to 786, succeeded after the deposition of Sigeberht and later drove him into the Weald. He fought many battles against the Britons, and he seems mainly to have been independent of Offa of Mercia until they fought at Bensington (Benson, Oxfordshire) in 779. Until this date he held parts, at least, of Berkshire and Oxfordshire. He made several donations to the church and sent a letter to the missionary Lul in Germany. In 786 he was present when King Offa received the papal legates, but later in the year he was slain by Cyneheard, the brother of his predecessor Sigeberht, at Mere-tun, defending himself nobly against the men who had surrounded his chamber. The refusal of his followers to accept quarter and the similar loyalty of Cyneheard's followers to their lord made the incident a famous one.

See *Anglo-Saxon Chronicle*; *English Historical Documents*, vol. 1, ed. by D. Whitelock, pp. 23 ff., 162 ff., 165 ff., 457-459, 469, 770 (1955). (D. Wk.)

**CYNEWULF**, the author of four Old English poems preserved in late 10th-century manuscripts, two (*Elene* and *The Fates of the Apostles*) in the *Vercelli Book* (*q.v.*) and two (*The Ascension*, which forms the second part of a trilogy, *Christ*, and is also called *Christ II*; and *Juliana*) in the *Exeter Book* (*q.v.*). An epilogue to each poem, asking for prayers for the author, contains the runic characters which represent the letters *c, y, n, (e), w, u, l, f*. The names of five of these runic characters are nouns current in Old English, and, except in *Juliana*, are to be read in these senses in the passages containing the signature. The names of the runic letters *c, y, u*, meaning "torch," "bow," "bison," are not recorded except as rune names, and it is disputed whether they can be made to give sense in these meanings, or whether these runes merely stand individually for the author's name.

In *Juliana* and *Elene* the name is spelled "Cynewulf"; in *The Ascension* and *The Fates of the Apostles* the form is "Cynwulf," a variant of no significance for dating. The spelling *Cyne-*, instead of the earlier *Cyni-*, shows that the poet could not have been writing before the late 8th century if a Mercian, and not before the 9th century if a Northumbrian. A rhymed passage in the *Elene* proves that he came from one of these areas. Nothing is known of him outside his poems, as there is no reason to identify him with any of the recorded persons bearing this common name. The 8th-century bishop of Lindisfarne, with whom he has been identified, would have spelled the name with an *i*.

BY COURTESY OF (LEFT) THE METROPOLITAN MUSEUM OF ART, ROGERS FUND, 1908; (RIGHT) THE PREMIER DRUM CO., LTD.

(LEFT) COPPER CYMBAL FROM THEBES, EGYPT; GRECO-ROMAN PERIOD. IN THE METROPOLITAN MUSEUM OF ART; (RIGHT) MODERN ORCHESTRAL CYMBALS

The poems are all based on Latin sources, and it is probably to Latin influence that they owe their clarity and their smoothness of syntax. They display much metrical skill and a felicitous use of traditional poetic diction, especially in descriptions of voyages and battles.

As a narrator, Cynewulf does little to improve the low quality of his Latin originals, but in *The Ascension*, where the source is a homily of St. Gregory, he shows genuine religious fervour.

There have been many attempts to assign to Cynewulf other extant poems: the *Riddles* from the *Exeter Book*, the other two parts of the *Christ* trilogy, the *Phoenix* and the two poems on *Guthlac* (also in the *Exeter Book*) and the *Andreas* and *The Dream of the Rood* from the *Vercelli Book*. None carries conviction. *The Dream of the Rood* cannot be his, for some lines are inscribed on the Ruthwell cross, for which a date later than the early 8th century is highly improbable.

Detailed studies of metrical technique have led to a widely accepted belief that only the first part of *Christ* and *Guthlac B* could be added to the canon of Cynewulf's work, and even this cannot be proved.

**BIBLIOGRAPHY.**—For facsimiles and editions of the *Exeter Book* and the *Vercelli Book* see the articles on them. The individual poems are edited as follows: *Christ* by I. Gollancz (1892) and by A. S. Cook (1900); *Elene* by J. Zupitza (1877), by A. S. Cook (1919), by F. Holt-Hausen, 4th ed. (1936) and by P. O. E. Gradon (1958); *Juliana* by W. Strunk (1904) and by R. Woolf (1955); *The Fates of the Apostles* (with *Andreas*) by G. P. Krapp (1906). They are translated by C. W. Kennedy, *The Poems of Cynewulf* (1910). The best study is that of K. Sisam, "Cynewulf and His Poetry," in his *Studies in the History of Old English Literature* (1953). See also C. W. Kennedy, *The Earliest English Poetry*, pp. 198–266 (1943); C. Schaer, *Critical Studies in the Cynewulf Group* (1949), where full bibliographies of previous works are given; R. W. V. Elliott, "Cynewulf's Runes in *Christ II* and *Elene*" and "Cynewulf's Runes in *Juliana* and *The Fates of the Apostles*," *English Studies*, xxxiv (1953). (D. Wx.)

**CYNGHANEDD**, a Welsh word meaning, literally, "harmony," the name of the complicated system of consonantal correspondences and internal rhyme obligatory in the 24 strict metres of Welsh bardic verse. It had developed by the 13th century from the alliteration and internal rhymes used by the early bards, and has been practised ever since. There are four main patterns: (1) *Cynghanedd lusg*, in which the accented penultimate syllable rhymes with a preceding syllable, e.g., "Am ysbyrd dewr y céwri"; (2) *Cynghanedd sain*, in which there is an internal rhyme between the first and second parts of a line, and a consonant or consonants in the second part answered in the third, e.g., "Gwan y bardd/sýthardd/séithug"; (3) *Cynghanedd groes*, in which the consonants in the first half of the line are answered in the second, but the last syllable in each part must be different, e.g., "Y gŵr mŵr/w/e gŵr mŵr/wyn"; (4) *Cynghanedd draws*, which is the same in principle as *cynghanedd groes* except that consonants in the middle of the line are left unanswered, e.g., "A'i chwŵr (a'i medd) a'i cháriad." The system in all its variations is much more elaborate and complicated than the four basic patterns.

See J. Morris-Jones, *Cerdd Dafod* (1925); G. J. Williams and E. J. Jones, *Gramadegau'r Penceirddiaid* (1934). (T. Js.)

**CYNICS**, members of a sect of ancient "philosophers," distinguished by a way of life and by a few dogmas rather than by any coherent system of thought. Their name is derived from the Greek word for "dog" (*kuon*, adjective *kunikos*), in contemptuous allusion to their shameless and aggressive manners; but they accepted the opprobrious term, saying that it was their business as watchdogs of morality to terrify malefactors. The originator of the sect was Diogenes (*q.v.*), who in the second half of the 4th century B.C. set about exposing current conventions as false coinage. It was his object to get back to the "natural" life, which he saw as identical with the simple life. Ideally this would mean the disappearance not only of luxuries but also of organized communities, whose laws and customs must be accounted "conventional" (even the family is an unnatural institution: in the state of nature men and women would be promiscuous and the children a common concern of all). He himself lived as a vagabond pauper, sleeping in public buildings and begging his food. This was not a life that all men could be desired to lead or that was led by all

Cynics: Diogenes' object was to give an extreme example of how one could be happy and independent, although absolutely destitute. "Self-sufficiency," to have all that one needs within oneself, is the first of the Cynic's aims. To this he adds "shamelessness," which means disregard for the conventions which prescribe that actions harmless in themselves may not be performed in all circumstances; and "outspokenness," which is not merely an avoidance of conventional euphemism but also part of the armoury of the Cynic in his missionary task of exposing vice and conceit and stirring men to reform. Further, just as physical excellence comes from training, training (*askesis*, from which is derived "asceticism") is necessary for moral excellence; it takes the form of inuring oneself to hardship and to privation and of developing resistance to the pressures of pleasure and pain. Self-sufficiency and training for virtue had earlier been preached by Antisthenes (*q.v.*), to whom Diogenes acknowledged an indebtedness, but the extreme anticonventionalism and the reforming zeal which are characteristic of the Cynic are Diogenes' own contributions.

Zeno, the founder of Stoicism, was strongly influenced by Diogenes' pupil Crates of Thebes (*see CRATES*), who was known as "gatecrasher" from his habit of intruding into families with his advice; but Zeno perceived the unsatisfactoriness of the Cynic's "virtue," which, being no more than a contempt for the usual objects of desire (wealth, honour, love, physical pleasures, etc.), was essentially a negative conception, even if presented in the guise of being master of one's will and impregnable to fortune. By his recognition of "preferred" things he opened the way to a positive system of ethics.

The most important Cynic of the 3rd century B.C. was Menippus (*q.v.*), who developed the genre of *spoudaiogeloion* (a mixture of jest and earnest), which Crates had initiated. Marcus Aurelius calls him "the mocker of mankind": indeed in any Cynic's view, most human activities involve a conceited delusion that it is his duty to expose. The nature of Menippus' works must be guessed from their titles and from the fact that Lucian found inspiration in them: they included a *Journey to the Underworld* (where the Cynic gloated over the disappearance of this world's illusions, wealth, power and beauty); *Letters from the Gods*; *The Sale of Diogenes* (a fiction later taken for a fact); and various mockeries of scientists and philosophers. Chance has preserved more of a less famous author, Cercidas of Megalopolis. He played an active part in the politics of the late 3rd century and, instead of merely mocking the rich and the wicked (whom he considered to be identical), proposed to usurp the neglected function of heaven and to distribute their wealth to the virtuous poor. This kind of activity may have been unusual among professed Cynics, but his attacks on other philosophers for futility, his disapproval of the charms of music and his praises of Diogenes are quite in the authentic style of the sect.

Another literary figure was Bion, from Borysthenes on the Dnieper, who developed a style of popular preaching, made palatable by similes, anecdotes, allegories, etc. A Cynic phase left its mark on his ideas, and his style in turn influenced later Cynics who wished to reach the multitude.

How many followed the Cynic way of life in the Hellenistic period is not known, but such persons were prominent in the Greco-Roman civilization of the early empire. There were many who brought the name of Cynic into disrepute. It was all too easy for a poor man to make a virtue of necessity and, calling himself a Cynic philosopher, to enjoy the licence of "shameless outspokenness" at the expense of the prosperous, to the admiration of the more simple-minded proletariat. Doubtless such elements were to be found among the Cynics who caused riots at Alexandria in Trajan's time. The other extreme is represented by the Stoic Epictetus' stirring picture (*Discourses*, iii, 22) of the ideal Cynic, who renounces all comfort, all family life, because he is God's soldier and must be free from impediments that might interfere with the bringing of God's message to the whole human family, to whom he is father and brother.

Stoicism and Cynicism were commonly associated (Juvenal speaks of them as virtually identical) in an age when many Stoics emphasized endurance, abstinence and internal independence at

the expense of those more positive aspects of Zeno's teaching that had distinguished him from his master Crates. But a survey of the more renowned Cynics of the 2nd century A.D. makes it clear that they had no common system of philosophy. Demonax, who lived at Athens about A.D. 70-170, devoted himself, like Epictetus' ideal, to the service of mankind and in particular to the restoration of good will, but, unlike him, was an atheist and a municipal politician. Religious shams were also attacked by Oenomaus, from Gadara in Palestine, who wrote against oracles and prophecies. On the other hand, Peregrinus Proteus (whom Lucian treats, too superficially, as a mere charlatan) at one time combined Christianity with his Cynicism and later adopted elements from Neopythagoreanism and from Greek and oriental religions. Finally, declaring that, having lived like Heracles (who was a Cynic hero for his labours on mankind's behalf), he would die like him too, he burned himself to death after much publicity and amid scenes of the wildest excitement at the Olympic games of A.D. 165. He certainly intended to set a memorable example of contempt for death; he may also have hoped for the cult that was established in his memory by those who supposed him to have passed through the purification of the flames to a higher form of life.

A recurring characteristic among Cynics of the early Roman empire is that they publicly attacked the emperor, but this does not imply any common political program. Some emperors' private lives and public acts provided ample material for denunciation, and even "good" emperors were objectionable because they pandered to their subjects' material desires. Thus Peregrinus obliged Antoninus Pius to expel him from Rome and, in Greece, denounced the philanthropic millionaire Herodes Atticus for providing Olympia with a water supply.

There were Cynics to the end of the ancient world. The emperor Julian, while favouring and practising a pious Cynicism as the "natural universal philosophy," upbraids contemporary Cynics with hypocrisy and greed—old charges these—and joins them with the hated "Galileans." In fact, although there were still atheists among them, other Cynics were professed Christians, and the sect was recommended to the early church by its neglect of the body, by its contempt for civil authority and by its self-dedication to the task of preaching reform to a universal human brotherhood.

See K. von Kritz, "Quellenuntersuchungen zu Leben und Philosophie des Diogenes von Sinope," *Philologus*, supplement 18 (1926); D. R. Dudley, *A History of Cynicism from Diogenes to the 6th Century A.D.* (1937). (F. H. SH.)

**CYNOCEPHALUS**, the generic name applied to the flying lemurs, also commonly called cobegs or colugos. These oriental animals are a singular group of mammals usually placed within the Insectivora (see INSECTIVORE) as a distinct suborder, but sometimes ranked as a separate order (Dermoptera). The name pertains strictly only to the Philippine species, *C. volans*, formerly called *Galeopterus*. According to the rules of zoological nomenclature, the latter name had to be replaced by *Cynocephalus*; this change has caused confusion because the term *Cynocephalus* had also been employed for the baboons (*q.v.*).

In appearance colugos resemble large flying squirrels and have similar habits, being arboreal climbers and gliders with extensive lateral gliding membranes and large five-toed feet, webbed and clawed. However, the form of the head and the nocturnal habits recall the lemurs. The tail is relatively short, but connected by skin folds with the hind limbs, as in bats. Most peculiar are the teeth, which number 34. The lower incisors are directed forward and present a comblike structure due to multitudinous enamel foldings; the lateral pair, like the canines, are double-rooted. Canines are lacking in the upper jaw. Cheek teeth bear sharp cusps and include premolars and molars.

Internally the large intestine is longer than the small and there is a huge caecum of complex structure correlated with the diet of leaves; but the stomach is simple, though more specialized than in insectivores. The brain resembles that of insectivores in the exposure of the *corpora quadrigemina*, but each hemisphere is marked by two longitudinal furrows—a combination not met with in any other mammal.

Besides the Philippine species, a series of other forms ranges from Burma, Thailand and the Malay peninsula to the Malay archipelago from Sumatra to Borneo. These forms are all regarded as races of a single species, *Galeopterus variegatus*, distinguished by its larger upper incisors, shorter ears and smaller skull.

(W. C. O. H.)

**CYNOSCEPHALAE** ("Dogs-heads"), the name of a range of hills in Thessaly, Greece (about 7 mi. W. of modern Volos), the site of the defeat by the Theban general Pelopidas (*q.v.*) in 364 B.C. of Alexander, tyrant of Pherae, and also in 197 B.C. of a more celebrated battle, the final victory of Rome over Philip V of Macedonia in the Second Macedonian War.

The Roman army under Flamininus (*q.v.*) numbered about 26,000 men, of whom about 8,000 were Greeks; it was stronger than the enemy in cavalry and had some war elephants. Philip's army numbered about the same; his phalanx comprised 16,000 men. After some skirmishing near Pherae on ground that proved unsuitable, Philip, who needed supplies and level ground for his phalanx, marched westward along the northern slopes of some hills which ended in the low range called Cynoscephalae. For three days Flamininus marched along the southern slopes, but out of touch with the enemy. When Philip turned southwest to cross Cynoscephalae toward Pharsalus, his advance force blundered in a mist into some Romans. A fluctuating skirmish developed into a pitched battle. Flamininus drew up his line along the south of the hill, while Philip advanced his centre and right wing over the rough ground, leaving his left wing under Nicanor to follow as soon as possible. Flamininus, however, had left his own right wing stationary, and led his left up the hill and drove back Philip's mercenaries. Unable to wait for Nicanor, Philip launched his main phalanx force, before whose weight the Roman left gave ground. Thereupon Flamininus galloped over to his own right wing, which routed Nicanor's wing before it could deploy. With each side victorious on one wing, the issue hung in the balance, when an unknown Roman tribune saw what ought to be done. Detaching 20 maniples from the rear of the victorious Roman right wing, he led them against the flank and rear of the Macedonian right. The day was lost. Philip fled, leaving 8,000 dead and 5,000 captured. The delay of his left wing, the roughness of the ground, a tribune's initiative, and the greater flexibility that Scipio Africanus had given to the legion had secured the victory.

(H. H. SD.)

**CYPERACEAE**, the sedge family of grasslike plants, often confused with the grasses and the rushes. Most sedges are perennials that have long creeping rootstocks or form dense clumps, but some are annuals. They have three-sided leafy or leafless herbaceous stems that range from a few inches to twelve feet in height and differ from grasses (Gramineae) in the three-ranked leaves with closed sheaths. From the rushes (Juncaceae) they differ in having a leathery or hard-walled fruit with a single seed. The flowers of the sedges are minute, and consist of only a pistil, two or three stamens and sometimes an appendage of bristles. The flowers are clustered in spikelets, and each flower is commonly subtended by a coloured scale.

Practically all sedges are wind-pollinated. They are widespread throughout the world, and they play an important part in the formation of peat, especially in boreal regions.

About 70 genera and 4,000 species are known. *Cyperus*, with about 600 species, predominates in tropical marshes, and includes

ROTHERFORD PLATT  
FIG. 1.—COTTON GRASS (ERIO-  
PHORUM POLYSTACHION)

papyrus (q.v.; *C. papyrus*), the bulrush of the King James Bible and the original source of paper. *C. esculentus*, known as chufa, is cultivated for the edible tubers.

*Carex*, with over 1,000 species, predominates in temperate regions, and grows in a great variety of habitats. More than 400 species are known from North America alone.

*Scirpus* includes the true bulrushes, such as the tule of California, and the Bolivian *tatora*, used in making reed boats. The true bulrushes occur in lakes, ditches and marshes, and have spongy, green, three-sided or cylindric stems, up to an inch in thickness and one to eight feet high. They are usually leafless with a terminal branched inflorescence.

The flowers of cotton grasses (*Eriophorum*) have elongated silky bristles that are ornamental in bogs of the northern regions. The spike rushes (*Eleocharis*), with leafless stems topped by small flowering heads, are common in pools. They include *E. dulcis* (or *tuberosa*), the tuberous roots of which are the water chestnuts of Chinese restaurants (to be distinguished from the water chestnut *Trapa natans* eaten chiefly in the orient).

JOHN H. GERARD

FIG. 2.—UMBRELLA PLANT (CYPERUS ALTERNIFOLIUS)

Sedges also include the common saw grass (*Mariscus jamaiensis*) of the Florida Everglades and *Mapania*, a peculiar broad-leaved plant that forms undergrowth in tropical forests.

The strawlike stems of some tropical sedges, especially bulrushes and species of *Eleocharis*, are used for making mats and articles of clothing. In tropical savannas the whitened buttonlike heads of various kinds of sedges are conspicuous elements of the landscape. Sedges are also conspicuous in late summer in damp places in the Atlantic coastal

(H. K. SN.; X.)

**CYPRESS**, the common name given to several genera of evergreen, aromatic trees and shrubs belonging to the coniferous family Cupressaceae, but especially to species of *Cupressus*, the true cypress.

**True Cypress.**—These trees, which are indigenous to North America, southern Europe and Asia, feature scalelike overlapping leaves, usually in four ranks; few-scaled catkins; cones consisting of from six to ten peltate, woody, terminally bossed scales; and numerous small, winged seeds. All species exude a resin but no turpentine.

The Italian cypress (*Cupressus sempervirens*) has been well known throughout the Mediterranean region since classic times. It is a tapering tree resembling the Lombardy poplar; its branches are thickly covered with small, imbricate, shining, green leaves; the male catkins are minute; the cones are between 1 and 1½ in. in diameter, sessile and generally in pairs, and are made up of large angular scales, slightly convex exteriorly, and with a sharp point in the centre.

The tree grows to a height of 90 ft. in its native soil. It thrives best on a dry, deep, sandy loam, on airy sheltered sites at no great

elevation. The timber is hard, close-grained, of a fine reddish hue and very durable.

The cypress, which is incapable of developing stump sprouts once the tree is cut down, was regarded as a symbol of the dead, and perhaps for that reason was sacred to Pluto. The tree grows straight, or nearly so, and has a gloomy and forbidding but wonderfully stately aspect. With advancing age its foliage becomes almost black.

The finest representative of the genus *Cupressus* in California is the Monterey cypress (*C. macrocarpa*). It is a tree of beautiful symmetry, becoming 150 ft. in height, with a trunk 8 ft. to 10 ft. in circumference. It grows rapidly, even on poor soils, and thrives best near the sea. Other Californian species are *C. goveniana* and *C. macnabiana*, which are much smaller trees than the Monterey cypress. *C. funebris* is a native of the north of China, where it is planted near pagodas.

**Other Cupresses.**—The Port Orford white cedar (*Chamaecyparis lawsoniana*), native to south Oregon and north California, is commonly known as Lawson cypress to horticulturists. *Chamaecyparis nootkatensis*, the Nootka sound cypress or Alaska cedar, is a hardy species reaching a height of from 80 ft. to 100 ft. *C. obtusa* of Japan is a tall tree reaching 100 ft. in height and widely planted by the Japanese for its timber—one of the best for interior construction. It is also cultivated by them in a dwarf form not exceeding a foot in height.

The bald cypress, *Taxodium distichum*, a deciduous conifer, is a member of the family Taxodiaceae, a native of the southern United States and Mexico. It is a lofty tree reaching a height of about 170 ft., with a massive trunk 15 ft. or more in diameter, growing in or near water. The lower part of the trunk bears huge buttresses, each of which ends in a long-branching, far-spreading root, from the branches of which arise the peculiar knees above the level of the water. The knees are of a soft spongy texture and have been thought to act as breathing organs, supplying the roots with air. Some authorities assert that their function is largely mechanical and that they give greater stability to the standing tree. The stout, horizontally spreading branches give a cedarlike appearance; the foliage is light and feathery; the leaves and the slender shoots which bear them fall in the autumn.

(LEFT) BY COURTESY OF CHICAGO NATURAL HISTORY MUSEUM; (RIGHT) J. HORACE MCFARLAND CO.  
MONTEREY CYPRESS (CUPRESSUS MACROCARPA): (LEFT) BRANCH WITH FRUIT; (RIGHT) GROWTH FORM OF TREE

The cones, about the size of a small walnut, bear spirally arranged imbricated peltate scales which subtend the three-angled, winged seeds. The wood is light, soft, straight-grained and easily worked; it is very durable in contact with the soil, and is used for railway ties, posts and fencing and for construction.

In Mexico the bald cypress occurs in the lower Río Grande valley, furnishing valuable timber locally. Its durability and resistance to water are remarkable.

The geological history of cypress dates back to the Upper Cretaceous, the evidence being that the group was derived from the pine group during the Mesozoic.

(E. S. HR.; X.)

**CYPRIAN, SAINT** (CAECILIUS CYPRIANUS, called THASCIUS) (c. 200–258), bishop of Carthage and martyr, is best known for his repudiation of heretical baptism and for his dispute with

Pope Stephen on the subject. He was born, probably at Carthage, of a wealthy pagan family of good standing, and was a worthy product of the oratorical education of the day. His conversion to Christianity (c. 246) transformed his life; he sold most of his property to relieve the poor and himself adopted complete chastity. His study of the Scriptures (exemplified in his *Testimonia ad Quirinum*) now displaced the profane authors, whom he never quotes, whereas he draws freely on both Testaments. In 249 he was chosen bishop of Carthage, and during the next ten years he led his flock through the persecution of Decius, defended the unity of the church against two schismatical movements, was the soul of the city's morale during a devastating plague and was beheaded as a martyr in the persecution of Valerian on Sept. 14, 258.

The corpus of Cyprian's works consists of treatises and letters. The "treatises" are mostly pastoral addresses (e.g., *The Lapsed, Virgins and Their Apparel, Generosity to the Poor*); the letters, 82 in all, include 14 addressed to him and two others of contemporary interest. The official report of his execution and the sketch of his life and martyrdom by Pontius, his deacon, were added to the corpus, as also some spurious treatises and poems. The genuine works reveal the Christian life in Carthage, the letters throwing valuable light also on Rome, Spain, Gaul and even Cappadocia.

Misled by Jerome, many writers have exaggerated Cyprian's dependence on Tertullian. In style and mentality the two are poles apart; some of Cyprian's treatises may even have been intended as antidotes to those of Tertullian. Again, his use of Stoic commonplaces and his praise of constancy under torture do not make him a follower of the Stoics, whose main tenets he explicitly denounces (e.g., when he condemns Novatian's callous attitude to the lapsed).

Cyprian's own strictness is tempered by genuine human understanding; it is not the Stoic *apatheia* ("imperturbability") but union with Christ which is to be the martyrs' strength. It is always the Christian values that fill his mind: baptism, Eucharist (real presence and sacrifice), penance, charity and patience—all inspired by the Scriptures and the example of Christ.

His conception of the unity of the church has been the subject of much controversy. His view that heretics could not baptize or ordain—not having the Holy Spirit themselves, how could they impart it to others?—was unanimously endorsed by 86 bishops in his council of 256 (the first of its kind of which the minutes survive), and he vehemently attacked Pope Stephen who condemned the rebaptism of such converts. Some have held that Cyprian's outburst was but a momentary lapse from his normal recognition of papal supremacy. Others, in view of his insistence on the rights of bishops, have seen in him a champion of episcopalianism (not to mention sacerdotalism). Both these views would seem to involve anachronism, nor can the problem be solved by appealing to *De catholicae ecclesiae unitate*, ch. 4, which is extant in two recensions, one propal in appearance, the other episcopalian; Cyprian probably was the author of both. He could see that the unity of the church depended on "the concord of the bishops," but his ecclesiology went no further. He took a practical view of things, recognizing Rome as the *de facto* centre of the church without scrutinizing the nature of its authority. He recognized that Pope Cornelius had the right to expect reports from him on important matters; he also called on Stephen to intervene in the church of Gaul. But he was quite unconscious of any inconsistency in his own refusal to obey Stephen in the matter of rebaptism. In fact Rome bore him no grudge and, though Cyprian's baptismal outlook was eventually rejected by the church, he himself is named in the earliest list of Roman feast days (Sept. 16) and in the Roman Mass, and he was quoted as an authority by the Council of Ephesus (431).

**CYPRINODONT**, any of the small fishes belonging to the order Cyprinodontiformes (Microcyprini). All cyprinodonts are characterized by being soft-rayed, having abdominal pelvic fins and lacking a duct to the air bladder. The small protractile mouth usually opens on the upper surface of the flat-topped head. About 400 species are known, none of which exceeds a foot in length; they are found in all warm countries but are especially abundant in America. Many species are marine, but they frequent lagoons and estuaries; others are confined to fresh water. There are seven families, of which the Cyprinodontidae, the egg-laying top minnows or killifishes, occur in Africa, southern Europe and Asia as well as in America.

BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

EGG-LAYING TOP MINNOWS (*TOMEURUS GRACILIS*): PREPARING FOR MATING. FEMALE ABOVE, MALE BELOW WITH GONOPodium (ANAL FIN) EXTENDED

The cyprinodonts are favourites of tropical-fish aquarists because of their small size, pretty colours and lively habits. Courtship and pairing are general throughout the group, and in many species the sexes are very dissimilar, the males being brilliantly coloured and having large and beautifully ornamented fins.

*Cynolebias*, of South America, is unique among fishes, the dorsal fin of the male being not only much larger than that of the female but also having many more rays. The eggs of these fishes are able to withstand the annual drying that occurs in shallow tropical pools.

The live-bearing (viviparous) families are American, and in them the anal fin of the male is modified into an intromittent organ. The guppy (*Lebistes reticulatus*), mosquito fish (*Gambusia affinis*), and many other cyprinodonts that devour mosquito larvae have been used to control those pests in some tropical and temperate areas. The male swordtail (*Xiphophorus helleri*) has the lower half of the caudal fin produced into a long pointed process. The spotted platy (*X. maculatus*) has many colour variants. Hybrids between the two last-named fishes are useful in cancer studies. Molly (*Mollienesia*) males often have longer and more colourful dorsal fins than the females, but the fin numbers are equal in the sexes. The Amazon molly (*M. formosa*) is essentially exclusively female and "borrows" sperm from related species to initiate egg development. In one of the most curious types, the surface-swimming four-eyed fish (*Anableps*), of Central and South America, the eyes project above the head and are divided by a black horizontal band into an upper part for vision in the air and a lower for vision in the water. Spermatophores are characteristic of the viviparous members of the group. The blind cave fishes (*Amblyopsidae*) of North America are related.

**CYPRIPEDIUM**, a genus of beautiful hardy orchids, commonly called lady's-slippers or moccasin flowers, nearly always found growing in soil (unlike many of the epiphytic orchids). They are cultivated in the greenhouse and outdoors for their flowers, white, yellow, pink or rose-purple slipper-shaped blossoms. See LADY'S-SLIPPER; ORCHID.

**CYPRUS** (Greek KYPROS; Turkish KIBRIS), a republic within the Commonwealth of Nations and the third largest island in the Mediterranean sea, lies 60 mi. W. of Syria and 40 mi. S. of Turkey. With an area of 3,572 sq.mi. it is 140 mi. long in an east-west sense, about one-third made up by the narrow Karpas peninsula, and is 60 mi. at its greatest width. The coast line, 486 mi. in

length, is indented and rocky but never mountainous and includes a great number of sandy beaches which are extensive along the main bays.

## I. PHYSICAL GEOGRAPHY

**1. Physical Features.**—In spite of its small size Cyprus has a large variety of rocks ranging from perhaps Precambrian to Recent. The structure of the island comprises features deriving from both the Caledonian and the Alpine orogeny and including other features reminiscent of the East African rift valleys. The oldest rocks are in the southwest while as a rule the younger ones are away from the mountain areas. The rocks of the Troodos massif in the southwest, at the highest part of the island and at another area, are plutonic in origin and include gabbros and granophyric rocks; but the most extensive rock is the diabase. The diabase is the result of volcanic activity of probably Devonian Age. Forming a broken ring round the Troodos massif is the extensive Pillow Lava series of Devonian to Permo-Carboniferous Ages. South of the massif, and to a much lesser extent north and east of it, chalks, marls and chalky limestones of the Lapithos group (Upper Cretaceous and Eocene) and the Pakhna formation (Miocene) outcrop.

The highest parts of the Northern or Pentadaktylos mountain range are of Hilarion limestone, a massive limestone of Triassic Age. This is flanked by the Kythrea formation which is made up of marls streaked by limestone bands. Between the two ranges and in coastal plains, especially in the south, outcrop the youngest (Plio-Pleistocene and Recent) rocks of Cyprus—marls, sandstones, conglomerates, alluvium and gravels.

BY COURTESY OF PUBLIC INFORMATION OFFICE, CYPRUS

IRRIGATION DAM IN THE TROODOS MASSIF

Cyprus can be divided into five morphological regions.

*The Northern or Pentadaktylos Range* rises abruptly a few miles east of Cape Kormakiti (ancient Crommyon) and attains its maximum height (Kyparissovouno, 3,357 ft.) almost at once, becoming generally lower eastward, while in the Karpas it ceases to be a mountain. It is a slender, steep-sided but elegant range with beautiful colours when the sun is low. North of it is to be found the very narrow strip of coastal plain with level-topped islands offshore, the whole landscape being a fractured and foundered former raised beach. South of the Pentadaktylos range the Miocene flysch and later rocks form a striking hummocky topography, the result of folding by pressure from the north.

*The Central Lowlands*, often known incorrectly as Messaoria, show considerable variations and include alluvial fans in the southwest; extensive mesas and buttes separated by very wide, alluvium-strewn valleys and basins in the central areas; and the joint flood plain of the Pedieos-Yialias rivers in the east. This flood plain is the Messaoria (or rather Messarka) proper.

*The Troodos Massif*, a vast, bulky and high (Khionistra peak or Mt. Olympus, 6,403 ft.) mountain range, is an old land mass extensively dissected and rejuvenated.

*The Southern Uplands or White Plateaus* are composed of chalks and marls and fall in steps from over 3,000 ft. close to the massif to almost sea level. Deep, trenchlike valleys cut this region into vast blocks of plateau country.

*Coastal Plains* of fertile alluvium represent old bays of the receding Southern uplands or raised beaches. These coastal plains are most extensive in the south and west of Cyprus and carry important towns.

The drainage of Cyprus radiates from the massif system. Most of the rivers have very steep and short courses to the sea but a few cross the Central lowlands and play an important part in the life of the island.

**2. Climate.**—Though an island, Cyprus comes under continental influences due to the presence of vast land masses on almost all sides. Clear skies, abundant sunshine and low erratic rainfall are the result. The duration of sunshine at its shortest exceeds 50% of the possible. Annual rainfall varies from below 12 in. in the west of the Central lowlands, and 16 in. in most lowland areas to 25–40 in. in upland and mountain areas. Rainfall is concentrated in the three winter months, December to February, which account for 65% to 80% of the annual amount. Rainfall is erratic in its distribution in time and place and serious droughts occur at least once in a decade. Annual rainfall as low as four inches has been recorded.

Snow is a regular feature in the highest parts of the Troodos massif. Winters are mild, and in some years no frost at all occurs in the lowland areas. The mean temperatures for the coldest month vary from 55° F. in the coastal areas and 50° in inland low-lying areas to 40° in the upper parts of the Troodos massif. The summer months, normally rainless, are hot and dry inland and hot and humid on the coast. The most comfortable temperatures are experienced in the upper parts of the massif. The day temperatures are excessive (112° in the shade was officially recorded in Nicosia in 1956) and for 10 to 15 days in the year they exceed 100°. The mean temperatures for the hottest month are 85° in inland lowland areas, 80° on the coast and 72° in the upper reaches of the massif.

**3. Vegetation and Animal Life.**—It is doubtful whether any original vegetation is now left in Cyprus. Such evidence as exists indicates affinities with that of surrounding continents. The exclusive Cypriot plant is *Quercus alnifolia*, an evergreen oak widespread in forest and scrub areas. By far the most prevalent forest tree is the Aleppo pine.

The cedar, after having reached near extinction, is spreading as a result of state protection. Most of the remaining forest in Cyprus now survives in the Troodos massif. The Aleppo pine and cypresses are found also in the Pentadaktylos range. Apart from the visits of birds of passage Cyprus has little wild fauna left other than hares and a race of the Persian mouflon (distinct from the mouflon of Corsica and Sardinia), in danger of extinction and protected by the state.

(D. CH.)

## II. HISTORY

**1. Early History and Archaeology.**—The earliest remains so far discovered in Cyprus belong to the Late Neolithic (New Stone) Age. An important settlement not far from the south coast, near the village of Khirokitia, has been dated by carbon-14 tests to the mid-6th millennium B.C. Architecture is represented by beehive dwellings and the utensils in use were of stone. Flint and obsidian implements were current while stone celts were found in great numbers. This earlier period, which may be called pre-ceramic, was followed by another period marked by well-made pottery with painted patterns. A new era is represented by the introduction of combed pottery which has been mostly found at the settlement of Sotira about 5 mi. N. of the classical town of Curium near the south coast. The Sotira culture has been dated to the second part of the 4th millennium B.C. In the early 3rd millennium the combed pottery was gradually replaced by painted pottery mostly found at the settlement of Erimi not far from the south coast. Houses were circular and the general aspect of the culture shows substantial development. Copper then made its first appearance. Toward 2500 B.C. red-and-black pottery, probably influenced by the Khirbet Kerak ware, began to take the place of the painted wares and in the 23rd century pottery shapes of western Anatolian types found their way into the island, probably introduced by people in search of copper. This period represents the Early Bronze Age which is followed by the Middle Bronze Age (early 2nd millennium B.C.), characterized by the return of painted pottery. In the Late Bronze Age (1600–1050 B.C.) Cyprus became the emporium of the east. The most important event during this period was the appearance of Mycenaean traders about 1400 B.C., followed by successive waves of Achaeans, who colonized the island and introduced Greek culture and language.

During the Late Bronze Age Cyprus appears in Egyptian records under the name of Asi as a conquest of Thutmose III of Egypt (c. 1500 B.C.). But Alashiya (Alasia), mentioned in Egyptian, Hittite and Mesopotamian records, has also been identified as Cyprus, although doubts have been expressed on this identification.

The cultural characteristics as reflected mostly in the ceramic production of the first part of the Iron Age (c. 1050–950 B.C.) show a fusion of Cypriot and Achaean but also of Syro-Anatolian elements. It appears, however, that the Achaean element gained the upper hand. The Cypriot kingship as it is known from later evidence was established by the Achaean colonists, although pre-Achaean kingdoms did exist in Cyprus; for example, at Paphos (*q.v.*). The character of the kingship, originally Mycenaean, developed later into an autocracy of oriental type with the king as the head of the state, although Idalion enjoyed a more democratic form of government. Art as reflected in pottery and other crafts of the early Iron Age is first dominated by the Achaean-Mycenaean features, but later (950–700 B.C.) Cypriot characteristics come to the fore. Commercial relations with the east (Syria, Palestine, Egypt, Asia Minor) were at first rare, but from the 9th century onward became closer. Sidon and Tyre on the Syrian coast and Tarsus in Cilicia were centres through which Cypriot wares were transmitted to the interior of the continent. The relations with Greece followed a similar course, Rhodes being the main intermediary between Cyprus and the Greek mainland and islands.

**From 800 B.C. to A.D. 400.**—The beginning of Phoenician penetration into Cyprus may be dated to about 800 B.C., although a funeral inscription of the 9th century B.C. shows the appearance of Phoenician elements already in that century. Citium (*q.v.*; Kition), a Tyrian colony, was the main centre of Phoenician activity and the overwhelming majority of Phoenician inscriptions were found in that city.

**Assyrian Domination.**—The year 709 B.C. marks the end of political independence with the submission of the Cypriot kings to the Assyrian king Sargon II. The event was commemorated in Dur Sharrukin (Khorsabad) as well as in Cyprus, where, at Citium, a stele, now in Berlin, was erected. On the stele Cyprus is referred to as Yatnana; *i.e.*, the isles of Danaoi.

The hold of Assyria over Cyprus continued during the reigns of Sargon's successors. Thus Esarhaddon's prism, written in 673–672 B.C., refers to ten kings and kingdoms of Cyprus among which

RUINS OF THE GYMNASIUM AT SALAMIS. ORIGINALLY HELLENISTIC, IT WAS DESTROYED MANY TIMES AND WAS REBUILT BY JUSTINIAN AS A BATH, 6TH CENTURY

is Qarthadast (Citium). Although Cyprus appears as one of the countries paying tribute to Ashurbanipal (667 B.C.), the Assyrian domination may have ended in 669. From about that date Cyprus had almost 100 years of virtual independence—one of the most brilliant periods of Cypriot culture (the first part of the Cypro-Archaic period). The power of the kings became greater, a fact reflected in the monumental tombs built of ashlar masonry. Palaces were built and shipbuilding and mining attained a high level of production. Ceramic art produced some of the island's finest and most richly ornamented vases, while metalwork, as evidenced by some remarkable silver bowls, reached great perfection under oriental (mostly Egyptian or Phoenician) influence. The output of Greek epic poetry is noteworthy; Stasinus, to whom the epic called *Cypria* is attributed, belongs to the 7th century.

Commercial and cultural relations with the east and west were intensified and Cyprus maintained close intercourse with Rhodes, which continued to be the chief steppingstone of Cypriot commercial expansion to the west. Mainland and eastern Greek pottery found its way to Cyprus and Cypriot products were widely distributed, thus transmitting oriental characteristics to Greek art.

**Egyptian and Persian Influence.**—Following the breakup of the Assyrian empire, Egypt became the great power. Cyprus was necessary to Egypt for minerals and material for shipbuilding, and Ahmose II (569–526) conquered the island in about 560. This meant a new orientation of Cypriot culture, and the influence of Egypt is reflected mostly in the sculpture and the increased importation of Egyptian goods, chiefly from the Greek colony of Naukratis in the Egyptian delta. The Cypriot kings and kingdoms were allowed to exist but they paid tribute to the Egyptian king.

The annexation of Egypt by Cambyses of Persia in 525 B.C. was preceded by the voluntary surrender of Cyprus, which formed part of Darius' fifth satrapy, but the Cypriot kings were left undisturbed and struck their own coinage. The Greek cities joined the Ionian revolt c. 498 B.C., but the Phoenician colonies, Citium and Amathus (*q.v.*), remained loyal to Persia. The rising was soon put down; in 480 Cyprus furnished 150 ships to the fleet of Xerxes and remained subject to Persia during the 5th century. But the Greek cities retained monarchical governments throughout. The principal Greek cities were then Salamis (*q.v.*), Curium, Paphos, Marion, Soli (*q.v.*), Kyrenia and Chytri. Phoenicians held Citium

and Amathus on the south coast, Tamassus and Idalium in the interior. At the end of the 5th century a fresh Salaminian league was formed by Evagoras (*q.v.*), who became king in 410, aided by the Athenian Conon after the fall of Athens in 404, and revolted openly from Persia in 386. Athens again sent help. But the Phoenician states supported Persia as before, the Greeks were divided by feuds and in 380 the attempt failed; Evagoras was assassinated in 374, and his son Nicocles died soon after. After the victory of Alexander at Issus in 333 all the states of Cyprus welcomed him.

These political events are reflected in the cultural and artistic development. Architecturally, this period is exemplified by the palace of Vouni, the history of which is interwoven with events of the 5th century. Excavations at Kouklia (Palaipaphos) have shown more evidence of the political history of these times. Sculpture, after first producing remarkable works under Ionian

influence encouraged by the annexation of Cyprus to the Persian empire, passed into relative stagnation. Evagoras' accession to the throne of Salamis encouraged Hellenic cultural relations but the effects were meagre. It was at this time that Greek symbols and alphabet were introduced into the local coinage.

After Alexander's death in 323 Cyprus passed, after several rapid changes, to Ptolemy I, king of Egypt. Under Ptolemaic rule Cyprus was usually governed by a viceroy of the royal line, but it gained a brief independence under Ptolemy Lathyrus (107–89 B.C.) and under a brother of Ptolemy Auletes (80–58 B.C.). The great sanctuaries of Paphos and Idalium and the public buildings of Salamis, which were wholly remodeled in this period, have produced but few works of art. It is in this period that Jewish settlements are first heard of; these later became well populated. Following the annexation of Cyprus to Ptolemaic Egypt the local coinage ceased to exist and artistic production, mostly illustrated by sculpture, was chiefly dependent on the workshops of the Hellenistic world.

**Roman Period.**—In 58 B.C. Rome, which had made large unsecured loans to Ptolemy Auletes, annexed the island. Under Rome, Cyprus was at first appended to the province of Cilicia; after Actium (31 B.C.) it became a separate province, which remained in the hands of Augustus and was governed by a *legatus Caesaris pro praetore* as long as danger was feared from the east. In 22 B.C., however, it was transferred to the Senate, so that Sergius Paulus, who was governor in A.D. 46, was rightly called proconsul.

The persecution of Christians on the mainland after the martyrdom of St. Stephen drove converts as far as Cyprus; and soon after converted Cypriot Jews such as Joses the Levite (better known as Barnabas) were preaching in Antioch. The latter revisited Cyprus twice, first with Paul on his first journey in A.D. 46 and later with Mark. In 115–117 the Jews of Cyprus, with those of Egypt and Cyrene, revolted, massacred 240,000 persons and destroyed a large part of Salamis. Hadrian, afterward emperor, suppressed them and expelled all Jews from Cyprus. For the culture of the Roman period there is abundant evidence from Salamis and Paphos and from tombs everywhere, and from the glass vessels which almost wholly supersede pottery in tombs. Of the sculptural works the most remarkable are the bronze statue of Lucius Septimius Severus in the Cyprus museum and two marble sculptured sarcophagi in

Cyprus. The most important of the types of coin struck in the island is that with the Aphrodite temple on the reverse.

**Archaeological Exploration.**—This began before the British occupation (T. B. Sandwith, R. H. Lang, L. P. di Cesnola), but it was after the occupation that systematic work was started (under the Cyprus Exploration fund and by O. Richter). In the early part of the 20th century Sir J. L. Myres and M. Markides carried out excavations for the Cyprus museum, and later the Swedish Cyprus expedition devoted several years (1927–31) to the exploration of many sites. The Cyprus museum and (from 1935) the department of antiquities investigated many prehistoric and later sites, while expeditions sponsored by the Pennsylvania university museum, the British School at Athens and the Louvre museum, Paris, explored Bronze Age cemeteries and townsites. After 1950 the British excavated sites at Myrtou and at Kouklia (Palaipaphos) and Swedish and French missions undertook excavations at Kalopsidea, Ayios Iakovos and Enkomi. The department of antiquities conducted large-scale excavations at Salamis. (P. Ds.)

**2. Medieval Period.**—After the division of the Roman empire (A.D. 395), Cyprus remained subject to the eastern emperors, with brief intervals, for more than 700 years. During the 5th century it formed part of the diocese of the orient, under the *comes Orientis*, whose seat was at Antioch. This subordination was probably the basis of the claims advanced by the patriarch of Antioch to appoint and consecrate the metropolitan of Cyprus. These claims were successfully resisted by the Cypriot hierarchy. Both the Council of Ephesus in 431 and the Trullan council in 692 recognized the autocephaly of the Cypriot church and its right to elect and consecrate its own archbishop and bishops.

The island seems to have enjoyed a peaceful existence until the Muslims began their attacks during the 7th century. The first was launched during the years 647–649, when Mu'awiya, amir of Syria, overran Cyprus and laid it under tribute. In 653 it was attacked again, and an Arab garrison was established there. This was withdrawn after 680, and for nearly 300 years Cyprus was to be neither under the full control of Islam nor of Constantinople. Each used Cyprus as a springboard for attacks on the other. The Byzantine fleet prevented permanent Muslim occupation; but their raids were frequent and sometimes prolonged, and it was not until 965 that the emperor Nicephorus II Phocas was able to deliver the island from the constantly renewed attacks. For the next 200 years it remained an integral part of the Byzantine empire. As an outlying province, it was not infrequently used as the base for revolt against the imperial government. From about 1185 Isaac Comnenus, an ambitious Byzantine governor, held it against two successive emperors, his kinsman Andronicus I and Isaac II Angelus; but in 1191 he showed hostility to the English crusaders led by King Richard I, who promptly conquered the island. Richard first sold his conquest to the Knights Templars and then, as they could not pay, bestowed it on Guy de Lusignan, the dispossessed king of Jerusalem.

Guy founded a feudal monarchy in Cyprus which survived until the end of the middle ages. Much of its recorded history during that period concerns the life of the court and of the territorial aristocracy, which, in contrast to the peasantry, was French in speech and culture. Because of the island's trade, however, Italian merchants, especially those of Genoa and Venice, assumed an ever increasing economic and political control until, in the 15th century, Cyprus became part of the Venetian empire.

The kings of Cyprus kept alive the crusading idea. Some, such as Amalric II (1194–1205) and Hugh III (1267–84), were also kings of Jerusalem, but they were unable either to impose unity on the warring factions which weakened the Syrian kingdom, or to prevent its extinction in 1291 by the Mamelukes of Egypt. Even then, Cyprus remained a base for counterattack against the Muslims. Hugh IV (1324–59) formed an alliance with the papacy, Venice and the Knights Hospitallers of Rhodes, and in 1344 an expedition fitted out by this league retook Smyrna (Izmir) from the Turks. His son Peter I (1359–69) devoted himself to the organization of a crusade. In 1361 he took Gorigos (Korykos) and Adalia (Antalya) in Asia Minor. In 1362 he recruited an army and fleet in western Europe, and took Alexandria (Oct. 10, 1365).

But he could neither retain the conquest nor persuade the rulers of western Europe to equip another crusade.

After Peter's assassination in 1369 the fortunes of the royal house declined, while those of the Italian republics rose to new heights. The economic activity in Cyprus was a result not only of its own silks, sugar and salt but also of its importance as an entrepôt for the eastern trade, especially after the Christians lost the Syrian ports. All the important commercial communities of the Mediterranean therefore established stations and bought trading privileges in Cyprus. In 1373 the Genoese took advantage of the local political situation to acquire complete control of Famagusta, the principal port, and were able to dominate trading and government in the island for 90 years. In 1426 an expedition launched from Egypt overran the island, and for a generation its kings were nominally the tributaries of Cairo.

The situation was redeemed by King James II (1460–73), a bastard of the royal house who in his father's lifetime had become archbishop of Nicosia. With the help of a Muslim force from Egypt he seized power in Cyprus and expelled the Genoese from Famagusta (1464). In 1472 he allied himself to Venice by marrying Caterina Cornaro (*q.v.*). On his death Cyprus was ruled from Venice in the queen's name till in 1489 the republic caused her abdication; the island remained a Venetian possession until its conquest by the Ottoman Turks in 1570–71. (R. C. SMA.)

**Medieval Relics.**—From the period between the peace of the church and the devastating Arab raids of the mid-7th century there survive numerous remains of basilican churches, a damaged apse

mosaic at Lythrangomi comparable to those of the 6th century at Ravenna, Italy, a bath complex at Curium with fine mosaic pavements, and a treasure from the site of the ancient Lapithos consisting of gold ornaments and silver plate. Wall paintings of Byzantine and later styles exist in churches still in use, some domed in the Byzantine fashion, some wood roofed and tiled. Outstanding monuments of the Latin kingdom are the Gothic cathedrals of Nicosia and Famagusta, now used as mosques, and the abbey of Bellapais. Of military architecture, Byzantine, Frankish and Venetian, a good deal remains, foremost among it the walled city of Famagusta. (X.)

**3. Turkish Rule.**—On March 7, 1573, Venice recognized the sultan's sovereignty over Cyprus. The period of Turkish administration lasted for 300 years. At first comparatively enlightened (serfdom was abolished, the Orthodox archbishopric restored, and the Christian population granted a large measure of autonomy), it became neglectful and often oppressive. There were serious risings in 1764, 1804, and 1821. In 1838–39 and 1856 attempts were made to introduce reforms and some self-government with a local divan (council). The reform movements lagged, however, and there were few internal improvements since the imperial treasury retained most of the island's income. In the courts, Christian testimony was seldom honoured.

**4. British Administration.**—On June 4, 1878, Great Britain took over the administration of Cyprus and occupied it by agreement with the sultan, who was thereby assured of British help if the Russians attacked Turkey's eastern provinces. Cyprus remained under Turkish sovereignty, but from the start elements of the Greek population (80% of the total) asked the British to grant *enosis* (union with Greece). For many years this demand was of little more than academic significance.

Cyprus was annexed to the British crown in November 1914, when war with Turkey broke out. The British government offered the island to Greece 12 months later, if Greece helped Serbia, then invaded by Bulgaria. Greece refused to help Serbia, and the offer lapsed. Turkey formally recognized the British annexation under the Treaty of Lausanne, ratified in 1924; and in the following year Cyprus was made a crown colony.

In 1931 serious disturbances arose out of the demand put forward by sections of the Greek population for *enosis*. The Legislative Council was abolished and power to legislate was vested in the governor alone.

During World War II, pack transport, pioneer, motor transport, and other units were raised in Cyprus by voluntary enlistment. They served in France, the Middle East, Greece, and Italy. Apart from a limited number of air raids, Cyprus remained immune from enemy attack throughout the war.

After the war agitation for *enosis* was resumed. Archbishop Makarios III (q.v.), patriarch of the Orthodox Church in Cyprus, emerged as the leader of the movement, with the support of various political groups. The campaign for *enosis* grew more violent, with persistent attempts to smuggle arms from abroad, and nationalists in metropolitan Greece raised their voices in encouragement of the malcontents. This provoked extremes of resentment in Turkey. At the London Conference in September 1955 the British, Greek, and Turkish foreign ministers failed to agree on a solution, and an atmosphere of terrorism, repression, and mistrust prevailed. In this the lead was taken by EOKA (Ethniki Organosis Kypriakou Agonos, "National Organization of Cypriot Struggle") headed by Col. Georgios Grivas ("Digenes" or "Dighenis"), formerly an officer in the Greek Army. The organization enjoyed wide support in the Greek Cypriot community and included a guerrilla body which carried out terrorist attacks on British servicemen and establishments. British reinforcements were sent to the island to suppress the guerrillas, and in the autumn of 1955 Field Marshal Sir John Harding was appointed governor. Emergency regulations were introduced. Negotiations opened with Makarios, the main issue being self-determination which the British government was not willing to concede at that time although ready to grant a large measure of self-government.

In March 1956 Makarios and the bishop of Kyrenia were deported to the Seychelles. For a year terrorism raged throughout

Cyprus, but all attempts to suppress EOKA failed. In the meantime Lord Radcliffe had been asked to advise on a new liberal constitution. His proposals, published in December 1956, were accepted by the British government. On March 14, 1957, EOKA offered to suspend its activities if Makarios was released from exile. A few days later he was freed and permitted to go where he liked except to Cyprus. Terrorist activities ceased, and many of the restrictions were lifted, but in such an atmosphere progress toward a settlement was slow. Sir John Harding was succeeded in December 1957 by Sir Hugh Foot. By this time the Turkish Cypriot community (about 17.5% of the island's population), led by Fazıl Küçük, was thoroughly aroused at the prospect of *enosis*, and put forward the demand that the island should be partitioned. Renewed efforts in 1958 by the British government and by NATO to produce a settlement came to nothing in face of the Greek community's desire for union with Greece, and the Turkish for partition. Terrorism broke out again and fresh restrictions had to be imposed. But in the autumn of that year the archbishop proposed that after a fixed period of self-government Cyprus should become an independent state.

This suggestion eventually led to negotiations between the Greek and Turkish governments and to a conference held in Zürich, Switz., in February 1959, at which the British were not represented. The conference reached agreement in principle. The solution arrived at in Zürich was immediately approved by the British government. British sovereignty was to be retained over the two military bases at Dhekelia and Akrotiri, in all an area of 99 sq.mi. (256.4 sq.km.). The new republic would not participate in a political or economic union with any other state, nor would it be subject to partition. Greece, Turkey, and the United Kingdom guaranteed the independence, integrity, and security of the republic, and Greece and Turkey undertook to respect the integrity of the areas remaining under British sovereignty. Executive power was vested in a Greek Cypriot president and a Turkish Cypriot vice-president, to which posts Makarios and Küçük had previously been elected. They would have a council of ministers comprising seven Greeks and three Turkish Cypriots. It was later agreed that the decisions of the council would be binding on the president and vice-president, who could, however, impose a veto in matters relating to security, defense, and foreign affairs. There would also be a House of Representatives elected for five years consisting of 50 members, of whom 70% were to be elected from the Greek and 30% from the Turkish Cypriot communities, and the civil service was to consist of 70% Greek and 30% Turkish Cypriots. A Turco-Greek military headquarters was to be set up in the island to train the Cypriot Army.

**5. Republic of Cyprus.**—The first general election took place on July 31, 1960. Of the 35 seats allotted to the Greek Cypriots 30 were won by supporters of the archbishop, 5 by agreement being allotted to AKEL (Anorthotikon Komma Ergazomenou Laou), the Cypriot Communist Party. All 15 seats allotted to the Turkish Cypriots were won by supporters of Küçük. The republic came into being on Aug. 16, 1960, and Cyprus was admitted as a member of the United Nations shortly afterward. It remained a member of the sterling area, and the British government agreed to make £12,000,000 of financial assistance available, payable over five years. Cyprus was admitted to membership in the Commonwealth of Nations in March 1961.

Difficulties soon arose between the Greek and Turkish communities, and by the autumn of 1963 the constitution had become unworkable. Over Christmas there was a widespread outbreak of rioting in which British troops tried to keep order. In March 1964 the UN Security Council agreed to send to Cyprus a mixed force (UNFICYP, the United Nations peacekeeping force in Cyprus). To a great extent this force secured the cessation of fighting between the two communities. There were, however, further outbreaks during August 1964 in the northwest of the island, when Turkish government aircraft bombed Greek Cypriot villages to repel a Greek Cypriot offensive in the area; and again during November 1965 at Famagusta. Because of the disturbances, by the summer of 1964 many Turkish Cypriots had left their homes and had concentrated in the districts north and west of Nicosia;

the Turkish Cypriot delegates boycotted the House of Representatives, and the government of the island was carried on in effect by the Greek Cypriot majority. The latter extended the tenure of office of President Makarios by one year in July 1966, and the Turkish Cypriot delegates shortly afterward extended that of Vice-President Küçük by the same period. Attempts by representatives of the UN to mediate had successively ended in failure, as had those of the U.S. and of the Greek and Turkish governments. The mandate of UNFICYP was renewed for a period of six months in December 1966 (as on several previous occasions).

Meanwhile the Greek Cypriot administration prepared itself against the imposition of *enosis* by ordering arms from Eastern Europe, notably Czechoslovakia. As far back as January 1965 Andrei Gromyko, the Soviet foreign minister, had indicated that he was in favour of a Turkish proposal that a solution of the problem might be found in a federal, but sovereign and united, Cyprus. (B. S.-E.)

### III. POPULATION AND ADMINISTRATION

The population at the 1960 census was 577,615, which showed an average annual increase of very nearly 2% since the previous census in 1946. A high birth rate (26 per 1,000) and a low death rate (6 per 1,000) accounted for the increase. Emigration amounts on average to 6,000 persons a year, though in 1960 and 1961 it was more than double that figure. The census of 1960 gave the following composition of the population: Greek Cypriots 77.71%; Turkish Cypriots 18.07%; the rest was made up by Maronites, Armenians, Britons, and others. The Greek Cypriots are members of the Autocephalous Church of Cyprus, an independent Greek Orthodox Church (*see* CYPRUS, CHURCH OF). The Turkish Cypriots are Muslims. About two-fifths of the population live in the six district capitals: Nicosia, Famagusta, Larnaca, Limassol (*qq.v.*), Kyrenia, and Paphos. Greater Nicosia, the capital of the island with 95,343 persons, accounts for about half of that. The rural population lives in 627 compact and nucleated villages; some of these villages are rapidly becoming dormitory centres for urban workers, miners, and other nonagricultural labourers.

About half the total population is gainfully employed and about 40% of these are engaged in agriculture, the other large categories being manufacture and construction, commerce, transport, and other related activities. Mining and quarrying engage just over 2%. The large number (about a quarter of the total employed) in manufacture and construction is the result of the amount of building that has been done since 1950. Trade unions are active and there were 179 unions with a total membership of about 64,800 in 1962.

The Zürich Agreement of 1959 (*see* *History* above) laid down the basic provisions for the creation and administration of the new state of Cyprus. The constitution makes elaborate provisions, among other things, for a balancing of interests of the Greek and Turkish communities and for offering safeguards for the Turkish minority.

The Cyprus system of government is a presidential one: The president must be a Greek Cypriot while the vice-president is a Turkish Cypriot. Certain important functions and prerogatives are exercised separately or jointly by the two. The cabinet of ten is appointed, the president proposing the seven Greek ministers and the vice-president the three Turkish ministers. Proportions of 7:3 (except in the army where the proportion is 6:4) were expected to be established in the public service and other state organizations.

There is a Constitutional Court and a High Court, each of which is presided over by a neutral, non-Cypriot person. Legislative functions are vested in two chambers: the House of Representatives, which is composed of both Greek and Turkish Cypriots numbering 35 and 15 respectively; and the two communal chambers, one Greek and the other Turkish Cypriot. The communal chambers deal with the religious, educational, cultural, and social matters of their respective communities. In 1964-65 certain constitutional and administrative changes were introduced pending a solution of the "Cyprus problem" (*see* *History*, above). Greek

EMIL BRUNNER PIX FROM PUBLIX

and Turkish are the official languages but in addition English is spoken and widely understood.

Under the London Agreement the United Kingdom has retained sovereign rights over areas totaling less than 100 sq.mi. (160 sq.km.). They are used as bases and are administered by the Air Ministry. In certain matters mixed administration (British and Cypriot) operates in the base areas.

The structure of the district and village administration remains largely as it was under British rule; *i.e.*, management by village commission, but there are provisions for separate (Greek and Turkish) elected municipalities for the five largest towns: Nicosia, Limassol, Famagusta, Larnaca and Paphos.

Since Cyprus was freed from malaria in 1949 it has become a healthy island and no quarantinable diseases occur. There are general hospitals in the six main towns but only 11 small hospitals in rural areas. In addition two military hospitals exist in the base areas. Two mining companies keep private hospitals. Private medical practice is very extensive but its services are expensive. In 1963 there was one doctor per 1,370 persons, and 70 private hospitals were functioning.

Literacy in Cyprus has improved considerably since World War II. Illiterates are found among old people, especially women (in 1960 illiterates comprised 18.1% of the population, nearly 80% in the over-40 age group), although in the absence of compulsory education some younger people may remain near illiterate. Elementary school education is free but not compulsory for children of 6 to 13. Vocational education is carried out in eight technical schools, including rural schools, where the emphasis is on agriculture, and the Forestry College at Prodromos which caters to overseas students also. Postsecondary education is limited to two teachers' training colleges, one for the Greek and one for the Turkish community. Education is the responsibility of the two communal chambers and is carried out separately and independently.

A social insurance scheme, introduced in 1957, provides cash benefits for marriage, maternity, sickness, unemployment, widowhood, orphanhood, old age, and death. It compulsorily covers all employees except agricultural workers on small farms.

## IV. THE ECONOMY

**1. Agriculture and Industry.**—Agriculture is the main source of employment and the basic industry, contributing a little more than one-fifth of the gross national production. It is a saturated industry carried out by peasants working on an average holding of  $15\frac{1}{2}$  ac. dispersed over 10 scattered plots. A low and erratic rainfall and the acute shortage of irrigation water reduces the productivity of the land. Thus in agriculture very low incomes and underemployment are prevalent. About 60% of the area of Cyprus is in agricultural use, but only 5% of the agricultural land is irrigable during the hot summer, so that only one crop a year is possible over most of the land; but, what is more, the extensive fallow system (covering about 33% of the cultivated land) condemns large areas to one crop every two years. Despite these setbacks a wide variety of crops are produced. The main cultivable area lies in the central and coastal lowlands but steep slopes are also cultivated.

Cereals account for approximately one-third of the agricultural land but Cyprus does not cover its needs in wheat or feeding stuffs; vines cover 8% of the cultivated area; and a large variety of crops and vegetables account for the rest of the land. The main crops other than cereals are pulses, legumes, cotton, sesame, tobacco; vegetables include potatoes, carrots, cauliflowers, tomatoes; melons and watermelons are also grown extensively. Citrus fruits are the most valuable and contribute the largest single item to agricultural exports. Carobs, olives, and almonds are plentiful. Apples and cherries are important in the massif. The low rainfall and the summer drought do not permit the growth of pastures worth the name and the island's flocks of sheep and goats subsist on rough pasturage and stubble and need hand-feeding in periods of scarcity. The dairy cattle are exclusively stall-fed. Sheep and goats are milked and provide the bulk of dairy products. Cyprus does not cover its needs in meat or dairy produce. Mules, donkeys, pigs, and poultry are widely kept.

Forested land covers 669 sq.mi. (1,733 km.), or 18.7%, of Cyprus but only one-fifth of that area is fully stocked. All forest land, with the exception of 52 sq.mi. of privately owned forest, is state owned. Timber yields supply only a very small fraction

of the island's needs. Except for a few motor trawlers, fishing is from small boats. Fish is a luxury food in Cyprus. Sponges of good quality are obtained in Cyprus waters by non-Cypriot fishers.

**Mining and Industry.**—Copper and the name of Cyprus are related. The Roman *aes cyprum* ("ore of Cyprus") was corrupted to *cuprum* from which was derived the Anglo-Saxon *coper*. Copper was mined from the end of the 3rd millennium B.C. to Roman times. Modern mining dates from World War I. Cupreous and iron pyrites are now the most important minerals mined in the island. Other minerals include asbestos, chromite, gypsum, and amber. Apart from flotation treatment of the copper ores, the minerals are all exported almost raw. The value of minerals exported in the early 1960s fell well below half the value of all exports (the peak export value was in 1956, the decline being due to the drop in prices).

Cyprus, having no fuel of its own and no important source of energy other than unutilized sunshine, relies for power on thermal electricity on the basis of imported oil. The central generating station, with an output of almost 300,000,000 units, is located at Dhekelia.

Only about 12.5% of the gross domestic production is contributed by industry. Many industrial establishments are scarcely more than minor cottage industries and only about 3% employ more than ten persons. Important industries include wines and spirits and soft drink manufacture, brewing, flour milling, cigarette making, cement manufacture, and canning. All the output is for home consumption, except for wines and spirits, of which a considerable quantity is exported. Besides the shortage of water the island lacks three things: fuel, any large output of raw material except minerals, and a ready market.

**2. Trade and Communications.**—The value of exports in the early 1960s averaged £20,000,000 annually while imports exceeded £47,000,000. Imports include manufactured goods (vehicles, machinery, electric goods, fabrics, fuel) and also food (wheat, vegetables, fish, oils, meat, and dairy products) and feeding stuffs. Exports include minerals, citrus fruit, carobs, potatoes, vegetables, fruit, and wines and spirits. More than one-third of the imports

and more than two-fifths of the exports came from or went to the United Kingdom.

Employment in communications in the early 1960s was about 4% of the labour force. The main seaports are Famagusta, where vessels of an overall length of 425 ft. and less and with a draft of 22 ft. 6 in. can berth alongside the quay, and Limassol and Larnaca which are open roadsteads. Considerable developments and improvements had been made in all ports and a new harbour was completed at Famagusta in 1965. Shipping entered and cleared at Cyprus ports exceeded 4,500,000 registered tons net.

The only airport in Cyprus permanently open to international traffic is at Nicosia. Links are mainly with Europe, the Middle East, Africa, and the Far East.

There are 3,875 mi. (6,236 km.) of roads on Cyprus, about 1,500 (2,400) of which are asphalted. The total number of vehicles exceeded 63,000 in the early 1960s, more than half of which were private cars.

The six main towns and about 35% of the villages are connected

by telephone, while the forest service has its own network. The inland telegraph system connects the main towns and larger villages which accept both overseas and inland telegrams. The radio-telephone service is available to the United Kingdom, most European countries, North America, Cuba, Mexico, the U.S.S.R., Australia, Kenya, Turkey, Israel, U.A.R., and other Arab countries.

A broadcasting service and a television service with Greek, Turkish, and English programs are in operation.

**3. Finance.**—The monetary unit is the pound sterling which equals 1,000 mils. Cyprus announced in 1959 that it would stay in the sterling area for a minimum of ten years.

After World War II there were two ten-year development plans, or rather budgetary arrangements, the one lasting its full course (1946–56) and the other hardly implemented. A UN economic survey team arrived in Cyprus in 1960 to study the possibilities of economic development of the island as a guide to development expenditure and economic planning with a view also to utilizing expected foreign aid.

In 1961 the government announced a five-year development plan envisaging the investment of £43,000,000, in order to finance water conservation, the improvement of agricultural production, the expansion of electrification and of existing industries, the promotion of the tourist industry, the improvement of docks and harbours, especially at Famagusta and Limassol, the expansion of public health facilities, and the establishment of a geological survey department. In 1963 the development plans were revised, the aim being to achieve an annual growth rate of 5–6%, and proposed investment from both public and private sectors was about £118,000,000.

Current history and statistics are summarized annually in *Britannica Book of the Year*.

**CYPRUS, CHURCH OF**, is one of the oldest autocephalous Orthodox churches, and, as such, a member of the Orthodox Eastern Church (*q.v.*). Its independence, first recognized by the third ecumenical Council of Ephesus (431) against the claims of the patriarch of Antioch, was ratified by the emperor Zeno (474–491) on the basis of the argument provided by the alleged body of the church's reputed founder, St. Barnabas (*q.v.*; Acts xv, 39), discovered at Salamis in 488. Under Zeno several privileges were granted to the archbishop of Cyprus. The independence of the Church of Cyprus, again reasserted by the Trullan council (692), was never lost, not even during the occupation of the island by the crusaders. Under the Lusignans and the Venetians (1193–1571), the efforts of the Latin bishops to submit the Orthodox Church of Cyprus to the pope's authority were unsuccessful. With the conquest of the island by the Turks, the Latin hierarchy and the pressure exercised by it disappeared. Under Turkish rule, the Church of Cyprus was exposed to the hazards familiar to all the other Greek churches during this period. It was granted the same rights as the patriarchate of Constantinople, and its archbishop moreover was recognized as the ethnarch of the subjugated Greek people of the island. The highest ecclesiastical authority lay with the synod, composed of the archbishop of Nicosia and the three other bishops of the island (Paphos, Citium or Kition and Kyrenia or Cyrenia), who were, and still are, elected by both clergy and laity, each of the four bishoprics being divided into several parishes. The bishops were recognized as the leaders of the nation and hence were held responsible to the conqueror. At

the time of the Greek national war of independence (1821) all the bishops on the island, as well as several abbots and some eminent Greek citizens, were hanged by the Turks. During the British occupation of the island, beginning in 1878 and continuing from 1925, when Cyprus was given the status of a colony, until 1958, the position of the bishops as leaders of the nation was not changed. This is why the bishops with the archbishop at their head took an active lead in the movement of their people for *enosis* (*i.e.*, union with Greece). In 1956 the archbishop, Makarios, and the bishop of Kyrenia were exiled by the British. When in 1960, after the fierce struggle for *enosis*, the new Cypriot republic became independent, the church was assured of its position as an autocephalous and independent Greek Orthodox Church on the basis of its old titles. The archbishop became the first president of the new republic. See also CYPRUS.

**CYPSELUS**, tyrant of Corinth from about 657 to 627 B.C., was the son of Aeëtion and Labda, a member of the ruling family, the Bacchiadae. He is said to have derived his name from the fact that when the Bacchiadae, warned that he would prove their ruin, sent emissaries to kill him in his cradle, his mother saved him by concealing him in a chest (*cypsele*). By courting popular favour Cypselus drove out the Bacchiadae and made himself master of Corinth. Herodotus, prejudiced against tyrants, said he ruled harshly, but he is generally represented as beneficent and popular. He pursued an energetic commercial and colonial policy: he founded the colonies of Leucas, Anactorium and Ambracia.

Cypselus spent large sums on buildings and works of art. At the same time he strove by his dedications to gain the good will of the powerful priesthoods of Delphi and Olympia. He was succeeded by his son Periander (*q.v.*). See CORINTH: History.

**CYRANO DE BERGERAC, SAVINIEN** (1619–1655), French writer, around whose name a number of unhistorical legends have accumulated, was born in Paris, March 6, 1619. Adopting the military profession, he fought at Mouzon and at Arras, but, twice wounded, had to retire from the army. He then turned to philosophy and took up residence in the Collège de Lisieux in Paris. He probably knew Pierre Gassendi and, certainly, La Mothe Le Vayer. He died in Paris, July 28, 1655.

Cyrano's writings fall into several groups. As a political writer, he was the author of a violent pamphlet against the men of the Fronde, in which he defended Mazarin in the name of political realism as exemplified in the tradition of Machiavelli. As a dramatist he wrote *Le Pédant joué* (probably 1645) and *La Mort d'Agrippine* (pub. 1654). As long as classicism was the established taste, *Le Pédant joué*, a colossal piece of fooling, was despised; but its liveliness appeals to modern readers as it did to Molière, who based two scenes of *Les Fourberies de Scapin* on it. *La Mort d'Agrippine* is intellectually impressive because of its daring ideas; and the direct and impassioned character of the tragic dialogue makes it interesting theatrically. Cyrano's *Lettres* show him as a master of baroque prose, marked by the boldness and originality of his metaphors. His contemporaries regarded them as absurdly farfetched, but they came to be esteemed in the 20th century as examples of the baroque style.

Cyrano also wrote two novels of imaginary travel, the *États et empires de la Lune* (1657) and the *Histoire comique des états du Soleil* (1662); the former had been expurgated before publication, so that the real text remained long unknown. In these tales Cyrano was inspired by the work and thought of John Wilkins and Francis Godwin; but he added the kernel of his own philosophy, a compound of Italian pantheistic naturalism, Cartesian rationalism and empiricism as preached by Gassendi.

Edmond Rostand's play, *Cyrano de Bergerac* (1897), made Cyrano's name famous, but aggravated the errors committed by the romantics in emphasizing only the more extravagant aspects of his life and work.

The best text of the novels is in the edition of Cyrano's works by F.

Lachèvre (1920–21). See further A. Adam, *Histoire de la littérature française*, vol. II, pp. 113–118 and 146–148 (1948–56). (Az. A.)

**CYRENAICA** (BARQAH), the easternmost part and (until 1963) a province of the united kingdom of Libya, covers an area of 330,258 sq.mi. Pop. (1954) 291,236; (1963 est.) 350,024.

**Physical Features.**—Topographically Cyrenaica comprises: (1) a coastal zone of irregular uplands—Al Jabal al Akhdar of just under 3,000 ft. and the associated cuesta formation of the ancient Marmarican hills immediately to the east, which attain 1,000–1,200 ft.; (2) a lowland zone aligned east-northeastward from the Gulf of Sirte (Khalij Surt), and occupied by a number of oases and salt basins and marshes, where there are to be found marine flora and fauna. Because of this it has been suggested that the lowland zone recently formed an arm of the sea, isolating the coastal zone, but this view is largely discounted; (3) the southern desert: an area of loose sand and stony outcrops, with several oasis groups of which Jalu and Al Kufrah, each comprising several districts, are the most important. The Sand sea of Calanscio lies south and east, presenting a formidable barrier to movement eastward. Only two routes across are known.

Because of its elevation and seaward aspect, Al Jabal al Akhdar has a heavier and slightly less erratic annual rainfall, which attains 15–20 in. on the crest. This gives rise to an area of natural scrub woodland, unique in Libya—low juniper and lentisk trees with occasional wild olives, Mediterranean pines and evergreens. Elsewhere on the uplands a terra rossa soil occurs sporadically allowing cultivation, the largest of these areas being the plain of Barca (Al Marj). Away from the higher parts of Al Jabal al Akhdar (green mountain) vegetation degenerates into thin steppe and semidesert forms, with the Marmarican hills distinctly drier and barer than the northwest. (W. B. Fr.)

**History.**—The northern half of the ancient district of Cyrenaica was known as the Pentapolis from its possession of five considerable cities, viz., Euesperides-Berenice (Bengasi), Barca (Al Marj), Cyrene (q.v.; Shahhat), Apollonia (Marsa Susah) and Teuchira-Arsinoe (Tukrah). These cities were founded by Greek colonists, Cyrene, the earliest, being established c. 630 B.C. In later times two more towns rose to importance: Ptolemais (Tulmaythah) and Darnis-Zarine (Derna). These all lay on the coast with the exception of Barca and Cyrene, which were situated on the highland now called Al Jabal al Akhdar, a few miles inland.

Under the Ptolemies the inland cities declined, and Cyrenaica began to feel the commercial competition of Egypt and Carthage, from which easier roads led into the continent. When all north Africa passed to Rome, and Cyrenaica itself, bequeathed by Apion, the last Ptolemaic sovereign, had become a Roman province in combination with Crete (67 B.C.), this competition told more severely; the Greek colonists, grown weaker, found themselves less able to hold their own against the Libyan population. A great revolt of the Jewish settlers (A.D. 115–116) did much damage to Cyrene and Barca. Ptolemais became the local capital in 297 and in the 6th century Apollonia was the seat of the governor. After Arab armies under the leadership of Amr ibn al-As had conquered the country in 642, inland Cyrenaica regained importance, lying as it did on the direct route between Alexandria and Kairouan; and Barca became its chief centre. (For archaeology of the region see AFRICA: Archaeology: Carthaginian and Classical.) But when the Ottoman empire superseded the Arab, resulting in the virtual independence of both Egypt and Tripoli, the district between them relapsed to anarchy, which continued after Mahmud II had resumed direct control over Tripoli (1835), and by the mid-19th century Cyrenaica was still so free of the Turks that Sheikh Mohammed bin 'Ali al-Sanusi chose it as the headquarters of his nascent fraternity (see SENUSI).

Cyrenaica, with Tripolitania, was ceded to Italy in 1912 as a result of the Italo-Turkish War (q.v.), but in Cyrenaica at that time and until after World War I the Italians occupied only the coastal towns of Bengasi, Derna and Tobruk. In 1920 by the agreement of Ar Rajmah (Regima) they conferred the title of amir on the Senusi leader Mohammed Idris (later King Idris I; q.v.) as head of an autonomous administration over the Bedouins and the oases. The Italian Fascist government, however,

rejected this agreement and after wearing down Bedouin guerrilla resistance inaugurated a scheme to relieve the overpopulation of Italy by the mass colonization of Al Jabal al Akhdar. In 1940 about 50,000 Italian peasant colonists were busily converting northern Cyrenaica (Italian Cirenaica) into the semblance of an Italian province, cultivating cereals, vines and fruit trees. Meanwhile, on Jan. 9, 1939, Cyrenaica and Tripolitania were incorporated into the metropolitan kingdom of Italy. Cyrenaica became a major theatre of operations during World War II and the Senusi leaders with a Libyan Arab force gave useful service to the British during the desert campaigns of 1940–42. The Bedouins of Cyrenaica also co-operated freely with the British. When the British finally occupied Cyrenaica after the victory (Oct. 1942) at El Alamein (Al 'Alamayn) the Italian colonists had been evacuated and the population was once again 98% Muslim and Arabic-speaking.

After World War II the inability of the great powers to agree on the future of the former Italian colonies protracted the British military administration of Cyrenaica and although Mohammed Idris was again accorded the title of amir in 1946 it was not until 1951 that he was recognized as king of the united kingdom of Libya. As a result of a 20-year treaty of friendship signed with Libya in 1953 the British government was empowered to maintain certain defense establishments in Cyrenaica (see also LIBYA; WORLD WAR II).

**Economy.**—Animal husbandry is the chief occupation of Cyrenaica, but this is usually combined with some degree of cultivation. A frequent pattern is to sow a number of very small plots at different altitudes and in different localities during the seasonal routine of animal movement. Barley (being a native) in particular will thrive with little or no attention, and can be harvested on return. In better watered areas cultivation is more regular, especially round Bengasi, Derna, Barca and Marsa Susah. In the southern oases millet, dates and vegetables are staples, but in the north conditions are too cool and damp for luxuriant date growth. Most animal herding involves a certain degree of nomadism, local on Al Jabal al Akhdar but more extensive toward the south, with the Jabal used as summer quarters; here the scrub provides grazing at most seasons.

Other activities are on a small scale: a very few processing industries and the sale of live animals and animal products, for which there are markets in Egypt, Malta, and Greece. The southern oases have few economic contacts with the north. Tomatoes ripen early in the Aujila (Awjilah) and Jalu oases and can sometimes be sold, even abroad; but since the decline of overland routes into central Africa (with the slave trade once a significant factor) the importance of the oases has declined.

**Communications.**—The chief towns, with population figures given in the 1964 census, are as follows: Bengasi (137,295), Derna (21,432), Tobruk (15,867) (qq.v.), Ajdabiyah (15,430), and Barca (10,645). Bengasi has a moderately good harbour and lies on an extensive plain with supplies of underground water. The other towns are mainly regional markets and route centres with some local agriculture. All lie on one main line of communication: the east-west coastal road linking Tunis-Algiers and Egypt. This is well maintained and follows the coast except in the Bengasi-Derna sector. There are two airfields: at Benina (Baninah) for Bengasi and at El Adem (B'r al 'Uzaym) for Tobruk, and the oases are reached by tracks.

**CYRENAICS**, a Greek school of philosophers, so called because Cyrene in north Africa was the centre of its activity and the birthplace of several of its members. Although the elder Aristippus (q.v.), a pupil of Socrates, was generally recognized as the founder, its known adherents were contemporaries or successors of his grandson and namesake, and its doctrines are very inadequately recorded in a form that suggests a later compilation, probably the end of the 4th century B.C. Yet the combination of sophistic and Socratic elements that they offer is compatible with an earlier origin and suits what is known of the elder Aristippus. According to the Cyrenaics, a man knows that things external to

himself exist because they have an effect upon him, but he can know nothing about their nature; all that he can perceive is the way in which he is affected by them. How other men are affected is also unknown. The fact that two men give the same name to their experiences is no guarantee of identity. In this situation the only admissible object of action is to ensure that one's own affections are pleasant. The goodness of pleasure is denied only by those whose minds are perverted. The three possible conditions of the human constitution are violent change, gentle change and stability. The first is accompanied by pain, the second by pleasure, the last by neither. Man must avoid the first and seek the second; it is a mistake to suppose, as did the Epicureans, that the third is pleasant or desirable. Moreover, the pleasure to be sought is that of the moment; only present experience can give present pleasure. Happiness, the sum of pleasures, is to be valued only because it includes momentary pleasures, which are alike in kind, their relative value depending only on their intensity. Bodily pleasures (and pains) are more intense than those of the mind. Nevertheless the latter were recognized and included some that have an altruistic aspect; e.g., joy in one's country's prosperity.

The Socratic contribution to Cyrenaic doctrine is the importance attached to wisdom or insight, as a necessary means to the attainment of pleasures. It has been guessed that, in pursuance of Socrates' suggestion in Plato's *Protagoras*, this insight was employed in a "hedonistic calculus" which balanced pleasures against the previous or subsequent pains that they involved. This is, however, contrary to evidence that both Aristippus and the school held that pains should not be undergone for the sake of future pleasures, since the latter must be problematical. On the other hand, it was said that acts should be avoided that would bring punishment; and it is unlikely that a practical guide to behaviour would recommend every pleasure, on the ground that resulting pains, however probable, fall short of certainty. But the insight needed is wider than this: it can turn circumstances to good account, guard against errors which bring pain (these include those of envy, superstition and falling in love) and enable a man to command pleasures without being their slave. To be stronger than pleasure is a true Socratic ideal and distinguishes the Cyrenaic from the wastrel.

Three Cyrenaics made innovations important enough to give their names to their followers. Theodorus, whose opposition to superstition made him notorious as an "atheist," being anxious to make wisdom sufficient for happiness, denied that pleasures and pains were good or bad; mental cheerfulness, the gift of wisdom, became his aim. One need not believe the tale that Hegesias' lectures drove several hearers to suicide. Doubtful, like Theodorus, about the power of wisdom to procure pleasures, he advised a chief concern with avoiding pains; much pain of mind was to be avoided by regarding such things as poverty and riches, slavery and freedom, death and life as matters of indifference. Finally Anniceris (q.v.) revived the original doctrines with some additions.

(F. H. SH.)

**CYRENE**, the original capital of ancient Cyrenaica (q.v.), the site of which is partly occupied by the modern village of Shahhat in Al Jabal al Akhdar, 8 mi. SW of Marsa Susah, a port on the coast of Libya. It was one of the greatest of Greek colonies.

**History.**—As told by Herodotus, the story of Cyrene's foundation is a characteristic mixture of legend and historical tradition (Herodotus iv, 154 *et seq.*). On the advice of the oracle at Delphi a small group of Greek emigrants, driven by famine from the island of Thera (Santorin), set sail for Libya about 630 B.C. The first settlement on the small island of Platea in the Gulf of Bomba was a failure, and after further application to Delphi the colonists moved to Aziris on the mainland, whence shortly afterward they were led by friendly Libyans to the site of Cyrene itself. Here, on the hill to the south of the perennial spring of Cyrene (Kurana), a nature goddess who was later claimed by Greek tradition as the bride of Apollo, they established their settlement.

The leader of the expedition, Battus, became the first king, founding the dynasty of the Battiadae, whose members, named

alternately Battus and Arcesilaus, ruled Cyrene for eight generations. Under Battus II, about 570 B.C., a further influx of Greek colonists disturbed the hitherto friendly course of Libyan relations; and although the Egyptian army sent by Apries to aid the Libyans was defeated, the later history of the Battiadae was one of recurrent dissension among rival domestic factions and between Greeks and Libyans, allayed temporarily under Battus III by the granting of a new constitution, but soon breaking out again and culminating in a successful, though short-lived, Persian invasion about 515 B.C. The dynasty was finally extinguished about 440 B.C.

Though politically troubled, the rule of the Battiadae was a time of expansion and economic prosperity. Apollonia (Marsa Susah), the port of Cyrene, must have been founded soon after Cyrene itself. Barce (Al Marj) followed under Arcesilaus II, and toward the end of the 6th century Euhesperides, the predecessor of Bengasi. The economy was based on grain, stock breeding, and the exploitation of silphium, a wild plant greatly valued for its medicinal properties.

The republic that followed was politically undistinguished and in 322 B.C. Cyrene passed within the orbit of Ptolemaic Egypt. The Ptolemies seem to have paid particular attention to the cities and to the problems of government. A new port to serve the city of Barce was founded at Ptolemais (Tulmaytah); Euhesperides was shifted to a more favourable site, Berenice; and Teuchira (Tukrah) was laid out afresh under the name of Arsinoë. The constitution given to Cyrene by Ptolemy I, a copy of which is preserved in the museum at Cyrene, is a model of its sort. During this period Cyrene was one of the great intellectual centres of the classical world. Its medical school was famous, and among its citizens it numbered the geographer Eratosthenes and the philosophers Carneades and Aristippus, founder of the Cyrenaics (q.v.). The poet Callimachus was a native of Cyrene.

By the will of its last king, Ptolemy Apion, Cyrenaica passed to the Romans in 96 B.C., and after years of neglect was united with Crete to form a senatorial province (67 B.C.), with Cyrene as the local capital, an arrangement which persisted until Diocletian's great administrative reorganization of A.D. 297, when the capital of the new province of Upper Libya was transferred to Ptolemais. Apart from the great Jewish revolt of A.D. 115, which caused untold havoc in Cyrene, the first two centuries of the empire were a period of relative prosperity. Thereafter the history of Cyrene is one of steady decline, due to the increasing insecurity of the desert frontiers, and aggravated by a disastrous earthquake in A.D. 365. Under Justinian it still possessed two fine churches, but much of the population had already deserted it for Apollonia; with the Arab conquest of A.D. 642 city life came to an end. The outstanding personality of this late period is Synesius, an aristocrat of Cyrene, who became bishop of Ptolemais about A.D. 410.

**Archaeology.**—The remains of the city lie along the brow of the highland of Al Jabal al Akhdar at a height of about 1,800 ft. To the south the plateau slopes very gradually toward the interior, a rich grain raising belt; to the north it drops steeply to a strip of level plain and then steeply again to the sea, 6 mi. distant. The site is a spectacular one, with much to remind the colonists of their native land. The original settlement was on the site of the later acropolis, a prominent rounded spur, defended on the west and southwest by a deep, curving ravine, and on the northeast by a shallower valley, from the southern slopes of which gushed the "fountain of Apollo." Later the city spread southeastward along the ridge linking the acropolis to the main plateau, and, later still, northeastward across the valley onto the adjoining hill previously occupied only by isolated temples. The two hills were enclosed within a single defensive wall, 3 mi. long; and in Ptolemaic times the plan was rationalized by the creation of an approximately rectangular grid of major streets. This grid served as a framework for all subsequent development, and with its establishment the centre of gravity shifted gradually eastward, until the formal centre of the Roman town lay at the crossroads at the head of the valley street.

The exploration of the site, undertaken on a large scale between World Wars I and II by Italian archaeologists, and after World War II by the Libyan government aided by British and Italian

experts, covers three main areas: the fountain and sanctuary of Apollo; the upper city; and the centre of the Roman town at the head of the valley street.

The actual fountain was dedicated to the Nymphs. Immediately in front of it a narrow terrace along the foot of the cliffs served the practical needs of the community; and below this, and quite distinct from it, was the broad terrace of the sanctuary proper. This was dominated by the temple of Apollo. The standing columns are those of the latest restoration, after the Jewish revolt, but the podium incorporates much of the original 6th-century building and its 4th-century successor. In front of it stood the great altar, rebuilt in marble in the 4th century B.C., and beside it, to the north, the temple and altar of Artemis, dating back to the late 7th century, rebuilt in the 4th and enlarged by the Romans. Around this central group were numerous secondary shrines, including those of Isis, Hades, Hecate and the Dioscuri; the successive Greek and Roman *propylaea*; a well-preserved Hellenistic fountain; the 4th-century *strategion*, rebuilt under Tiberius and recently restored and reroofed; and numerous votive monuments. At the west end of the sanctuary was the Greek theatre, converted by the Romans into a miniature amphitheatre; and under Trajan (A.D. 98) the whole of the eastern part was taken over to house a grandiose bath building, destroyed by the earthquake of 365 and rebuilt soon after on a slightly different site. Reused in the floors of the later building were a number of important early inscriptions. The famous Venus of Cyrene, now in Rome, was found in the baths; and a colossal statue of Apollo, now in the British museum, was found in the main temple.

The upper city is laid out about the road that runs along the crest southwestward from the acropolis. Apart from its Roman walls and a temple of Isis, the acropolis itself has been barely examined. Outside it, around the monument that marks the traditional site of the grave of the founder, Battus, there grew up the *agora*, a rectangular open space dating in its present form from the Hellenistic period, with extensive Roman modifications. Around it were grouped public buildings, including three *stoas*, the Hellenistic public record office and *prytaneion* and two buildings identified as a gymnasium and the Roman *capitolium*. From the *agora* a broad street, closed at either end by monumental gateways, runs southwestward to join the main cross street of the city. There stands, restored in the 1930s, the Augustan *Caesareum*, a grandiose forum and basilica modeled on the famous *Kaisareion* of Alexandria; in the late 4th century it was converted into a fortress. The temple in the middle is a 2nd-century addition, whence came a fine statue of Dionysus now in the British museum. Along the south side of the street can be seen the remains of a theatre, several small temples, and the so-called "house of Jason Magnus," a large 2nd-century house with fine mosaics and intarsia floors. Across the street was a colossal *stoa*, 400 ft. long, the windows of its façade flanked by busts of Hercules and Hermes. Behind this is a theatrelike building, possibly the Hellenistic assembly hall, and a Byzantine house with 5th-century mosaics.

The valley street was entirely remodeled in Roman times, with a great covered drain and a flanking portico leading to the sanctuary of Apollo. The first building above the modern village of Shahhat is a Roman market, converted into a theatre after the earthquake of 365. Beyond it lay the Roman city centre, still in process of excavation in the early 1960s. In it can be seen three temples, burned by Christian fanatics, and a small 6th-century basilica with the remains of fine mosaics. Still farther up the valley lies the cathedral, a large 5th-century basilica, remodeled and paved with mosaics in the 6th; opening off it is a baptistery. Beyond it again, unexcavated, are the city walls, a group of large vaulted cisterns and the hippodrome. A huge Doric column, recently re-erected, marks the site of the temple of Zeus, a gigantic Doric building of the late 6th century B.C., partly rebuilt under Augustus and overturned by the Jewish rebels in A.D. 115. The outer colonnades were left lying, but the *cella* was rebuilt to house a colossal statue of Zeus, 12 times life-size, probably a copy of the great statue at Olympia. Temple and statue were destroyed by the Christians.

Beyond the walls the cemeteries of Cyrene stretch for miles in

every direction. They include multiple rock-cut tombs with architectural façades; upstanding masonry tombs, both circular and rectangular; and large groups of rock-cut sarcophagi. The earliest tombs, beside the Apollonia road, date back to the 6th century B.C.; the majority are of late classical and Hellenistic date, many of them reused in Roman times.

**CYRIACUS OF ANCONA** (CIRIACO DI FILIPPO PIZZICOLLI) (1391–1452), an early explorer and inquirer into the remains of classical antiquity, was born in Ancona in the Marches department of eastern Italy, and died at Cremona. A merchant by profession, he traveled extensively in Greece, Egypt and the near east, interesting himself in all kinds of historical objects. His Latin and Greek were largely self-taught and his knowledge of these languages uncertain, but he collected copies of hundreds of inscriptions—along with medallions, statuettes, gems, even manuscripts—which he encountered in his travels. The collection itself was dispersed after his death. The inscriptions, presented in six volumes of *Commentaries* deposited in the Sforza library in Pesaro, were destroyed by fire in 1514. Some of his notebooks and copies of them made by friends survive, and have been published in various places.

See E. W. Bodnar, *Cyriacus of Ancona and Athens*, in the Collection Latomus xliii (1960). (J. H. Yo.)

**CYRIL, SAINT, OF ALEXANDRIA** (c. 375–444), patriarch of Alexandria, an Alexandrian Greek who was an Egyptian national leader as well as theologian, and, since 1882, officially in the Roman calendar a doctor of the church. He succeeded his uncle Theophilus in the see of Alexandria in 412. Cyril's character continues to puzzle interpreters. An able and influential theologian, he was at the same time an astute and sometimes unscrupulous politician. He left a considerable mark on the formulation of orthodox theology, yet the victories he won for the power of his see and his particular ideas were more apparent than real.

His episcopate began with conflicts at Alexandria between the bishop and the prefect Orestes. Cyril closed the churches of the Novatians (a schismatic sect that had been tolerated at Constantinople) and began, but apparently did not complete, the expulsion of the Jews. There were victims on each side in the riots that followed, of whom Orestes' friend, the learned Neoplatonist Hypatia (q.v.), is the most famous. Cyril, who at least had not prevented these events, was forced to acknowledge the rights of the civil authority, but remained the leading citizen of Egypt. His most extensive literary production belongs to the following years. Commentaries on selected passages of the Pentateuch, on Isaiah and the Minor Prophets, and on the Gospels of John and Luke have been preserved in whole or in part. His central thought seems to be unity—the unity of the work of God in Old and New Testaments (maintained by a moderate use of allegory), and the unity of God and man in Christ, described at this period in terms of the indwelling of the divine Word in human flesh.

In theology Cyril was in conflict with the more literal school of Antioch, and in church politics was jealous of the rising see of Constantinople. Both causes combined when the Antiochene Nestorius (q.v.) became bishop of Constantinople in 428. Nestorius refused to call the Virgin Mary *Theotokos* ("mother of God") or, literally, "God-bearer". Cyril insisted on the term as expressing the intimate union of the divine and human natures, made one in the incarnation. The letters and treatises of this controversy develop his theology further, recognizing more definitely the fullness of Christ's humanity along with the oneness of his person. To Cyril's anathemas Nestorius replied with counteranathemas, and the dispute was referred to a general council at Ephesus in 431. Armed with a commission to represent Pope Celestine I as well, Cyril convened the council and condemned Nestorius before the oriental bishops arrived, headed by John of Antioch, and condemned Cyril. Lavish gifts to courtiers secured the imperial recognition of Cyril's council, and Nestorius was banished (see COUN-

cul). But the peace of the church was not restored till 433, when Cyril accepted as orthodox an Antiochene statement which emphasized the distinctness of the two natures. In this modified sense Ephesus was accepted as an ecumenical council; Cyril's own position, expressed in the phrase "one nature of the incarnate Word," incorrectly ascribed to Athanasius, was developed by his successors into the more extreme monophysitism condemned at Chalcedon in 451 (see MONOPHYTES). By the time of Cyril's death in 444 the bishops of Constantinople had recovered the prominent position which inevitably belonged to the see of the imperial city.

The chief work of Cyril's more quiet later years was his reply to the emperor Julian the Apostate's *Against the Galilaeans*, the latest work of ancient Christian apologetic against paganism, and of additional interest as preserving considerable extracts from Julian's work. More in tribute to his historic achievements than to his character, Cyril is honoured as a saint (feast day Feb. 9 in the Roman calendar; June 9 in the Greek) and doctor of the church.

**BIBLIOGRAPHY.**—The collected edition of J. Aubert (1638) was reprinted in J. P. Migne, *Patrologia Graeca*, vol. lxxviii-lxxvii; other works were published between 1838 and 1877 by A. Mai and P. E. Pusey, and many of the anti-Nestorian works are included in E. Schwartz, *Acta Conciliorum Oecumenicorum*, vol. i (1922- ). There are partial English translations in the "Oxford Library of the Fathers," and for the Ephesian documents in *Post-Nicene Fathers*, ser. ii, vol. xiv (1900). See also W. Bright in *Dictionary of Christian Biography* (1877); G. L. Prestige, *Fathers and Heretics*, lecture vii (1940); P. Batiffol, "Les présents de saint Cyrille à la cour de Constantinople," in *Études de liturgie et d'archéologie chrétienne*, pp. 154-179 (1919); H. Chadwick, "Eucharist and Christology in the Nestorian Controversy," *Journal of Theological Studies*, new series, ii, pp. 145-164; J. Quasten, *Patrology*, vol. iii, pp. 116-142 (1960); and the histories of dogma by A. von Harnack and J. Tixeront. (E. R. Hy.)

**CYRIL, SAINT, OF JERUSALEM** (c. 315-386), bishop of Jerusalem, his birthplace, fostered the development of the "holy city" as a pilgrimage centre for all Christendom. Though he seems to have had few interests in the absorbing theological controversies of the time, he was none the less distrusted for not being a partisan. Three times exiled from his see by the Arians, he apparently was suspected at the Council of Constantinople (381) by the strictly orthodox for his associations with the "Homoiousians" (moderate Arians).

Cyril's primary surviving work is a collection of 24 catechetical lectures delivered to candidates for baptism. The first 19, based on the Jerusalem baptismal creed, were given during Lent, and the concluding 5 then instructed the newly baptized in the week after Easter. These lectures are characterized by clarity of exposition, abundant use of Scripture and a strong pastoral purpose. The last five throw light on contemporary liturgical practice and sacramental teaching. Cyril's eucharistic theology is an advance on that of earlier writers. He interprets the Lord's presence in terms of transubstantiation and describes the rite in pronounced sacrificial language. The last five lectures have been attributed—without, it would seem, compelling evidence—to Cyril's successor, John. Cyril's feast day is March 18. He was declared a doctor of the church in 1883.

**BIBLIOGRAPHY.**—Editions by A. A. Touttée (1720; reprinted in J. P. Migne, *Patrologia Graeca*, vol. xxx, 1857) and by W. K. Reischl and J. Rupp, 2 vol. (1848-60). Text of Lectures 19-23 with Eng. trans. by R. W. Church and introduction by F. L. Cross (1951). See also W. J. Swaans in *Le Muséon*, 55:1-43 (1942). (F. L. C.)

**CYRIL AND METHODIUS, SAINTS**, "the apostles of the Slavs," two Greek brothers from Thessalonica. They received their title because they not only completed the christianization of the Slavs in the Danubian region but also, at least through their disciples, influenced the religious and cultural development of all Slavic peoples (see SLAVS). Cyril (whose original name was Constantine) was born about 827 and Methodius about 825. Both were outstanding scholars, theologians and linguists. In 860 Constantine, who had already participated in an earlier mission to the Arabs and was professor of philosophy at the patriarchal school in Constantinople, worked along with his elder brother, the abbot of a Greek monastery, for the conversion of the Khazars northeast of the Black sea. In 862 Rostislav, the ruler of the Great Moravian state, in order to oppose German political and ecclesiastical

influence and the joint pressure of the East Frankish kingdom and Bulgaria, sent to Constantinople asking for Greek support and missionaries. The Byzantine emperor Michael III and the patriarch Photius entrusted that mission to the two brothers. In the following year they started their work among the Slavs, using the native language in the liturgy. They translated the Holy Scriptures into the language later known as Old Church Slavonic (*q.v.*), and invented a Slavic alphabet based upon Greek characters which in its final form was called Cyrillic and still is used by all Slavs belonging to the Eastern Church.

In 867 the brothers accepted an invitation of Pope Nicholas I to go to Rome to explain their conflict with the German archbishop of Salzburg and bishop of Passau, who claimed control of the same Slavic territory and wanted to enforce there the exclusive use of the Latin liturgy. The two brothers arrived in 868 in Rome, where the new pope, Adrian II, took their side, formally authorizing the use of the Slavic liturgy. When Constantine (renamed Cyril on taking his monastic vows) died the following year, the pope sent Methodius back to the Slavs as his legate and archbishop of Syrmium.

From this metropolitan see at the southern border of Pannonia (the future Hungary) Methodius' ecclesiastical province extended as far as Slovakia and Moravia, where the Great Moravian state had its main centres. Rostislav's nephew and successor, Svatopluk, however, co-operating at first with King Louis the German, failed to support Methodius. In 870 the archbishop was tried by the German clergy, probably at Freising in Bavaria, brutally treated and kept in jail for about three years, until the energetic intervention of Pope John VIII resulted in his liberation. A few years later, however, he was again summoned to Rome over the question of the Slavic liturgy. On the occasion of that visit, in 880, he obtained once more, though not without difficulty and reservations, papal approval of his use of the native language. But a German named Wiching, who was made his suffragan bishop, continued through his intrigues to create troubles for Methodius, who tried to strengthen his position by visiting Constantinople in 882. After Methodius' death in 885 Wiching succeeded in taking the place of the Slavic successor whom Methodius had chosen, and forced the disciples of the two Greek brothers to leave the country. They found a haven in recently christianized and Slavified Bulgaria. While the Moravian state collapsed under German and Hungarian attacks at the beginning of the 10th century, the posthumous influence of Cyril and Methodius reached distant Kiev and left traces even among the Slavs of Croatia, Bohemia and Poland who ultimately adopted the Latin liturgy. Soon canonized by the Eastern Church, the two apostles of the Slavs were recognized as saints also by the Roman Catholic Church in 1880. Their feast day is July 7.

**BIBLIOGRAPHY.**—The bibliography on Cyril and Methodius published in 1934 by G. A. Ilinski comprised more than 3,000 items. The basic studies of F. Dvornik, *Les Slaves, Byzance et Rome au IX<sup>e</sup> siècle* (1926), and *Les légendes de Constantin et de Methode vues de Byzance* (1933) are summarized in his book *The Slavs, Their Early History and Civilization* (1956). See also the articles by V. Jagić "Conversion of the Slavs," in *Cambridge Medieval History*, vol. iv (1927), and P. J. Alexander, "The Papacy, the Bavarian Clergy and the Slavonic Apostles," in *The Slavonic Year-Book* (1941). (O. Ha.)

**CYRILLIC ALPHABET:** see ALPHABET; OLD CHURCH SLAVONIC; SLAVIC LANGUAGES.

**CYRUS**, the Latin form of Old Persian Kurush, the name of three members of the Achaemenid house (see ACHAEMENIDAE.)

**CYRUS I**, son of Teispes and grandfather of Cyrus the Great, ruled over Anshan during the latter half of the 7th century B.C. He accepted Assyrian overlordship about 639 B.C., after the conquest of Elam by Ashurbanipal, and sent his eldest son, Arukku, with tribute to Nineveh.

**CYRUS II the Great**, who reigned from 559 until his death in 530 B.C., was the founder of the Persian empire. His father was Cambyses I of Anshan.

Legends about the birth of Cyrus were soon current. Herodotus mentions a tradition that he was the son of Cambyses and Mandane, daughter of Astyages of Media, was exposed in the mountains, suckled by a bitch and brought up by a shepherd. The version Herodotus follows changes the dog into a shepherd's wife. Other traditions are preserved in Nicolaus Damascenus.

The principal sources for the history of Cyrus are cuneiform documents, the Old Testament and the Greek historians. The most important cuneiform texts are the *Cyrus Cylinder* and the fragmentary verse account of Nabonidus, both composed in the reign of Cyrus, and the Nabonidus Chronicle, written between the 5th and 3rd century B.C. In the Old Testament there are references to Cyrus in II Chronicles, Ezra and Isaiah. Herodotus, Xenophon, Ctesias and the excerpts from Berossus contain historical material, although there is much that is legendary and dubious.

Cyrus, who had become king of Anshan in 559, rebelled against Astyages, his Median overlord, in 553 B.C., having previously united the leading Persian tribes under his rule and secured an alliance with Nabonidus of Babylonia. In 550 B.C. he defeated and captured Astyages and seized Ecbatana. Although he had received assistance from disaffected elements among the Medes, his victory did not lead to immediate acceptance of his rule by all the members of the Median confederation, and he may have spent the next two years in securing the submission of tribes east of the Tigris. The Nabonidus Chronicle states that in the spring of 547 B.C. Cyrus marched into north Mesopotamia and then proceeded against a land, the name of which is broken, and killed its king. It is possible that the enemy was Croesus of Lydia, who, according to Herodotus, was seeking to expand his power into the former Median territory east of the Halys river. After an indecisive battle with Cyrus, the king retired to Sardis and disbanded his mercenaries, his intention being to renew the war in the following spring when he had received reinforcements from Babylonia, Egypt and Sparta. Cyrus, however, forestalled him by a swift advance on Sardis, which fell after a short siege. If Lydia is the land referred to in the chronicle, the most probable date for this event is the autumn of 547 and, contrary to classical traditions, Croesus was killed by Cyrus.

Herodotus and Berossus agree that between the fall of Sardis and the final campaign against Babylon in 540 B.C. Cyrus made himself master of the rest of western Asia. The reduction of western Asia Minor was completed by his generals, who, by force or persuasion, secured the submission of the Ionians, Carians and Lycians and suppressed a revolt in Lydia. The king of Cilicia voluntarily acknowledged Persian supremacy, as did Gutium, a Babylonian dependency east of the Tigris. According to Xenophon, Cyrus also subdued Greater Phrygia and Cappadocia and reduced the Arabs to submission. The term "Arabs" may here refer to the peoples of the Damascus area and Palestine who had previously formed part of the Babylonian empire.

By 540 B.C., when Cyrus began his attack on Babylonia, he had gained control of most of its provinces. In Oct. 539 his general Gobryas entered Babylon without a battle. The story, given by Josephus and Eusebius, that Cyrus spared Nabonidus is contradicted by Xenophon.

Cyrus was welcomed by many of the Babylonians who had been alienated by the religious policy of Nabonidus. In his *Cylinder*, a masterpiece of propaganda, Cyrus represents himself as their liberator from the evil rule of Nabonidus and as the king chosen by Marduk, their national god, to reign over them. He assumed the Babylonian royal titulary, and although he himself did not perform the ritual duties of a Babylonian king at the New Year festival of 538 B.C., his eldest son, Cambyses, did so as his representative. A Persian governor was appointed, but many native officials were retained in their posts. Cyrus scrupulously respected the Babylonian religion; he repaired temples and restored to their cities the cult statues that had been brought into Babylon by Nabonidus. He also sent back the gods of Ashur and Susa and in 538 B.C. authorized the return to Palestine of the Jews deported by Nebuchadnezzar and made arrangements for the rebuilding of the Temple in Jerusalem.

The subjugation of northern and eastern Iran must also be attributed to Cyrus, although his campaigns in these areas are not well documented. Immediately after the defeat of Astyages, according to Nicolaus Damascenus, Cyrus was acknowledged as overlord by the Hyrcanians and subsequently by the Parthians, Bactrians and Sacae. Herodotus implies that he subdued the

Bactrians and Sacae after the fall of Lydia. The historians of Alexander the Great mention that Cyrus received aid from the Ariaspae tribe on the Etymandrus and founded a fortress, Cyropolis, on the Jaxartes river, and that in a march through Gedrosia (southeast Iran and Baluchistan) he lost the greater part of his army. In 530 B.C., having appointed Cambyses as regent in Babylonia, Cyrus set out on a new expedition against the east in the course of which he was killed. He was buried at Pasargadae, the city he had founded.

Cyrus was an outstanding soldier and statesman. He founded an empire that stretched from the Indus and Jaxartes to the Aegean and the borders of Egypt and left behind him a reputation for justice and clemency, which, while in the main justified, undoubtedly owed much to his skilful use of propaganda. (See also PERSIAN HISTORY.)

CYRUS the Younger (d. 401 B.C.), the son of the Persian king Darius II, was born after the accession of his father in 423 B.C. He was the favourite of his mother, Parysatis, who hoped to secure the succession for him instead of her eldest son Arsaces. When, after the victories of Alcibiades, Darius II decided to continue the war against Athens and give support to the Spartans, she persuaded him to appoint the young Cyrus as satrap of Lydia, Phrygia and Cappadocia and commander in chief of the Persian forces in Asia Minor (407 B.C.). The Spartan general Lysander won the favour of Cyrus and after the Athenian victory at Arginusae (406) Cyrus used his influence in Sparta to secure the appointment of Lysander as commander of the Spartan fleet, although under a nominal chief. In 405 B.C. Cyrus was called to his father's deathbed but before leaving handed over the revenues of his province to Lysander, who the same year won the battle of Aegospotami. In 404 B.C. when Arsaces became king as Artaxerxes II, Cyrus was accused by Tissaphernes, satrap of Caria, of plotting his brother's murder, but on the intercession of Parysatis he was pardoned and sent back to his satrapy.

Immediately on his return, Cyrus began preparations to seize the throne. He used a quarrel with Tissaphernes over the Ionian cities as a pretext for gathering a large army and also pretended to prepare an expedition against the Pisidians, a tribe in the Taurus mountains. The Spartans, while not breaking openly with Artaxerxes, gave Cyrus every facility for recruiting Greek mercenaries; a Spartan exile, Clearchus, raised troops for him in Thrace and Menon of Larissa collected another army in Thessaly. In the spring of 401 B.C. Cyrus started from Sardis; he was subsequently joined by Menon and Clearchus and, on reaching Cilicia, by his fleet and a Spartan squadron. When he reached the Euphrates at Thapsacus Cyrus announced that he was marching against Artaxerxes and by dexterous management and large promises overcame the misgivings of the Greek troops at the prospect of a long and dangerous war. He advanced into Babylonia without meeting any opposition, but Artaxerxes, warned at the last moment by Tissaphernes, was hastily gathering an army. The two forces met at Cunaxa and in the ensuing battle Cyrus was slain. The Greek troops of Cyrus, after their commanders had been treacherously seized by Tissaphernes, forced their way to the Black sea.

The courage and ability of Cyrus are highly praised by the Greeks, especially by Xenophon, who in his *Anabasis* wrote the history of the Greek retreat, but from the standpoint of Persia Cyrus was a traitor who, to gain his own ends, used hostile Greeks to attack the empire.

**CYSTIC FIBROSIS:** see CHILDREN, DISEASES OF.

**CYSTOID**, any of the fossil echinoderms (relatives of present-day starfishes, sea urchins, etc.) constituting the class Cystoidea. They were characterized by a globular or cystoid shell. See ECHINODERMATA.

**CYSTOLITH**, a botanical term for the inorganic concretions, usually of calcium carbonate, formed in a cellulose matrix in special cells, generally in the leaf of plants of certain families; e.g., *Ficus elastica*, the india-rubber plant.

**CYTOLOGY:** *see* CELL.

**CYZICUS**, an ancient town of Mysia, the ruins of which are situated on the shoreward side of the Kapidagi (Arctonessus) peninsula on the south coast of the Sea of Marmara in the Bali-Kesir *il* of Turkey. It is said to have been a colony of Miletus, founded in 756 B.C. Its advantageous position soon gave it commercial importance, and its electrum staters were a staple currency in the ancient world till they were superseded by Alexander the Great's world coinage. Cyzicus came under Persian rule on the collapse of Lydia (c. 546 or 540) but joined the Delian league (q.v.) after the defeat of Xerxes and remained loyal to Athens till 411 B.C.

Assigned to Persia, with the other Greek cities of Asia, by the peace of Antalcidas (387), it was freed by Alexander's invasion. The history of the town in Hellenistic times is closely connected with that of the dynasts of Pergamum, upon whose extinction it came into direct relations with Rome. Cyzicus was held for the Romans against Mithradates in 74 B.C. till the siege was raised by Lucullus; its loyalty was rewarded by an extension of territory and other privileges.

Still flourishing in imperial times, Cyzicus was partly destroyed by the Arabs in 675 and appears to have been further damaged by a series of earthquakes. The principal extant ruins are the walls, traceable for nearly their whole extent; a picturesque amphitheatre intersected by a stream; and the substructures of the temple of Hadrian, which was sometimes ranked among the seven wonders of the world (31 immense columns still stood in 1444). Excavations on the site were undertaken in 1959 under the supervision of Ekrem Akurgal of Ankara university.

*See* F. W. Hasluck, *Cyzicus* (1910).

**CZAPLICKA, MARIA ANTONINA** (1886–1921), Polish-English anthropologist best known for her works on the peoples of northern Siberia and the Turks of central Asia, was born near Warsaw, Poland, in 1886 and went to England early in her career to complete her university work. She studied at the universities of London and Oxford. From 1912 on, she lectured at both universities and later at Bristol university, where she was at the time of her death on May 27, 1921. Through her mastery of Slavic languages she was able to interpret the anthropological studies of Siberia and central Asia for the English-speaking world. In 1914–15 she led, together with Henry U. Hall of the University of Pennsylvania, an expedition to the Samoyed and Tungus peoples of Siberia. Some of the findings of the expedition are incorporated in a vividly descriptive work, *My Siberian Year* (1916). The more purely scientific results of the expedition have remained unpublished.

In two general works of excellent scholarship, *Aboriginal Siberia: a Study in Social Anthropology* (1914) and *The Turks of Central Asia in History and at the Present Day* (1918), she reviewed virtually all then-known aspects of the ethnology of the peoples of Asiatic Russia. Her surveys are unsurpassed for succinctness, clarity and good judgment. Her literary remains include unpublished lectures for the London county council, 1920. These go into questions of the history and economy of Siberia; there is also an unfinished manuscript on Poland. (L. K.)

**CZARNIECKI, STEFAN** (1599–1665), was the foremost Polish general of his age. As a young man he fought in the Prussian campaigns against Gustavus Adolphus (1626–29) and under Wladyslaw IV in the Muscovite campaign of 1633. In 1648 he fought the Cossacks and the Tatars at Zheltye Vody and was captured by the latter, being freed in 1649. Two years later he helped to defeat the Cossacks at Beresteczko. When Charles X of Sweden invaded Poland (1655), Czarniecki led the national rising and carried on a partisan campaign which contributed to the defeat of the Swedes. In 1658–59 he helped the Danes in their war against Sweden. After the peace of Oliva (1660) he fought against Russia, winning victories at Polonka and the Basia river. He died at Sokolowka, near Brody, on Feb. 16, 1665, just after he had been appointed deputy commander in chief. Under him Jan Sobieski learned the art of war.

(St. Hx.)

**CZARTORYSKI**, a Polish princely family, descended from the ruling dynasty of Lithuania. The family seat was the Czartorysk castle on the Styr river in Volhynia. In the 15th century the

sons of Prince Wasyl Konstantynowicz were Orthodox and anti-Polish, and one of them, ALEKSANDER, murdered Zygmunt Kiejstutowicz, grand duke of Lithuania (1440). Settling in Moscow, he played a part in the internal struggles there and became viceroy of Pskov (1443) and Novgorod (1447). He returned to Lithuania in 1462 and died there after 1477.

At the end of the 16th century the Czartoryskis became Roman Catholics and favoured closer union with Poland and held senatorial office. The founder of a strong family party, the so-called Familia, was KAZIMIERZ (1674–1741), treasurer and later vice-chancellor of the grand duchy of Lithuania, who was opposed to Russian influence. The Familia attained great power through the activities of his sons, ALEKSANDER AUGUST (1697–1782) and MICHAL FRYDERYK (1696–1775). The former, governor (*wojewoda*) of Ruthenia, was a highly competent landlord, who gathered together a great estate and founded workshops, forming a strong financial basis for the party.

Aleksander August's son, ADAM KAZIMIERZ (1734–1823), born in Danzig on Dec. 1, 1734, was educated in England and prepared to take over the Polish throne. The political leader of the Familia in Poland was his uncle Michal Fryderyk, chancellor of the grand duchy of Lithuania. The policy of the Familia was to strengthen the state, with the backing of Russia and England, in opposition to the Potocki party, supported by Austria and Prussia. In the period when Poland was left without an elected king, Adam Kazimierz refused the crown (1763), which was accepted by his first cousin, Stanislaw August Poniatowski. The interests of Adam Kazimierz were mainly literary and pedagogical. In 1763 he launched the publication of *Monitor*, a periodical in the style of the English *Spectator*. In 1768 he accepted command of the newly formed cadet corps, which was in fact the first Polish lay school. He wrote for it the *Cadets' Catechism*, formulating in it the ideal of education in the spirit of the age of enlightenment. He also rendered great service to the educational commission and became the first minister of education in the world. In addition, he fulfilled with zeal his duties as lieutenant-general (up to 1783) in command of the Lithuanian army. By his efforts and those of his ambitious wife, Izabella Elzbieta, née Countess Flemming (1746–1835), their palace at Pulawy became an important centre of culture competing with royal patronage in the support of classical architecture and Polish literature; this provided an excellent school for their sons and those of the local gentry. The economist P. S. Du Pont de Nemours taught there. A supporter of the Polish theatre, Adam Kazimierz wrote several comedies for his Pulawy theatre. His daughter, Ludwika Maria, unhappily married to the prince Ludwig of Württemberg, wrote popular sentimental novels. As a politician Prince Adam Kazimierz allowed himself to be drawn into anti-royalist circles. However, he showed his loyalty during the vote of the 1791 constitution. After the downfall of Poland in 1795, Pulawy, ruined in 1792–94 and rebuilt, became the shrine of the country's past, mainly through Princess Izabella's efforts. In 1800 the "temple of remembrance" (now called Sybilla's temple) was built to house souvenirs of the Polish kings and leaders. The so-called "Gothic house," inaugurated in 1809, was the first Polish museum. Prince Adam Kazimierz died at Sieniawa on March 19, 1823.

The son of Adam Kazimierz and Izabella, Prince ADAM JERZY (1770–1861), born in Warsaw on Jan. 14, 1770, was the most renowned member of the family. Having received a thorough education in his native country, he later traveled widely in Germany (where he met Herder, Wieland and Goethe), France, Switzerland, Holland, and, above all, in England and Scotland. He studied in Edinburgh, was present at parliamentary sittings, visited estates and factories and made contact with great families such as the Argylls, Lansdownes and Straffords, who were of great help to him in the years 1814 to 1831. While in England he formulated his program of liberal torism. On returning to Poland in 1791 he played a distinguished part in the 1792 campaign against Russia. On the advice of his parents he took no active part in the 1794 insurrection; nevertheless, Pulawy palace was destroyed and his estates confiscated.

Seeking the recovery of his property, Adam Jerzy went in 1795 to

St. Petersburg, where he became friendly with the grand duke Alexander. When Alexander became emperor he called upon Czartoryski to work out a plan for the reform of the government, appointing him deputy minister of foreign affairs in 1802 and minister in 1804. Czartoryski advocated world peace, based on an Anglo-Russian understanding; he also supported the liberation movements in the Balkans. He worked unsuccessfully for the restoration of Poland and its union with Russia. The Russian military defeat in the 1805 campaign against Napoleon, undertaken against his advice, caused his dismissal in the spring of 1806. However, he remained in Russian service until 1824 as curator (from 1803) of the educational region of Wilno, which embraced the eastern provinces of the former Polish state. He attained great success in the extension of Polish schools and of Wilno university. In 1812 the Poles, under the nominal leadership of his father, Prince Adam Kazimierz, sided with Napoleon. After Napoleon's downfall Adam Jerzy resumed his efforts to restore Poland and obtained from Alexander a promise to unite to that country the former Polish lands of Lithuania and Ruthenia. Czartoryski also sought for English support. With Alexander's consent he was Poland's spokesman at the congress of Vienna in 1815, obtaining as much as was possible; i.e., the creation of a kingdom of Poland with Alexander as king. In his capacities as senator and member of the government he helped to prepare a liberal constitution, but in 1816, disillusioned with Alexander, he withdrew from public life. In 1827 he published, under the pseudonym Filhellène, his *Essai sur la diplomatie*, in which he proposed a league of nations for the defense of world peace.

Although he opposed war against Russia, Czartoryski found himself at the head of the Polish insurrection that broke out on Nov. 29, 1830. He saw that its success would depend more on western diplomatic intervention in Poland's favour than on actual fighting by the Poles. On the collapse of the insurrection, Czartoryski, sentenced to death by the Russians and deprived of his estates, left Warsaw on Aug. 15, 1831, and went into exile. The "Hôtel Lambert," his Paris residence, became a centre of Polish political activities. Maintaining unofficial envoys in Constantinople and Rome and having many lesser agents abroad, Czartoryski was always well-informed; once again he bent all his efforts to restoring Polish independence. From 1836 he paid special attention to events in the Balkans and Turkey. Wishing to undermine Russian influence there, he encouraged the national movements of the Balkan peoples and later, with the support of Turkey, the Caucasian national movements. During the years immediately preceding the Crimean War this also served the interests of the western powers, especially of Great Britain. Maintaining contact with Poland, Czartoryski took an important part in the preparation of the 1863 insurrection, though he did not live to see it. He hoped that, under the pressure of public opinion, the British and French governments would help to restore Poland's independence. As, at the same time, he was opposed to social revolutionary movements, he was sharply criticized by Polish radicals. He died at Montfermeil, France, on July 15, 1861.

WŁADYSŁAW (1828–1894), the younger son of Adam Jerzy, born in Warsaw on July 3, 1828, continued his father's policy and, during the 1863 insurrection was the chief diplomatic agent abroad for the Warsaw underground national government. He was successful in organizing unified opinion against Russia and its Prussian allies and came to an understanding with the Russian revolutionary emigration. When, however, it became clear that diplomatic intervention was not to be supported by armed action, he resigned from his official functions and called upon his country to cease fighting. From that moment Władysław Czartoryski's political activities flagged. He turned his main interest to cultural affairs. In accordance with his father's will he set about saving the family historic and artistic collections, starting with those from Pulawy, and in 1876 founded the Czartoryski museum in Cracow, one of the richest in eastern Europe. The family archives and collections of manuscripts are one of the main sources of research into Poland's history. He died at Boulogne-sur-Seine, France, on June 23, 1894.

AUGUST FRANCISZEK (1858–1893), Władysław's son, did not continue his father's political activities. A mystic, he became a mem-

ber of the Salesian Order.

**CZECH LANGUAGE.** Czech is the native language of Bohemia; Moravia, and Silesia, all within the Czechoslovak Republic; the Slovak language is the official language in Slovakia. Recent sporadic attempts to merge Czech and Slovak have failed, although they are the two least differing Slavonic languages and the territories in which they are spoken have long cultural affinities and have been politically joined since 1918. Czech has about 9,000,000 speakers.

**Etymology.**—The older name of the language, Bohemian, is from Boii, a Celtic tribe transient in Bohemia ("the home of the Boii") before the Christian era. In Old German it became *Boheim*; it was Latinized *Bojohemum* and *Bohemia*; and in modern German it became *Böhmen*. Czech is considered, by some, hypocoristic: derived from a proper name (Čestislav). According to tradition, Čech was the name of a Slavonic leader. Other conjectures about the etymology of Czech are equally uncertain. The Czech term for Czechoslovakia's western part is Čechy; Czech people are *Čech* (sing.) or *Češi* (pl.); and the adjectival form is *český*.

**Classification.**—Western Slavonic languages, namely Czech, Slovak, Lusatian (Wendish, Sorbian) and Polish, are separated from other Slavonic languages (see SLAVIC LANGUAGES) by a fixed stress. Czech differs from others in this group as follows:

1. Czech, like Slovak, retains the original vocalic quantitative differences, unlike Polish and Lusatian (and Russian and Bulgarian), where only the semi-short vowel remains.

2. Czech, like Slovak, preserves the clusters *ra*, *la*, while Polish and Lusatian have *ro*, *lo*. For example, the Old Church Slavonic (and modern Bulgarian and Serbian) word *glava* ("head") becomes *hlava* in Czech and Slovak, *głowa* in Polish and Lusatian and *golova* in Russian.

3. Czech stress, like Slovak and standard Lusatian, is always on the first syllable of a word or prepositional phrase, even in loan words and naturalized foreign expressions; in Polish the stress is on the penultimate. The diacritical sign ' (*čárka*) indicates the vocalic length only, not the stress: *páni* ("gentlemen") and *paní* ("lady") both have the stress on the first syllable, although the vocalic quantities differ. The stress is not normally written.

4. Czech, like all other Slavonic languages, except Polish, replaced the original nasals by pure vowels: Old Church Slavonic *rpka* ("hand") becomes *ruka* in Czech, Lusatian, Serbian, Slovak, Russian and Bulgarian, and *reka* in Polish.

**History.**—The Czech version of Slavonic of the 6th to 10th centuries was probably not very different from Old Church Slavonic (*q.v.*). Single Czech words intermixed in Old Church Slavonic bear testimony of the oldest stage of Czech as early as in the 11th century. Czech glosses appear in Latin and German texts of the 12th century. Czech literature proper, however, began in the 13th century, although there was no uniform language at that time. Dialects and provincialisms were marked. Phonetic changes entailed spelling changes that took place in three main periods:

1. *The Old Period (11th to 14th centuries).*—Penetrating changes occurred during this period. Characteristics of Czech, differentiating it from other Slavonic languages, were: mutation *a-ě*, *u-i* (*duša-dušě*, *dušu-duši*); narrowing *ě-i* (*řéci-řici*); monophthongization *ie-i* (*viera-vira*); diphthongization *o-uo* (later: *ů*), *u-ú-ou* (*bóh-buoh*, *luka-lúka-louka*). Nominal and especially verbal inflexional variety was reduced. The dual number was weakened and often neglected in favour of the plural. (In modern Czech, the dual is nearly extinct, except in declension of *dvě*, *obě*, *ruce*, *oči*, *uši*, *nohy*.) Three past tenses were reduced to one: the aorist *ved/ech* and the imperfect *vediech* were replaced by the periphrastic *vedl jsem*.

2. *Middle Czech (15th and 16th centuries).*—The great religious reformer John Huss (c. 1370–1415) was also an ingenious and successful innovator in Czech, both in vocabulary and orthography. A standardization set in with his far-reaching simplification of

spelling, based on phonetic adaptation of the Prague dialect which he popularized in his own numerous writings. Huss introduced diacritical signs ' and ˇ which have survived up to the present. Lexical resources grew with neologisms and adopted words, mostly from the Latin, brought in with the Latin-German Christianity, French and German courtly life and German colonization. For example, the Latin *missa* became *mša* (later *mše*, "mass") and *crux* became *křiž* (later *kříž*, "cross"). German and French military terms entered the language from the 13th century onward, such as the German *Ritter* which became *rytiř* (later *rytíř*, "knight"). The humanism of the 16th century had profound effects on syntax, word order and vocabulary. The *Bible kralická*, 1593, served as a standard of usage.

3. *Modern Czech*.—In the subsequent period of the Habsburg regime in the Czech countries (1620 to 1918), political and cultural germanization nearly suppressed Czech. Linguistic revivalists from this period of semistagnation were J. Dobrovský, J. Jungmann, P. Šafařík, J. Gebauer and L. Niederle. The prolific linguistic production in Czechoslovakia during recent decades pertains mainly to the Czech language. See CZECHOSLOVAK LITERATURE.

**Phonology**.—The Czech alphabet, of Latin type, consists of all the letters of the English alphabet of sound value (q, x and w are found in foreign words only), with these additions: ě (as in the English word *catch*); ě (did you); ě (yes); ň (canyon); š (ash); ě (hit you); ě (measure); ř is ř. Diacritical marks indicate the quantity of vowels and the quality of consonants. (1) *ěarka* (literally, virgule): á, é, í, ó, ú, ý. It indicates the length, never the stress. (2) *kroužek* (little circle): ů (from older *uo*). It is also long and is only found over *u* medially and finally. (3) *háček* (little hook): e.g., ě, ě. It indicates soft pronunciation (palatalization). Among vowels, only *e* carries the "hook." In combinations of a consonant and ě, the "hook" is found on ě, ř, š, ž; otherwise it is only found on ě: *čestina, řeka, děti, němčina, těšiti, město, ofěra*.

*Di, ti and ni* are soft (*dyi, tyi, nyi*) in Slavonic words: *nyin* (now); in foreign words, even domiciled, they are always hard (as in the English d, t, and n): *finiš, difúze, Titanic*. *Dy, ty and ny* are hard. Czech has no slurred or reduced vowels or consonants. All the sounds are fully pronounced. Exceptions are less striking than in English. Voiced *b, d, g, v, z* are unvoiced *p, t, k, f, s*, respectively before a voiceless consonant: *podzim* (-dz-, "autumn"), but *pod paží* (-tp-, "under the arm"). Similarly, *p, t, k, f, s* are voiced before a voiced consonant: *kde* (gde, "where"). In foreign words, *s* is voiced after *n, l, r*, or between vowels: *universita, fysika* (-z-), but *zase* (zasse, "again"). The *y* is the same as *i*; *r* is trilled, like Italian or Dutch; *l* and *r* may be syllabic: *plný, trn*. The pronunciation *ou* is as in English *go*; *ch* like the German in *ack*. Simple vowels are not diphthongized regardless of length: *láka* (laakaa, "lures"). All diphthongs are written as such: *au, ou, aj, ej, oj*; *u* is rounded as in *food*. The phoneme *ř* is closest to *rž*: *Dvořák*. In final position *v* is unvoiced: *lev* (lef, "lion").

**Morphology**.—Modern Czech has nine parts of speech; seven cases; two numbers; three persons; three tenses (present, past and future, all modified in verbal aspects); two voices; and three moods (indicative, imperative and conditional, including subjunctive). It lacks the article and the so-called "emphatic" verbal forms. It has, however, verbal aspect, a marked feature of Slavonic languages. Basic aspects are perfective and imperfective (durative, iterative), indicated by an internal change (*nésti, nositi, nosivati*). Some verbs modify these aspects further by numerous prefixes, connoting varieties of action as well as of time (*nésti: roz-, za-, pro-, při-, pře-, u-, do-, vy-, s-, na-, v-, vz-, nad-, od-, po-, popo-*).

**Dialects**.—Dialectal differences are now slight, lexically and phonetically. The most popular dialects in Bohemia are: (1) in the southwest, the dialect of Domažlice (*chodské nářečí*: *bul* for *byl*, "was"); (2) the central dialect (of Prague), the basis of the standard written Czech; (3) the dialect of Krkonoše Mountains, in the northeast. In Moravia and Silesia the dialects are: (4) the dialect of Haná, around Olomouc (*bel* for *byl*); (5) the Valach dialect in the northeast; (6) the Silesian dialect, with Polish ele-

ments; (7) the Moravian Slovak dialect, in the southeast, similar to Slovak.

**CZECHOSLOVAKIA** (ČESKOSLOVENSKÁ SOCIALISTICKÁ REPUBLIKA), a landlocked, elongated country of central Europe. Area 49,371 sq.mi. (127,870 sq.km.). The most noticeable feature of configuration is the disproportion between length from north to south and breadth from east to west. The caterpillar outline of the country, truncated in the east with the cession of Subcarpathian Ruthenia to the Soviet Union after World War II, stretches across the heart of Europe. Czechoslovakia has common frontiers with the German Federal and Democratic republics, Poland, the U.S.S.R., Hungary, and Austria. The western regions, Bohemia and Moravia-Silesia, have been for centuries the westernmost settlement area of the Slavonic peoples, thrust like a wedge between the Saxons to the north and the Bavarians to the south.

## I. PHYSICAL GEOGRAPHY

1. **Geology and Physiography**.—The lands of the Czechoslovak republic belong in structure to two contrasting sets of physical features in Europe. To the west, the Czech part of the country lies wholly within the Hercynian highland area of the Bohemian Massif. To the east, the greater part of Slovakia is a section of the large Tertiary arc of the Carpathian Mountains (*q.v.*). In the centre, Moravia and southern Silesia are geological and structural borderlands. Western Moravia, mainly Czech in tradition, is the

easternmost part of the Bohemian Massif. Eastern Moravia, mainly Slovak, belongs to the outer foothills of the White Carpathian and Javorníky ranges. Lowland Moravia, like the plains of southern Slovakia, formed in the Miocene Period the northern inlets of the great sea which covered the whole Middle Danube Basin. The thick and sometimes very fertile Tertiary deposits are characteristic also of the broad lower valleys of the North Carpathian river basins. In Czechoslovak Silesia are the southernmost traces of the Pleistocene ice sheets. In physical geography, therefore, Czechoslovakia lies at the crossroads of Europe.

*The Bohemian Massif.*—The high country reaches a maximum elevation of 5,256 ft. (1,602 m.). The effect in landscape is of rounded, forested, rather monotonous highland, mainly of Archean crystalline rock. Four bounding ranges frame the massif: the Erzgebirge or Krušné Hory (Ore Mountains) in the northwest, the Riesengebirge or Giant Mountains (*q.v.*; Krkonoše) in the northeast, the Moravian Heights in the southeast, and the Šumava and Český Les (Bohemian Forest; *q.v.*) in the southwest. Only the Moravian Heights are wholly within Czechoslovakia. Bohemia shows plainly not only the effects of long-continued erosion and submergence, but also the effects of the violent folding and thrusting in the Alpine region to the south. The massif contains much evidence of tilting, faulting, and breaking. In the northern hills, variety is given to the landscape by the Cretaceous sandstone covering, which is elsewhere almost wholly worn away. This warm, beautifully coloured rock in the Lužické Hory (Lusatian Mountains) and in the Elbe gorge on the Czech-Saxon border accounts for a small region of fine scenery with spectacular rock formations. Former volcanism explains the number of spas in northwest Bohemia.

In the inner part of the massif four contrasting types of lowland are separated from each other by wide stretches of thinly settled rugged country, mainly of crystalline rock. In the northeast is the Upper Elbe plain with the regional name of Polabí. It is a small region of Cretaceous marls, largely covered with fertile loess. Polabí is the heartland of Bohemia, with its ancient and now dense settlement. In the south are the two lake basins of Třeboň (Wittingau) and Budějovice (Budweis) through which flow the Lužnice and Vltava (Moldau) rivers. These are curious areas of heavy impermeable Tertiary clays on which some peat has formed. The remarkable distribution of the *rybník* (small lakes and ponds) and their exploitation for freshwater fisheries make these localities both distinctive and interesting. In the west and centre are the Plzeň and Kladno basins both with coal measures of limited economic importance. In the northwest, in the Ohře (Eger) and Blžná basins, the Oligocene lignite beds form the main reason for two considerable mining and manufacturing regions.

The whole is given an apparent coherence by the pattern of the river system. The Elbe rises in the Krkonoše and flows south, west, and north to the German frontier. It is joined near the

western end of Polabí by the Vltava which rises in the Šumava Mountains in the south. The right-bank tributaries of the Vltava, the Lužnice, and the Sázava are large streams, as are the left-bank rivers, the Otava and the Berounka. The convergence of waterways above and below Prague, which occupies both banks of the Vltava downstream from the St. John's Rapids, is remarkable. Most of the Bohemian rivers have upper courses of shallow valleys and gentle gradient, but many have rugged, tortuous middle courses. Navigation is therefore strictly limited, and the development of road and rail communications converging on Prague was achieved in spite of natural difficulties.

*Slovakia.*—The broad arc of the North Carpathians (*see* CARPATHIAN MOUNTAINS) in Slovakia forms the greater part of the region. Their general character is of open block mountains with the groups of ranges separated from each other in the west by the great valley of the Váh, and in the north and east by upland basins of some individuality. In the north the Tertiary fold ranges are continuous from the White Carpathians in the west, far beyond the eastern frontier of Slovakia to the Transylvanian Alps of Rumania. These flysch (*q.v.*) mountains are not very high, but they form a broad, thickly wooded outer belt of the arc. They are a major part of the Carpathian landscape. The exposed core of crystalline rock provides the finest scenery, and is most noticeable in the High (Vysoké) and Low (Nizké) Tatras groups. The High Tatras contains a line of fine jagged peaks, and evidences of glaciation are also present in the frequent cirque formations and in the number of small tarns which fill the cirque hollows. Limestone ranges, relatively small in extent, lie mostly to the west of the Tatras Massif (*see* TATRAS MOUNTAINS) and are mainly conspicuous in parts of the Lesser (Malá) Fatras and the Greater (Veľká) Fatras ranges. One section of the Váh Valley between Liptovský Svätý Mikuláš and Žilina is a magnificent gorge of Triassic limestone crags. Beyond the limestone and crystalline hills are the volcanic highlands, of moderate altitude and stretching away in scattered outcrops to the Slovak and Hungarian plains. The inner side of the curve of the North Carpathians contains the lines of fracture surrounding the depression of the Middle Danube Plain. These lines of weakness formed the vents for the outpouring of volcanic material and explain the rich soils, especially suited to vineyards, in parts of Slovakia and north Hungary.

There are few lakes and therefore no natural check to the marked seasonal runoff in the southward flowing streams: the Váh and the Hron, the Ipel, and the great fan of tributaries which form the upper part of the Tisza (*q.v.*) Basin. The careful maintenance of the forest cover which could lessen the violence, especially of spring flooding, has often, unfortunately, been neglected in the traditional and rather primitive use of woodland in Slovakia.

The smaller region of lowland Slovakia to the south is a part of the great basin of Hungary. To the west the Slovak plains are the northern extremity of the Little Alföld (or lowland), and to the east they form the tip of the Great Alföld. On the western side the meandering streams of the Middle Danube form the southern frontier. The southern part of the Slovak plains is alluvial farming land reclaimed from natural marsh by diking and drainage. The northern part has fertile loess material which continues in the valleys of the Váh, Nitra, and Hron rivers both in the Little and the Great Alföld. The distinctions in relief are the more noticeable because traditionally the plain settlement is that of the Magyars, who penetrated right into the Carpathians, while the hill country settlement is that of the Slovaks.

*Moravia-Silesia Borderland.*—Between the two contrasting re-

CZECHOSLOVAK NEWS AGENCY

RUINED CASTLE OF ZVÍKOV ABOVE THE VLTAVA RIVER IN SOUTHERN BOHEMIA

gions of west and east lies the border country of Moravia-Silesia (Moravia means a border region). The demarcation between the Hercynian and Alpine areas is buried below the thick Miocene deposits with their rich loess covering. This good farming land runs in well-marked zones below the Moravian Heights from the Austrian frontier to the upper basin of the Morava River. In sharp contrast is the spectacular Moravian Karst (Moravský Kras) landscape (see KARST) to the north of Brno. This is formed in Devonian limestone much fragmented, interspersed with Carboniferous schists, and partially covered with Jurassic and Miocene beds. Its curious topography of large caverns, swallow holes, and underground streams, together with the great Macocha gorge (600 ft. deep), developed during the Paleozoic era and have become apparent once more through the processes of denudation.

EAST PHOTO

IN NORTHEASTERN BOHEMIA

Carpathian Moravia is more remote, more monotonous, and poorer than the west. In the extreme south the lower Morava Valley contains big stretches of unreclaimed marsh. Farther north the relief is broken by the spurs and outcrops of the White Carpathian foothills, notably the Čtítby Plateau. The valleys of two eastbank tributaries of the Morava, the Olsava and the Drevnice, provide the connections between Moravia and Slovakia.

Moravia is separated from the southern tip of Silesia by the broad pass known as the Moravian Gate (Moravská Brána). There the divide between the Bečva Valley, which is part of the Morava system, and the upper valley of the Oder, which flows north eventually to the Baltic, is low and easy. On the west side the low range of the Hercynian Jeseníky overhangs the Gate in a steep cliff. About six miles to the east the outermost flysch ranges of the Carpathians rise more gradually. The country both to east and west of the Gate is sufficiently rugged to explain the canalizing of movement through it over centuries of history.

In northernmost Moravia and Czech Silesia the most conspicuous physical feature is that of the coal deposits. East of Silesia there are no other substantial coal resources in Europe except those of the distant Donets Basin in the U.S.S.R. On the Carpathian side of the coalfield the poor country of the wooded flysch ridges has provided part of the emigrant labour force for the mines. On the northwestern side the rich loess soils of the lower Olza (Olsa) and Opava valleys provide a part of the food supply for a large established urban market.

**2. Climate.**—Throughout Czechoslovakia the influence of topography on climate is stronger than that of geographical location. The conditions of temperature and rainfall depend mainly on relief, and local variations are noticeable. In the Czech lands the sharpest contrasts are between the basin climates which tend to continental features (Prague, January  $-3^{\circ}\text{C}$  [ $26^{\circ}\text{F}$ ], July  $19.5^{\circ}\text{C}$  [ $67^{\circ}\text{F}$ ]) and those of the surrounding hills which are more moderate. In Slovakia the same kind of contrast is noticeable between the climates of the Alpine region and those of the Danube plains. There is a tendency to a slight increase in temperature range with a more easterly position, and to a summer maximum in rainfall. Prague, with a total rainfall of only 19 in. (483 mm.) illustrates the conspicuous dryness of inner Bohemia. Other noticeable climatic features are those of frequent fog (a hazard to aviation) in Bohemia and Moravia and the occurrence at 10- to 15-year intervals of violent and destructive storms in the Carpathians.

**3. Vegetation.**—The position of Czechoslovakia in Europe in part explains the wide range of its plant associations. The flora of eastern and western Europe, of the great plain of the north, and

of the Mediterranean are present. Moreover, the diversity of climatic conditions, arising from the broken relief, together with the varieties of soil, is faithfully reflected in the plant distributions.

A little more than one-third of the country is forest covered. In Bohemia and Moravia-Silesia the existing woodland is the result of years of competently managed forestry. The proportion of coniferous forest to the whole is high, more than two-thirds, and this is largely the result of replanting with a view to timber markets. Spruce, fir, larch, and Scots pine are the most usual species. In the bounding ranges to Bohemia there are still big beech forests, and in the sandstone area north of the Elbe are fine stands of oak. The Šumava ranges in southern Bohemia contain preserved areas of virgin forest. In Slovakia the proportion of deciduous forest is higher than in the west (just under half) and the predominant forest cover is beech (one-third). Managed forestry in Slovakia has neither so long a tradition nor so high a standard as it has in Bohemia: the actual forest cover therefore is much nearer the natural one than that in the west. The beech woods become especially impressive toward the frontier with Subcarpathian Ruthenia (the Transcarpathian Oblast of the U.S.S.R.). There they are compact and more exclusive of other species.

There is an alpine flora in Slovakia that is noticeably rich in the limestone areas. Dwarf moss campion, bird's-eye primrose, and creeping geum are found at great heights, together with edelweiss and some beautiful gentians. It is a different flora from that of the high moors of Bohemia, although both the Krkonoše Mountains and the White Carpathians have a very abundant and rather similar hill vegetation. In Bohemia, dwarf birch and knee pine are common. The high meadow flora of the Krkonoše in spring and early summer is especially brilliant with globeflower, Turks-cap lily, and anemone. In the White Carpathians the flysch ranges are marked with an abundance of broom in early summer, and later with beautiful bellflowers.

Both parts of the country at lower levels contain plants which are generally associated with steppe environments. In Bohemia soil distinctions account for some distributions. The limy soils favour cocksfoot grass, upright brome grass, and yarrow; the soils rich in humus have a good range of orchids. In central and southern Moravia are a number of halophytic plants; e.g., marsh samphire (*Salicornia herbacea*) and goosefoot. In lowland Slovakia, the *púšťa* vegetation appears with an abundance of fescue and feather grass. The north-south tectonic depression in the Carpathians, which lies roughly between the towns of Prešov and Košice, appears to be a plant frontier as well as a geological divide. The German botanist, F. Pax, at the end of the 19th century found a remarkable differentiation in the plant distribution on either side of it.

(H. G. S.)

**4. Animal Life.**—Czechoslovakian fauna includes among the larger mammals the bear, wolf, lynx, and wildcat in small numbers, while otter, badger, polecat, marten, and mink are more numerous. Red and roe deer and wild boar inhabit the forests; the reintroduced chamois is found in some mountain regions. Birds include golden and whitetailed eagles, osprey, griffon and Egyptian vultures, and eagle owls. Greylag geese and many marsh and water birds occur, as well as both black and white storks. The giant European catfish (or *Wels*) of the Danube, weighing 200 lb. or more, is outstanding among the many fish. Reptiles and amphibians are represented by European pond tortoises, several kinds of snakes and lizards, and many toads and frogs. (Ro. W. H.)

## II. GEOGRAPHICAL REGIONS

The traditional regions of the Czechoslovak republic are Bohemia, Moravia, Silesia, and Slovakia. Bohemia and Moravia-Silesia were long known as the Historic Provinces and somewhat resemble the French *pays* in their longstanding identity. Their distinction is partly a criterion of relief—the Bohemian Massif, the Moravian Basin and corridor, and the Slovak Carpathians—and partly one of language. Bohemia is almost wholly Czech-speaking, Slovakia is Slovak-speaking, and Moravia-Silesia includes both languages. There is also a distinction of tradition—the Historic Provinces were for centuries Austrian in orientation, while Slovakia was Hungarian. The structural regions described in *Physical Geography* above do not coincide with the traditional regions.

There are, in addition to the traditional regions, contemporary economic regions which are described as follows:

**West Bohemian Region.**—Plzeň (*q.v.*) is the capital of this area, which includes the Plzeň and Ohře basins with conspicuous coal and lignite resources. A group of established spa towns lies in the northwest.

**East Bohemian Region.**—This, with the capital of Hradec Krá-

lové (*q.v.*), includes the farming area of Polabí. There are textile and glass factories bordering the Krkonoše.

**North Bohemian Region.**—With Ústí nad Labem (*q.v.*) as its capital, this region has lignite mines west of Ústí. There are chemical works and glass factories; the farming neighbourhood of Žatec is renowned for its hops.

**South Bohemian Region.**—Centred on České Budějovice (*q.v.*), this area comprises the Šumava ranges and the two lake basins of Třeboň and České Budějovice. Forestry is important.

**North Moravian Region.**—The capital is Ostrava (*q.v.*) and some mining and manufacture are based on the southernmost measures of the Silesian coalfield. The region also includes the rich farming area around Olomouc.

**South Moravian Region.**—The capital Brno (*q.v.*) serves this productive and prosperous area, which has a wide variety of industry and good farming.

**West Slovak Region.**—Bratislava (*q.v.*) is the capital of this region of established farming on good soils and of expanding manufacture based on recent water power development as well as oil refineries.

**Central Slovak Region.**—With its capital at Banská Bystrica (*q.v.*), this area lies between the Liptov-Poprad Basin and the frontier with Hungary. Its wealth is in the mines of the Slovak Ore Mountains and in the forests. Manufacture in the 1960s was growing, mainly because of hydroelectric power development.

**Tatra Region.**—Rugged Alpine scenery has long attracted visitors to such established resorts as Štrbské Pleso (Štrba Lake), Starý Smokovec, and Tatranská Lomnica.

**East Slovak Region.**—This area, with Košice (*q.v.*) as its capital, is advancing in industrial production mainly because of water-power development.

In the Third Republic these regions have superseded those of tradition, although the major divisions are roughly in accordance with them. They were based on the planned use of resources in an authoritarian regime, and they cut across regions of structure, climate, vegetation, and soil. The precedent for this type of region was the pattern in the U.S.S.R. of geographic division based on the use of resources.

For the administrative regions, see *Administration and Social Conditions* below.

## III. THE PEOPLE

**1. Racial Characteristics.**—There is no distinctive physical type among the Czechoslovak people. In a territory which has experienced so much population movement, anthropological distinction would not be expected. The anthropologist Ales Hrdlička observed: "The original type is best preserved in parts of Moravia and Slovakia. It is a type characterized by good stature; strong, well proportioned body; mostly rounded head; face, medium or rounded rather than narrow and long; hair varying from blond to brunette, and eyes ranging from blue to medium brown; absence of prognathism." (*Czechoslovakia* edited by R. J. Kerner; University of California Press, 1945.) C. S. Coon's study of the races of Europe suggests a progressive change of cranial index from the dolichocephalic skulls of Bohemian pre-Christian grave material to the quite marked brachycephaly of modern times. There is, however, no consistent correlation between the development of a different cranial index and historical episode. In Slovakia slightly less stature and rather narrower head measurements are common. The minority groups are sometimes conspicuous; the surviving gypsies are markedly swarthy and have often narrower skulls and noses; the Magyars of the Slovak plains have on the whole broader, flatter faces than the Slovaks and concave noses are common. Frequent intermarriage between groups has made comments on physical distinctions somewhat pointless. Differences in temperament—the dourness of the Bohemian, the geniality of the Moravian, the quick emotions of the Slovak—have been reported by many observers.

Some past ethnographic distinctions remain in the gaiety and diversity of peasant costume, although this has vanished from daily use. Noticeable forms of it are in the Chod villages near the Bavarian frontier and in Slovak Moravia.

(Above) Štrbské Pleso (Štrba Lake); In the background are the peaks of the northwest Tatra Mountains. (Below) Pravčice Gate in the sandstone cliff formation near Hřensko, northern Bohemia

**2. Languages.**—Czechoslovak, a Slavonic tongue of the Aryan group, is the language of the republic. There is sufficient difference between Czech and Slovak to make the philology and literature of each something of a separate culture. (See CZECH LANGUAGE; SLOVAK LANGUAGE; CZECHOSLOVAK LITERATURE.) Bohemia is now almost wholly Czech-speaking although the German past of the peripheral highlands cannot be discarded completely from its cultural inheritance. Western Moravia is Czech-speaking, again with indelible traces of German settlement; eastern Moravia is Slovak-speaking. Some Hungarian is used on the southern borders of Slovakia, some Polish in the extreme northwest of Slovakia, but language and culture by the mid-20th century had become practically homogeneous throughout the republic. In south Moravia, near Mikulov, a curious group of Croat villages of obscure origin remains identifiable. In the Carpathians the spoken dialect is "Lach," mainly Czech in character but with Polish terms occurring frequently. Occasionally traces of a Vlach dialect appear in Beskydy (Beskid Mountains), suggesting a past connection with the Rumanian pastoral groups of the East Carpathians.

**3. Religion.**—The religion of a country with a Communist regime has no normal expression in statistics of church membership. In 1948 the majority of the population was ostensibly Roman Catholic. The minorities were Protestants (mainly in northeast Moravia and east-central Slovakia), the Greek Catholics of north-east Slovakia, and the adherents to the compromise institution of the National Church of Czechoslovakia founded in 1920. In parts of Bohemia, especially north and south of Plzeň, agnosticism has long been widespread and pronounced. Archbishop (later Cardinal) Josef Beran of Prague, primate of Czechoslovakia, was expelled from his see and interned from 1951 to 1963. Other bishops and priests were imprisoned or silenced but an edict of Oct. 2, 1963, removed restrictions on the personal liberty of the prelates. The courageous witness of many Roman Catholics in the face of atheistic Communism was possibly somewhat weakened in its effect by former associations of Roman Catholicism with Austrian repression. By the 1960s the churches in Czechoslovakia, as in all Communist countries, provided an unsolved problem. They seemed indestructible, but were divorced from public life and especially from education. Under the law of 1949 they are administered by a government bureau of ecclesiastical affairs and the state pays the salaries of ministers; religious instruction is provided in elementary schools for those wishing it. (H. G. S.)

#### IV. HISTORY

For the history of the Czechs before World War I see BOHEMIA; also MORAVIA. For the Slovaks see SLOVAKIA.

When World War I broke out in 1914 Czech and Slovak sympathies tended to be on the side of Russia and the Serbs and their western allies against the Central powers, while the Germans of Bohemia were zealous supporters of the Austro-Hungarian and German war effort. Both Czech and Slovak soldiers went over to the Russians in considerable numbers in the early days of the war. Many Czech civilians suspected of disloyalty to Austria were interned, and by 1916 several thousand had been shot. In May 1915 the eminent "Young Czech" leader and exponent of neo-Slavism, Karel Kramář, was arrested for high treason, and in July another Young Czech leader, Alois Rašín (*q.v.*), suffered the same fate: both were sentenced to death, but were not executed. Thus open political activity within the country came to an end.

Until the eve of the war, Kramář, like Tomáš Garrigue Masaryk (*q.v.*), had been loyal to Austria. Kramář had worked for an Austro-Russian alliance, while Masaryk was drawn toward the western democracies, but both men had hoped that the Austrian authorities would accept the fact that the majority of their subjects were Slavs and draw the—as it seemed to them—obvious conclusions. As soon, however, as Austria-Hungary was at war with Russia, Kramář began to think in terms of a Russian grand duke as king of the Czechs. Masaryk, who had little respect for tsarist Russia, happened to be in Switzerland toward the end of 1914. Learning that he would be arrested if he returned home he decided to remain abroad in order to present the Czech and Slovak

case to the Allies against what he regarded as the anachronism of Austria-Hungary. In London and Paris few people had any real knowledge of Austro-Hungarian affairs, and those who had were inclined to regard Austria-Hungary as a necessary structure which should not be disturbed and which might be drawn away from its German ally by conciliatory gestures: indignation in both Great Britain and France was concentrated against Germany.

**Czechoslovak Struggle for Independence.**—In the autumn of 1915 Masaryk was joined in Switzerland by Josef Dürich, a member of the conservative Czech Agrarian Party, and by the young Edvard Beneš (*q.v.*). It was decided that Dürich should go to Russia, that Beneš should join the Slovak patriot Milan Štefánik in Paris, while Masaryk himself proceeded to London.

On Nov. 14, 1915, a manifesto was issued, signed by Masaryk and Dürich, by the leaders of the Czech colonies in the Triple Entente states (France, Great Britain, and Russia), and notably also by the Czechs and Slovaks in the United States. This was the first public pronouncement by the Czechs abroad against Austria-Hungary and in favour of the Entente and of the independence of a Czech and Slovak state. In January 1916 a Czechoslovak foreign committee, which had been formed earlier, was transformed into the National Czechoslovak Council, with Masaryk as its president, Dürich as its vice-president, and Beneš as its secretary-general; the Slovak representative was Štefánik. Its first big success came on Jan. 10, 1917, when, having been asked by the U.S. president, Woodrow Wilson, for a statement of their war aims, the Allies included among them the liberation of the "Czecho-Slovaks."

At first Masaryk and Beneš had been able to communicate with the Czechs at home only through their secret organization, the Maffia, but the death of the Austrian emperor, Francis Joseph I, in November 1916 and the beginning of the Russian Revolution in March 1917 transformed the situation. Charles, the new emperor of Austria, put an end to the severe military regime to which the country had been subjected and recalled the *Reichsrat* in May 1917. The Czech deputies immediately demanded "a federal state of free national states with equal rights" and declared "before the whole world the Czech people's will to freedom and independence." Just before this, 222 Czech men of letters had signed a manifesto in favour of what they thus believed to be their national rights.

Though many Czech and Slovak prisoners in Russia were impatient to fight for their cause their hopes were constantly deferred until on July 2, 1917, they were at last able to fight in the Battle of Zborów in Galicia. By this time Russia was collapsing and it was important that the Czech troops should not be lost in the general confusion. Masaryk, who had left London for Russia in May 1917, managed to obtain recognition of the independence of the Czechoslovak forces in Russia in the following October, but the Bolshevik Revolution in November reopened the whole question. On Dec. 19, 1917, the French government agreed to the establishment of an independent Czechoslovak army on French soil and it was decided that the Czech and Slovak soldiers in Russia should be transferred across Siberia to France. In May 1918, probably thanks to German pressure, L. D. Trotsky, the Soviet commissar for war, issued an order for their disarmament, which, much against Masaryk's will, led to serious Czech-Russian hostilities. In these, however, the Czech legionaries were able to distinguish themselves. Meanwhile, after Italy's defeat at Caporetto in October 1917, the Italian government no longer blocked the aspirations of the Croats, Serbs, and Slovenes with whom the Czechs and Slovaks felt such strong solidarity. In April 1918 representatives of all the subject peoples of Austria-Hungary were invited to a congress in Rome and the Italian authorities agreed to the enrollment of Czech and Slovak prisoners of war in a Czechoslovak legion in Italy. By this time Masaryk estimated the Czechoslovak forces mobilized in the service of the Allies at 128,000 (92,000 in Russia, 12,000 in France, and 24,000 in Italy).

Masaryk left Russia in March 1918 in order to travel to the United States via Japan; he arrived in May. Through his American wife he had useful connections there, and, since President Wilson had begun to take the lead with the Fourteen Points (Jan. 8, 1918) in delineating the future peace settlement, it had become

and godless institution to the Slovak Catholics. When the quarrel was so far patched up as to allow Tiso to join the cabinet the Czechs had, however, begun to take steps to answer Hlinka's indictments. In the first place, the local government of the whole country was reorganized by a law passed in July 1927; in accordance with this law each of the four regions (Bohemia, Moravia, Slovakia, and Subcarpathian Ruthenia) was given restricted powers of self-administration through a president, vice-president, elected assembly, and executive committee of which two-thirds were elected, the remaining one-third being nominated by the government in Prague. Second, early in 1928 the Czechoslovak government reached a *modus vivendi* with the Vatican by which a satisfactory compromise was achieved over questions outstanding between church and state.

**4. Foreign Affairs.**—The foreign policy of the first Czechoslovak republic enjoyed the continuity, unusual in a democratic state, of being directed by the same person throughout its career. Beneš was the pupil of Masaryk and was foreign minister from 1918 until, on Dec. 18, 1935, he succeeded Masaryk as president. With his own successor, the historian Kamil Krofta, he continued to direct foreign affairs to the end. Masaryk-Beneš policy was essentially western in character; since Great Britain would make no continental alliances and France in the 1920s was eager to ally with the successor states, it was with France, on Jan. 25, 1924, that Czechoslovakia made its most important alliance. Beneš actively was a champion of the *status quo*, which he hoped to fortify by the extension of the power of the League of Nations—he was one of the most visible figures at Geneva in its heyday. The enemy of the peace treaties in central Europe was Hungary; it was to curb the revisionism of the Magyars that Beneš, by agreements first made in 1921 and 1922, allied himself with Rumania and Yugoslavia, both of which embodied much former Magyar territory. This alliance was always referred to as the Little Entente (*q.v.*). It should be added that the Slovaks, whose discontent was exploited by the Hungarians against the Czechs, were more violently anti-Magyar than the Czechs (it was they who had suffered from magyarization in the years before 1914); this was true for many years of the majority of the followers of Hlinka. The only obvious failure of Beneš as foreign minister was to be found in Czechoslovak relations with Poland. Apart from the fact that Czechs and Poles had squabbled for many years before, the Poles could never forgive the compromise by which the highly industrialized territory of Teschen (Těšín or Cieszyn) in Silesia had been divided between them on July 28, 1920.

Although Beneš was never popular in Germany he was not on bad terms with the rulers of the Weimar Republic. To some extent this facilitated the activist policy of the more moderate Sudeten German parties which began in 1926. Elections held toward the end of 1929 strengthened the Socialists, both Czech and German, once again; and a German Social Democrat, Ludwig Czech, became minister of social welfare under the new Czech Agrarian prime minister František Udržal, who was succeeded by Jan Malypetr in 1932.

**5. Rise of Nazism.**—The halcyon period of prosperous co-operation was gradually obscured by the great depression which culminated in 1931 in the collapse of the biggest Austrian and German banks upon which central and eastern European industry still largely depended. As the economic situation worsened, Hitlerism grew: it was a German-Austrian state of mind that was almost new in northern Germany but that had been alive among the Germans of Bohemia since 1848. There had been a German Workers Party in Bohemia before 1914 and it continued in Czechoslovakia after 1920 as a branch of Hitler's party in Bavaria; eight Nazi deputies were elected in 1929 by the Sudeten Germans to the Czechoslovak Parliament. The young Bohemian Nazis were formed into what was called the Volkssport organization, which sent its representatives to the Nazi Party rally at Nürnberg in 1929—indeed the Bohemian Nazis made it clear, as they had before 1914, that they aimed at the incorporation of large parts of the Czechoslovak republic in Germany. In 1932 seven members of the Volkssport were tried by the Czechs for conspiring against the republic and condemned in 1933 to a year or so of imprison-

ment. In October 1933 in order to forestall their official suppression the Sudeten German Nazi Party and also the Nationalist Party dissolved of their own accord. By this time Hitler had been chancellor of the German *Reich* for nine months, and the aggressive face of Nazi Germany exacerbated relations between the Czechs and the nationalist Sudeten Germans. The Socialist and Clerical Sudeten Germans, who were anti-Nazi, were still represented in the government, but they were regarded with suspicion from both sides and the number of their followers declined.

The situation was envenomed because the predominantly Sudeten German districts were highly industrialized and their industry was of the kind most vulnerable in a slump. Consequently the rate of unemployment was higher among the Germans than among the Czechs. Czech-German relations also suffered from the fact that the Sudeten Germans were concentrated in the fortified regions flanking the German frontiers. From 1933 the Czechs not unnaturally took refuge in special security measures in the frontier districts; this inevitably curtailed the liberties of the German-speaking population and, like their unemployment, was duly exploited by Nazi propaganda.

Urged on by the economic crisis and by *Reich*-German influences a number of persons began to canvass the political union of all the Sudeten Germans under the leadership of Konrad Henlein, a hitherto obscure bank clerk and gymnastics teacher. This movement was launched on Oct. 1, 1933, as the Sudetendeutsche Heimatfront and it soon became evident that the Nazis and Nationalists would reassemble within it. From the beginning of 1935 the Heimatfront (later called simply the Sudeten German Party) began to disseminate propaganda of a frankly Nazi and violently anti-Semitic kind in preparation for the Czechoslovak elections to be held on May 19 of that year. While declaring himself loyal to the Czechoslovak state, Henlein's attitude to democracy was more than dubious, and he insistently demanded a reversal of Czechoslovak foreign policy. Instead of support of the League of Nations and the French alliance and Little Entente, he asked for a reorientation toward Nazi Germany. It so happened that the elections in Czechoslovakia were immediately preceded by a treaty between Czechoslovakia and the U.S.S.R., a move in the opposite direction which the Nazis, in Germany and elsewhere, were able to interpret according to their purposes as the selling of Europe to Bolshevism. In point of fact the Czechs had first recognized the Soviet regime in the previous summer, and their treaty with the U.S.S.R. committed them only to join France if the French should decide to come to the help of the U.S.S.R. were it attacked.

When the voting took place in Czechoslovakia on May 19, 1935, there was little change among the Czechs, but 1,249,530 Sudeten Germans (nearly two-thirds of the Sudeten German population) voted for Henlein, whose Heimatfront thus became the biggest single party in the republic. For the moment Henlein and his friends restricted their demands to an ill-defined autonomy. In view of the revival of conscription in Germany (March 1935) and the whole Nazi trend, Beneš initiated his presidency by a drive toward strengthening Czechoslovak defense. After Hitler had remilitarized the Rhineland (March 1936) a Czechoslovak defense law was passed, and the country's fortifications were extended. At the same time the president determined to give more serious attention to valid Sudeten German grievances. It was clear that the German-speaking districts were largely, though not exclusively, administered by Czech officials and police, who spoke poor German and often ignored minority rights. Since Nov. 5, 1935, Hodža, a long-standing Slovak leader and a good linguist with many-sided connections, had been prime minister; he seemed a suitable person to embark upon conciliatory negotiations. On Feb. 18, 1937, an agreement was made by Hodža with the anti-Nazi Sudeten German leaders who still cooperated with the Czechoslovak government, an agreement by which the minority obligations of the latter were to be more generously implemented. In cooperating with Berlin, Henlein always rejected what the Czechs offered and demanded what they were bound to refuse; a climax seemed to be reached when at Karlovy Vary in April 1938 Henlein asserted the right of the Sudeten Germans to profess Hitler's national socialism as a

political faith, although it clearly ran counter to the democratic constitution of Czechoslovakia.

**6. The Runciman Mission and Munich Conference.**—Already on Nov. 5, 1937, Hitler had secretly informed his military leaders of his intention to seize Austria and Czechoslovakia (the two comprising a single unit in his plans) at the earliest opportunity, and on March 12, 1938, the Germans annexed Austria. This made the situation of Czechoslovakia precarious, and many of the non-Nazi Sudeten Germans quickly joined Henlein. From this time the Sudeten German Party redoubled its encouragement of the discontent of Hlinka and his followers in Slovakia and of all other groups within the republic which were in any degree hostile to Beneš and Hodža. Fearing a German attack at any moment, Beneš ordered a partial mobilization on May 20. Thereupon, on May 30, an aroused Hitler signed a secret directive for Czechoslovakia to be smashed by military action by Oct. 1, 1938, at the latest. In the mounting tension the British government sent a mission headed by Lord Runciman, who arrived in Prague on Aug. 3, to mediate between Henlein and the Czechoslovak government. Since Henlein had orders from Berlin not to come to terms, all negotiation became merely farcical. On Sept. 12, at the Nürnberg rally of the Nazi Party, Hitler delivered a furious attack upon Beneš, and on Sept. 15 Henlein with many of his followers fled to Germany; other Sudeten Germans, feeling that the Nazis had deceived them, rallied to Prague. At this point Hitler indirectly received most welcome British support when Neville Chamberlain flew to Germany to see him. He dealt with the British prime minister rather as Henlein had dealt with Hodža, and on Sept. 28 war seemed inevitable, with the western powers and the U.S.S.R. pledged to Czechoslovakia's aid. On Sept. 22 Gen. Jan Syrový, the inspector general of the Czechoslovak Army, had succeeded Hodža as prime minister, and the Czechs prepared for battle.

On Sept. 28, however, Chamberlain appealed to Mussolini who suggested a conference of the heads of the governments of Germany, Italy, Great Britain, and France. Without consulting the Czechs (or the U.S.S.R.), Hitler, Mussolini, Chamberlain, and Edouard Daladier signed an agreement at Munich early on Sept. 30, 1938, by which Czechoslovakia was forced to cede to Germany all those districts of Bohemia and Moravia which had had a 50% or more German-speaking population according to the Austrian census of 1910. The session had to be carried out by Oct. 10. In fact the German officers on the executive commissions annexed many other small sectors which they claimed as strategically necessary. Meanwhile, both Poland and Hungary had put in their claims. Teschen was ceded to the Poles without foreign intervention, but it was the German and Italian foreign ministers who drew the new frontiers between Slovakia and Hungary by the Vienna award of Nov. 2, 1938. Thus Czechoslovakia was deprived of about a third of its population, 3,576,719 inhabitants going to Germany, 992,496 to Hungary, and 230,282 to Poland. These figures included about 1,200,000 Czechs and Slovaks allotted to the neighbouring states with no minority rights at all. France and Great Britain made an ineffectual attempt to guarantee what was left of Czechoslovakia, but this only increased the bitterness felt against the west by the Czechs.

#### B. THE SECOND REPUBLIC AND THE GERMAN PROTECTORATE

Beneš resigned on Oct. 5 and left the country. German pressure permitted the Slovak and Ruthene autonomists to have their way and a federal Czecho-Slovakia, with a semi-independent Ruthenia attached to it, was established. The latter territory, with Father Augustin Volosin as premier, was advertised all through the autumn as the cradle of Ukrainian nationalism, but it was swallowed up by Hungary in March 1939 before it emerged from its initial chaos.

In Prague on Nov. 30, 1938, Emil Hácha, president of the supreme administrative court, was elected successor to Beneš. A new cabinet was appointed under the Agrarian Party leader Rudolf Beran, who had flirted with Henlein in order to make difficulties for Beneš; a pro-German diplomat, František Chvalkovský, was made foreign minister. In the future, it was stated, only two parties would be allowed, the Party of National Unity on the right and the Party of Labour on the left. The most powerful political

figure in the country was Ernst Kuntz, the leader of the then considerable and dominant German minority based on Prague.

**German Annexation.**—Hitler, who always intended to annex all Bohemia and Moravia, was merely annoyed by the delay caused by the Munich agreement. He ordered his agents to stir up both Slovaks and Ruthenes against the government in Prague, and he summoned Hácha and Chvalkovský to Berlin on March 14, 1939, where they were informed that Prague would immediately be destroyed from the air unless they surrendered the Czech territories to him. On March 15 the rump of Bohemia and Moravia, with the big Skoda armaments works, was occupied by the German Army, and Hitler appeared in Prague. On the following day he issued a decree by which the newly seized territories became a protectorate of the *Reich*. On April 5 Konstantin von Neurath arrived in Prague as *Reichsprotektor* accompanied by Karl Hermann Frank, the most threatening of the Sudeten German leaders, as state secretary.

**World War II.**—At the outbreak of hostilities a conference was held in Neurath's office on Oct. 9, 1939. The Germans decided upon a policy by which the Czech intellectuals and others who resisted the Nazis should be liquidated, but the rest were to be assimilated, chiefly by sending them to work in Germany. The Czech army was already disbanded. A student demonstration three weeks later caused the Germans to suppress all higher and secondary education for Czechs. When Hitler attacked the Soviet Union in June 1941 the Czechs, although the German police gave them little scope, were obviously restless. Thereupon in September Neurath was replaced by Heinrich Himmler's right-hand man, Reinhard Heydrich, notorious for his cruelty. Summary courts under German Gestapo presidents were set up, and hundreds of Czechs were condemned to death or sent to concentration camps.

Meanwhile Beneš and Masaryk's son Jan, with most of the former leaders, had established themselves as a provisional government in London. In July 1941 Great Britain and the U.S.S.R. accorded them full recognition. With British help it proved possible to murder Heydrich on May 27, 1942. The Nazis retaliated with savage mass executions. On June 10 they killed all the adult male inhabitants in the village of Lidice (*q.v.*) and razed it; the women were sent to concentration camps, and the children disappeared.

For the next two years there was little change; the Czechs reaped some comfort from the news that Beneš was in Moscow in December 1943; on Dec. 12 he signed a Czechoslovak-Soviet treaty of alliance for 20 years. During the first half of 1944 the Soviet armies, with some Czechoslovak contingents, pushed forward into Ruthenia. A Czechoslovak brigade and three air force squadrons were serving with the British also.

In spite of the unprecedented prosperity which the Germans had allowed "independent" Slovakia to enjoy, they became ever more unpopular among the Slovaks as the war progressed. A Slovak rising against the Germans began at Banská Bystrica on Aug. 28, 1944, and continued until the end of October, but the Russians arrived too late to save the Slovak partisans, who had been joined by many Czechs, from the Germans. From the beginning of 1945 the Soviet armies advanced more speedily. In March, Beneš left London and, traveling via Moscow, was able to establish a provisional Czechoslovak government at Košice in Slovakia on April 3. Next day Bratislava fell to the Russians. On May 4 the population of Prague began to demonstrate against the Germans, whose general in command there capitulated on May 8. The Russians arrived in Prague on May 11, Beneš on May 16.

#### C. THE THIRD REPUBLIC

While still at Košice, Beneš appointed a provisional government with Zdeněk Fierlinger (a former diplomat and a left-wing Socialist with pro-Soviet views) as premier. His cabinet consisted of seven Communists (of whom three were Slovaks), two other Socialists, three Czech National Socialists, three Czech Populists, and three Slovak Democrats, together with Jan Masaryk as foreign minister and Gen. Ludvík Svoboda as defense minister. The defense minister had Communist sympathies, but more significant

was the nomination of the Communist Václav Nosek to be minister of the interior, with control of the police. A special commission was set up for autonomous Slovakia.

At Košice also, Beneš and Fierlinger worked out a general program based roughly upon a highly socialized economy and a "national state" without privileged minorities. On the government's return to Prague the most important requirements of the Košice program were carried out by decree, in particular by the decrees of Oct. 24, 1945, which nationalized the key industries and banking. A proclamation of June 18, 1945, announced that Germans and Magyars who could not prove that they had been active anti-Fascists before or during the war were to be expelled; the United States, British, and Soviet governments approved this decision at Potsdam on Aug. 2, 1945. By the end of 1946 the mass of the Germans had fled or were deported; after this the 165,000 who remained were absorbed as Czechoslovak citizens. The Košice program also emphasized the Soviet alliance. In June 1945 the Poles, under Soviet pressure, restored to the Czechs that part of Teschen which had changed hands in October 1938; on June 29, 1945, it was announced in return that Subcarpathian Ruthenia had become a part of the Ukrainian Soviet Socialist Republic. The formerly Sudeten German areas were colonized by Czech and Slovak peasants. These changes altered the nature of the Czechoslovak state. The Czechs henceforth composed more than 66% of the population, and the Slovaks, whose birthrate was higher, formed 28% of it in 1958.

A provisional assembly elected by local anti-Fascist committees, which had formed as the country was liberated, met on Oct. 28, 1945, and functioned until a Constituent Assembly was elected on May 26, 1946. The five chief parties then polled approximately as follows: Communists 2,700,000; Czech National Socialists 1,300,000; Populists 1,100,000; Slovak Democrats 988,000; and Social Democrats 906,000. A new government was appointed with the Communist leader Klement Gottwald as prime minister.

The first big measure put to the assembly was an economic plan for 1947-48. The offer of aid from the United States under the European Recovery Program in June 1947 was of great interest to the Prague government, which, however, was informed by the Soviet government that for the Czechs to discuss the U.S. project would be incompatible with their alliance with the U.S.S.R. There was much indignation over this Soviet veto, and opinion veered away from the Communists, so that the situation grew increasingly tense. Within the cabinet a conflict developed over the action of Nosek in substituting Communists for non-Communists in the police force. On Feb. 20, 1948, 11 anti-Communist ministers resigned in protest. The Communists thereupon called up police reserves from outside Prague and their own action committees, chiefly trade union members: newspapers hostile to them were suppressed, student demonstrations crushed, and many people arrested. On Feb. 25 Beneš gave way and accepted a new Gottwald cabinet without anti-Communists. Jan Masaryk, who had remained at the Foreign Office, was found dead in the courtyard beneath his window on March 10—it was strongly suspected that he had been murdered, though it was made to appear that he had killed himself. He was succeeded by his Communist deputy, Vladimir Clementis, a Slovak.

On March 2, 1948, the Slovak commission in Bratislava was purged, and Slovakia was subjected to Prague. On April 18 the Social Democrats, the last major party to survive, merged with the Communists. In the elections held on May 30 for a National Assembly, the voters had no choice between voting for a National Front which polled 6,400,000 votes and spoiling their papers—as 1,573,000 persons did. The new constitution, establishing a "people's democracy," had been unanimously accepted by the Constituent Assembly on May 9, but Beneš refused to sign it. He resigned on June 7 and died three months later. The constitution was immediately ratified by the new president, Gottwald, who was succeeded as premier by Antonin Zápotocký, with Rudolf Slanský, secretary-general of the Communist Party, as vice-premier.

In 1949 relations between the regime and the Roman Catholic Church became strained, and the archbishop of Prague, Josef Beran, was interned. A five-year plan was launched to run from

January 1949 to the end of 1953. As its aims were raised in 1951, the difficulties became manifold and the hunt for scapegoats steadily intensified. Clementis, who had been in London during the war, was disgraced and arrested toward the end of 1950. A greater impression was made when Slanský, a trained Muscovite, was arrested in November 1951, and the political trials seemed to culminate in that of Slanský and his associates in November 1952. After particularly abject confessions, Slanský, Clementis, and nine others were condemned to death. On March 14, 1953, Gottwald died and was succeeded by Zápotocký, with the Slovak Vilem Široký as the new prime minister. The currency reform of May 30, 1953, reduced real wages drastically and led to serious riots, particularly at Plzeň (Pilsen). Zápotocký died on Nov. 13, 1957, and was succeeded by Antonin Novotný, first secretary of the Communist Party. On July 11, 1960, a new constitution was promulgated.

The principal preoccupation of the country's leaders in the early 1960s was how to stop the general worsening of the national economy. Though Czechoslovakia had become the Soviet bloc's chief supplier of engineering products and was furnishing industrial goods and, notably, armaments to the underdeveloped countries of Asia and Africa, the growth rate of production was unsatisfactory. Protest marches against the regime, its foreign aid programs (20% of the Soviet bloc's total), and its alliance with the U.S.S.R. took place in 1963.

Czechoslovakia meanwhile had lagged behind other Communist states in the process of "destalinization," though concessions to Slovakia (*q.v.*) were made from 1956. In August 1963, however, Slanský was posthumously absolved of the criminal charges of treason and espionage for which he had been condemned, though he was still held guilty of "antiparty" activity. Next, on Sept. 20, 1963, Široký was expelled from the Presidium of the Central Committee of the Communist Party and dismissed, with other ministers, from the government. His place as prime minister was taken by Jozef Lenárt, previously chairman of the Slovak National Council. Archbishop Beran was released from internment a fortnight later but was not permitted to resume his functions. (In 1965, after he had gone to Rome on being created cardinal, he was not permitted to return home.) In the National Assembly elections of June 14, 1964, there was still only one candidate for each of the 300 seats, but more than 140 were newcomers.

Some economic recovery was discernible at the end of 1964, and in January 1965 the Central Committee adopted a project for a more flexible system of economic planning, with a relaxation of bureaucratic control over managements. Discussed by the 13th congress of the Communist Party (May 31-June 4, 1966), this project came into effect on Jan. 1, 1967. Politically the 13th congress made no significant changes in the leadership of the party, Novotný remaining first secretary. The party had 1,698,000 members (including candidate members) in 1966.

While its relations with France were improving steadily (from 1964), the Czechoslovak government received coldly the German Federal Republic's peace note of March 25, 1966. The note had declared that the Munich Agreement of 1938 had been scrapped by Hitler and could no longer form the basis of any territorial claims by Germany. Czechoslovakia's reply (May 6), besides criticizing the Federal Republic's attitude to the German Democratic Republic and to the German-Polish frontier question, demanded that the Federal Republic acknowledge the Munich Agreement to have been invalid from its inception—thereby prejudicing any legal claims which might have been made on behalf of Sudeten Germans dispossessed after World War II. In January 1967, however, when representatives of the Federal Republic's new government went to Prague for talks, it seemed that the Czechoslovaks might take a less rigid line if the Federal Republic would guarantee the postwar frontiers. (E. Wi.; X.)

## V. POPULATION

The movement of population within the Czechoslovak settlement area became conspicuous long before the formation of the republic in 1918. Within the Austrian Empire, migration in Bohemia and Moravia-Silesia took several forms. One was a steady growth

(Left) Iron and steelworks at Kladno. (Above) Gottwaldov, centre of the Czechoslovak footwear industry. (Below left) Lipno Dam on the upper Vltava, southern Bohemia. (Below right) Production of isotopes at the atomic reactor in Řež

(LEFT) THREE LIONS, (ABOVE AND BELOW LEFT) ŽTK FROM CZECHOSLOVAK NEWS AGENCY, (BELOW RIGHT) EASTFOTO

of urban settlement based on manufacture and trade, giving the Czechoslovaks a lead over other Slavonic peoples and exemplified by the expansion of Prague, Plzeň (Pilsen), Brno (Brünn), and Olomouc (Olmütz). Rural population was densest in Polabí, around Žatec (Saaz) in Bohemia, and in the Haná lowlands on the Morava River. Considerable emigration took place to Vienna, the Vienna Basin, and the United States. In Slovakia, by contrast, there was a movement right out of the Carpathians, the Slovak peasantry going mainly to the New World and to a lesser extent as an immigrant proletariat to Budapest. Bratislava (Pressburg) remained largely a German and Magyar city.

Although the new republic spoke of "Czechoslovaks," combining Czechs and Slovaks in the 1921 and 1930 censuses, the two Slavonic majority peoples were far from identical. Moreover, more than one-third of the population were national minorities, chiefly Germans (23.4% in 1921) and Magyars (5.6%). The Czechs outnumbered the Slovaks by about three to one. The Czechoslovak state restored in 1945 lost about 798,000 people (mainly Ruthenes) from the cession of Subcarpathian Ruthenia to the U.S.S.R. (See TRANS-CARPATHIAN OBLAST.) Violent death and deportation during World War II accounted for most of the Jews, of whom there had been more than 200,000 at the 1930 census. A much larger diminution was caused by the expulsion of about 3,250,000 Germans, chiefly from Bohemia and Moravia-Silesia, in fulfillment of the Potsdam agreement of Aug. 2, 1945. The population in 1938 (excluding Subcarpathian Ruthenia) was estimated at 14,609,102. In 1950 it was 12,338,450 and in 1961 was 13,745,577; but the net decrease after 1938 was offset by the much more homogeneous population. In 1961, 94% of the people were Czechoslovaks (66% Czech, 28.0% Slovak). In 1958 the birth rate at 16.0 per 1,000 was slightly below that of the years 1935-39 (average 17.1);

the death rate was 9.7 per 1,000. The birth rate in Slovakia, however, was 22.3 per 1,000.

After World War II the main population movements were caused by attempts to fill the vacuum left by the expelled Germans and by an eastward migration into Slovakia associated with industry based on developing hydroelectric power. A secondary movement was from southern and northeastern Slovakia toward the expanding mining activity in Silesia. In 1961 Czechoslovakia had 119 towns with more than 10,000 inhabitants. The chief cities were the capital Prague (998,493), Brno (323,309), Bratislava (257,856), Ostrava (264,278), and Plzeň (141,583). Other major towns were Košice, Olomouc, and Liberec. (H. G. S.)

## VI. ADMINISTRATION AND SOCIAL CONDITIONS

**1. Constitution.**—After World War II the earlier constitution was abandoned and replaced on June 9, 1948, by a Soviet-style constitution proclaiming that the Czechoslovak People's Democracy consisted of two fraternal nations: Czech and Slovak. The single National Assembly (*Narodní Shromáždění*) of 368 deputies was elected for six years; a Presidium of 24 members remained in office when the National Assembly was in recess. The president, not less than 35 years old, was elected by the assembly for seven years; his powers were comparatively wide and he was also commander in chief of the armed forces. Technically in Slovakia there was a form of autonomous government consisting of a Slovak National Council (*Slovenská Národná Rada*) of 104 deputies, serving for six years, and a Board of Commissioners. After the 1948 *coup d'état* (see *History* above) elections became largely formalities.

The constitution adopted in 1960 proclaimed the "chief force of society and the state" to be the leadership of the working class

by the Communist Party of Czechoslovakia. A National Assembly of 300 members, elected for four years from a single list of candidates chosen by the Communist-controlled National Front, elects a Presidium of 30 to direct affairs between sessions. The president, shorn of the right of veto and of the right to dissolve the assembly, is elected for a five-year term as head of state. In Slovakia administration is by the Slovak National Council, elected for four years and with its seat at Bratislava. Regional and district government is by local national committees, elected for four years, relying on the participation of the inhabitants and guided by the state economic plan. The constitution laid down that education and cultural policy should be "carried out in the spirit of scientific Marxism-Leninism" and it limited personal ownership to "consumer goods" and "savings acquired through work."

**2. Regional Organization.**—The old provinces were in 1948 replaced by 19 regions (*kraje*), of which 13 were in the České Země or Czech Lands (Bohemia and Moravia-Silesia) and 6 in Slovakia, containing about 200 districts (*okresy*). In 1960 the

Administrative Divisions

\*Population is *de jure*. †1 sq. mi. = 2.6 sq. km. ‡The capital, Prague, forms a separate administrative unit with a status equivalent to a region.

regions administered by regional national committees (*narodní výbor*) were reduced to 10 (see Table).

**3. Education.**—In the Czechoslovak Lands, school attendance between ages 6 and 14 was compulsory after 1869. The Austrian system of education was of a high standard, but in Slovakia education was neglected by the Hungarians and great efforts were made by the Czechoslovak republic to fight illiteracy there.

Education is government-controlled and free up to and including university level. By the middle 1960s there were 7,260 nursery schools with 317,200 pupils; 11,800 basic nine-year schools with about 2,259,700 pupils; 385 general secondary schools with 105,000 pupils; and 680 vocational secondary schools with 302,000 pupils.

Before World War II there were two Czech universities—the famous Charles (Karlova) University at Prague, founded in 1348, and Masaryk (renamed Purkyně) University founded at Brno in 1919—also the Slovak University, Comenius (Komenského) founded in 1919 at Bratislava, and the German University at Prague. After World War II the German University was closed, the Czech Palacký (Palackého) University was reopened at Olomouc in 1946, and the Slovak Šafařík University was founded in 1959 at Košice. By the 1960s there were also technical colleges at Prague, Plzeň, Liberec, Pardubice, Brno, Bratislava, and Košice; a college of mining and metallurgy at Ostrava; agricultural colleges at Prague, Brno, and Nitra; and a college of forestry at Zvoleň. There were in all almost 50 institutions of higher education with 142,000 students and a teaching staff of 13,700.

**4. Health and Social Insurance.**—There were, in the middle 1960s, about 250 hospitals with 109,500 beds, 50 tuberculosis sanatoria and mental hospitals, and more than 2,500 health centres. The number of doctors doubled after 1937, to about 25,000.

Social security was reorganized in 1948 by the National Insurance Act which guaranteed to all citizens the right to support in old age, illness, and disability. Extensive changes were made under the Act of 1956. In addition to old-age pensions and health insurance of all employees, workers, and members of the armed forces, provision was made for pensioners in case of illness and

for other aspects of social protection; e.g., care for persons with diminished working capacity.

The administration of the health insurance of workers is entrusted to the trade unions and to the Central Union of Producers' Cooperatives for its members. Social security is entrusted to the State Social Security Board. Health insurance benefits include treatment in hospitals and spas, cash benefits, and family allowances.

To be eligible for an old-age pension the insured person must have been employed 20 years and have reached the age of 60 (for women 55). Pension benefits are compiled on the basis of length of employment, average monthly earnings for the last 5 to 10 years of employment, and the employment category. After reaching 65 years (for women 60) the employee who continues to work receives a full old-age pension in addition to earnings.

The trade unions organize low-cost vacations for their members in various recreation centres.

**5. Justice.**—The Penal Code (revised in 1957) is similar to that of the U.S.S.R. Serious crimes are tried in the state courts and lesser offenses by local committees. The code provides heavier penalties for crimes against the state or state property than for those against individuals. Punishments include the death penalty, imprisonment, loss of civil rights, confiscation of property, and fines.

**6. Defense.**—In the first republic, military service was compulsory at age 20 and lasted for 2 years. During the crisis provoked by Germany in 1938, the Czechoslovak Army, which was considered a fine and well-trained force, never received the order to fight and after March 15, 1939, was disbanded; its armament fell into German hands. A number of Czechoslovak units fought with the Allied armies and air forces in World War II.

After the war, the Czechoslovak armed forces were reorganized on the Soviet model, being divided into the army, air force, anti-aircraft defense, and forces of the interior. The last-named were subdivided into frontier guards and security troops. The two-year compulsory military service was maintained, and in 1952 the age of conscription was lowered to 19 years. In the mid-1960s the strength of the army was estimated at 14 divisions and of the air force at 700 tactical aircraft. Czechoslovakia is a member of the Warsaw Treaty Organization (q.v.) which created a supreme command for the armed forces of the U.S.S.R. and its European satellite states.

(K. Sm.)

## VII. THE ECONOMY

The Czechs have long excelled among the Slavonic groups in the quality and vigour of their industrial production. In the 14th century, the golden age of medieval Bohemia, and again from the early 19th century onward, their manufacturing and trading competence stood out. It derived in the 19th century from the coal of Silesia and Plzeň, the lignite of the northwest, and the iron of Slovakia. It was also based on wealth which attracted labour and developed metallurgy and chemistry. Besides silver and gold, the resources included copper and graphite, quartz for Bohemian glass, and kaolin for porcelain. There also exists a wealth of timber and considerable farming possibilities on the lowland soils.

Before World War II the discrepancy between the Czechs and Slovaks in production and trade was conspicuous. The Czechs, more numerous, better educated, and with more capital, were the moving economic force. Within the Austrian Empire a wide range of manufacture and trade flourished in which, by 1914, Czech managerial and banking competence were plain. Between the two wars, when foreign markets were contracting, the Czechs sought to export goods embodying special skills: glass, jewelry, precision instruments, leather goods. They could not, however, maintain the earlier Hungarian investment in and development of Slovak mining. Also between the wars the remarkable footwear factory of the Bat'a family at Zlín (modern Gottwaldov) formed the nucleus of the present large state enterprise. During the German occupation the economy was substantially disrupted and the natural resources were ruthlessly exploited with little regard to renewal of potential. The postwar phase was distinguished by large-scale nationalization, by a vigorous industrial development in Slovakia,

CTK—CZECHOSLOVAK NEWS AGENCY

(LEFT) HAYFIELD IN CENTRAL BOHEMIA; IN THE BACKGROUND ARE THE RUINS OF THE 14TH-CENTURY HAZMBURK CASTLE. (RIGHT) GRAIN HARVESTING IN THE HANÁ AREA OF SOUTH MORAVIA

and by a resumption of a wide range of manufactures. It was stimulated and indeed strained by the demands from eastern Europe and from farther afield by countries willing to trade with the Communist bloc.

The main feature of the manufacturing economy is the import of many raw materials—iron ore, oil, coal, material for the chemical industries, raw cotton, wool, and many foodstuffs. The chief exports are machinery, factory equipment in complete units, machine tools, chemical products, textiles, shoes, and glassware. By the 1960s signs of strain were beginning to appear in the form of decreased production rates in many segments of industry. Recognition of the liabilities attached to rigid and centralized planning with little heed to consumer interest appeared in the innovations of Prime Minister J. Lenárt's regime. The importance of quality as well as of production quotas and the noting of consumer tastes were taking the economy away from the initial strait-jacketed pattern which, indeed, was inconsistent with the independent shrewdness of Czechoslovak traditions.

The most noticeable rural postwar development was the nationalization of farming and forestry. Sugar beet and hops remain of substantial industrial importance both for home and export markets. In southern Slovakia increased attention is devoted to maize (corn) and tobacco growing and to pig farming.

The severest strain has been on the labour force. The expulsion of the Germans meant the loss of many highly skilled workers to the country, and the burden, upon the Czechs in particular, has been heavy, especially in forestry and the timber industries.

Industrial concerns with more than 500 employees were nationalized in October 1945 and those with more than 50 in April 1948. By the end of 1948, 96% of industrial employees belonged to the "socialized sector." Following a two-year reconstruction plan begun in 1947, industrial development was directed by a series of five-year plans on the Soviet model, with emphasis chiefly on the industrialization of Slovakia and on increasing output from the heavy industry and engineering sectors. By the middle 1960s industrial employees exceeded 2,500,000. However, the overall picture was of an active and skilled population, its urban and manufacturing element dominant, engaged to the limits of its capacity in satisfying home and export needs.

The 1961-65 plan was suspended in 1962 as impractical. By 1965 there was an attempt to break away from the "cult of the plan" and as an experiment certain aspects of capitalism such as price mechanism, wage incentive, and market competition were reintroduced. (H. G. S.)

**1. Agriculture and Forestry.**—In the middle 1960s about 56% of the land was devoted to farming including 40% of the arable. The best lowland soils are allotted to sugar beets, wheat, hops, and barley. Pig rearing is also associated with these regions of good arable farm land, the production of pork being much greater than that of beef. On the higher and poorer soils rye, oats,

and potatoes are the main crops. Beef and dairy cattle are kept throughout the republic. Sheep are raised chiefly in Slovakia. The professed aim of the Communist government is the collectivization of agriculture, involving a transition from small-scale peasant farming to modern large-scale methods. By the middle 1960s there were more than 7,500 agricultural cooperatives farming about 70% of all farm land; cooperatives and state farms together held approximately 90% of all farm land.

The losses to agricultural production because of ideological insistence on collective and state structures appeared to have been considerable. It seemed unlikely, however, that official reconsideration in the mid-1960s of conventional Marxist objectives in economic practice would bring about any resumption of pre-war prosperous family farming.

With forests covering about 34% of its area, Czechoslovakia, which is one of the few European countries with a rough balance between forested extent and timber requirements, ranks among the more richly wooded countries of Europe. Forests are owned and managed by the state; in the early 1960s the areas reafforested averaged 370 sq.mi. (958 sq.km.) annually. (See also *Vegetation* above.)

**2. Mining.**—Bituminous coal is obtained chiefly from Ostrava and Karviná in Silesia, but the supply of coking coal for steel-making is limited. Lignite is obtained chiefly around Sokolov, Most, and Chomutov in northwest Bohemia; these beds are among the best in central Europe. Iron ore is largely obtained in the eastern ranges of the Slovak Ore Mountains to the southeast of the Low Tatra, together with some copper, lead, antimony, salt, and gypsum. Lead, copper, and tungsten in limited quantities as well as pitchblende are mined in northwest Bohemia. Jáchymov (formerly Joachimsthal) was for centuries a source of silver and later became important as a source of uranium. By the middle 1960s the bituminous coal output exceeded 28,000,000 metric tons annually and lignite 70,000,000. Czechoslovak production of petroleum is inconsiderable. An agreement made at the end of 1959 between the U.S.S.R. and other countries of the Soviet bloc included provision for the supply of oil from the Volga fields to Czechoslovakia and Hungary by a pipeline through Uzhgorod (U.S.S.R.) and Bratislava, completed after 1963.

**3. Power and Industry.**—Most power stations in Czechoslovakia depend upon coal or lignite but by the 1960s there had been substantial development of hydroelectric resources, particularly in Slovakia. The power output in million kilowatt-hours approached 30,000, compared with 12,363 in 1953. In the postwar period more than 30 dams were completed: these include the series of constructions on the Vltava River known as the "Vltava Cascade" of which the Orlik Dam is the most notable.

Iron and steel are produced in Bohemia at Kladno, Chomutov, Plzeň, and in the Prague district; and at Ostrava, Vítkovice, Trinec, and Kuncice in Silesia. The national output of pig iron

in the middle 1960s exceeded 5,000,000 metric tons and of crude steel 7,500,000 metric tons. Textiles, clothing, and leather are produced mainly in Brno, Prague, Bratislava, Gottwaldov, and in northern Bohemia. Jablonec nad Nisou, Teplice, Ústí nad Labem, and Karlovy Vary are the chief centres for glassware and ceramics. Heavy machinery and machine tools are made at Plzeň (site of the Skoda armament works), Prague, Brno, Bratislava, Gottwaldov, and Ostrava; chemicals are produced at Prague, Bratislava, and in the Ostrava district.

**4. Trade and Finance.**—In 1937 the U.S.S.R. supplied 1.1% of Czechoslovak imports and took 0.8% of exports, but by the 1960s more than one-third of the imports came from the U.S.S.R., which also took almost the same proportion of Czechoslovak exports. In general, the greatest volume (about 70%) of foreign trade, which is a state monopoly, was with the U.S.S.R. and the people's democracies (German Democratic Republic, Poland, Hungary, and Rumania). Main exports were engineering equipment and machinery; main imports fuels, raw materials, and foodstuffs. After 1950 statistics of foreign trade were based on accounts of those 18 trade corporations to which the state monopoly in foreign trade was entrusted. The value of imports and exports is that at the frontier of the delivering country.

The whole internal trade network—wholesale and retail, including public catering establishments—is also state-controlled. In the middle 1960s there were more than 65,000 retail shops selling food and consumer goods, the great majority of which belonged to the "socialist sector" and were administered by the ministry of internal trade or by the Central Union of Consumers' Cooperatives. Prices are fixed by the government which thus directly controls the consumption.

The first republic established an early equilibrium of state finances and a stable currency with the Czechoslovak crown (koruna) at about U.S. \$1 = 33.3 koruny. The world depression compelled devaluation effecting a total depreciation of 30%, but the monetary position remained sound. During the German occupation more than one-quarter of the total production was taken by Germany and paid for with worthless bonds. After World War II the Czechoslovak government found a note circulation of more than 20 times that of 1938. There developed an inflation which was drastically cured by a "monetary reform" that deliberately annulled the value of cash savings. On May 30, 1953, the koruna was pegged to the Soviet ruble at 1.80 koruny = 1.00 ruble, com-

pared with the previous rate of 12.50 koruny = 1.00 ruble. In the mid-1960s the koruna rate of exchange was 20.10 for £1 sterling, 7.20 for U.S. \$1, and 8 for 1 new Soviet ruble.

Public finance is of the Soviet type, most capital for industry being provided through the budget; almost two-thirds of the expenditure is earmarked for investment in the national economy. By the middle 1960s both the revenue and expenditure exceeded 130,000,000,000 koruny. More than 86% of the revenue consisted of dividends from profits of the nationalized industries and trade; only about 11% came from taxes paid by the citizens. Over half the expenditure was earmarked for investment in the national economy; almost two-fifths went to the cultural and social expenses; only 9% (officially) of the budget was spent on national defense and public security. All the banking and insurance is nationalized. (K. Sm.; X.)

**5. Transport and Communications.**—As a landlocked country in the heart of Europe Czechoslovakia's communication system has significance for much of the continent. The railways from Vienna and Budapest to Leipzig, Berlin, and Warsaw go through Czechoslovakia. The Czechoslovaks own and exploit considerable sections of the Elbe and Danube (*qq.v.*) international waterways. All transport facilities are nationalized. Rail and road communications in Bohemia radiate from Prague, forming a pattern that has demanded some skill in engineering because of the gorgelike nature of the valleys converging on Prague. The Moravian lowland carries trunk routes between western Hungary, the Vienna Basin, and Silesia, with Brno as a nodal point. Railways cross the North Carpathians to Poland by the Jablunkov Pass and by the Poprad Valley. The Váh Valley in the Carpathians forms the main passage to the Danube plains. The total route mileage of railway in Czechoslovakia is 8,180 mi. (13,165 km.).

Since World War II the chief links of Czechoslovakia have been with eastern Europe where the preoccupation has been with air transport. Prague (Ruzyne Airport), in particular, has become one of the main airline centres of central Europe.

The double orientation of Czechoslovakia is apparent in the pattern of its waterways, the importance of which rests in part on the landlocked character of the country. The rapid and winding courses of many Bohemian waterways, and of the Váh and Hron rivers in Slovakia, limit their usefulness to rafting timber. The convergence of rafting streams on the Vltava above Prague made a considerable timber port of the city. The upper Elbe is navigable for small craft up to Mělník, at its point of confluence with the Vltava; the Vltava in turn is navigable as far as Štěchovice, about 16 mi. (26 km.) above Prague. For about 107 mi. (172 km.) the Danube forms the southern frontier to Slovakia. By the 1960s river traffic—chiefly of long-distance bulky freight (timber, corn, building material, gasoline)—had steadily increased.

Radio, television, telephone, and telegraph services are government monopolies.

**CZECHOSLOVAK LITERATURE.** The beginnings of vernacular writing in what is now Czechoslovakia are connected with the mission sent to Moravia in 863 by the Byzantine emperor Michael III at the request of Prince Rostislav. Christianity had reached the Slavs of Moravia from the west under the political aegis of the Frankish empire; in order to counter Frankish (i.e., German) influence Rostislav, prince of Great Moravia, sought "a bishop and teacher" from the Byzantine east. The mission was led by an experienced scholar and diplomat, Constantine (better known as Cyril), and his brother Methodius. The brothers translated the greater part of the Scriptures and the essential liturgical texts into a Slavonic literary language of Cyril's devising, based on the Slavonic vernacular of his native Salonika but enriched from other sources, notably Greek and the Slavonic of Moravia. The most notable literary monuments of this language (now known as Old Church Slavonic) are the *Lives* of the two brothers which were almost certainly written before 900, though they are preserved only in later copies. It is not known for certain whether these texts were written in the territory where the brothers carried on their mission; but other Church Slavonic texts can be assigned to the Czech area, notably the probably 10th-century *Legends* about St. Wenceslas (Václav, prince of Bohemia, 920-929) and his grandmother Ludmila. Similar hagiographical works in Latin from this period bear witness to a notable level of literary culture in the monastic centres of the early Bohemian state.

The Old Church Slavonic language ceased to be used after 1097 when Latin was established as the liturgical language of the country.

#### CZECH LITERATURE

The earliest preserved texts in the Czech language (other than isolated words and sentences) date from the latter part of the 13th century. Hymns from this period, though of unpretentious style, are accomplished in language and versification. The courts of the Přemyslide kings Václav I (1230-53) and Otakar II (1253-78) gave encouragement to courtly literature in German; but there is no certain evidence of a significant body of literature in Czech before the end of the century.

**The 14th Century.**—The 14th century saw a continuous stream of Czech literary production, including the epic, the lyric and the drama, as well as historical, religious and didactic works in prose. A group of verse *Legends*, written in the first quarter of the century, is the work of a single author or of a close-knit school, and already shows considerable maturity of technique. The earliest secular work is the epic *Alexandreis*, a life of Alexander the Great in octosyllabic couplets based on Gautier de Châtillon's Latin poem, and showing contact with the German Alexander epic by Ulrich von Eschenbach (see *ALEXANDER ROMANCES*). The Czech poem, of marked individuality, with its sustained descriptive passages, skilful handling of language and unobtrusive didacticism, is a minor masterpiece of courtly literature. Another striking epic, the Dalimil chronicle (c. 1330), portrays the history of the Czechs in a vivid, forthright style. Under the emperor Charles IV (1346-78) learning and literature flourished in Bohemia in both vernaculars, Czech and German. The emperor's own predilections were reflected in the place occupied in this literature by hagiography, both in the form of verse legends and of prose. The greatest achievement of this period is the verse *Legend of St. Catherine*.

In addition to hymns there are a few secular lyrics which may date from this period, where influences of courtly literature combine happily with popular elements. The existence of a vernacular drama is attested, among other things, by the *Mastičkář* ("The Quack"), a comic scene which no doubt originally formed part of an Easter play of traditional type. Of less intrinsic value are the verse adaptations of German poems on chivalrous themes (e.g., Tristan and Isolte, Duke Ernest).

From about 1350 prose genres began to be cultivated, first lives of saints, chronicles and the more anecdotal *exempla*, and then,

no doubt for the growing urban middle class, versions of several popular medieval tales (Alexander the Great, the Trojan War, etc.). From the last part of the century dates a group of verse, satires and didactical poems showing great originality and character, especially the anonymous satires of the Hradec manuscript and the political allegory *Nová rada* ("The New Council") written by Smil Flaška of Pardubice (c. 1349-1403) to defend the rights of the Bohemian nobility against the power of the crown.

**The 15th and 16th Centuries.**—A preoccupation with social and moral questions colours much Czech writing in the last part of the 14th century. Tomáš ze Štítného (of Štítný) (c. 1333-1405) wrote treatises on moral and theological questions in the vernacular and thus anticipated one of the main tendencies of the Hussite movement. This reform movement, inspired by John Huss (c. 1370-1415), dominated the life of Bohemia for the first half of the 15th century; amid the religious controversy and civil strife of this period it was natural for vernacular writing to be directed largely to practical and polemical purposes. Huss's own importance for Czech literature lies not only in his vernacular sermons and in the simple but flexible prose of his letters, but in the reform of the Czech orthography advocated in the treatise *De orthographia bohémica* (c. 1410). A direct product of the reform movement were the simple and moving hymns (notably *Ktož jsu božští bojovníci*, "You Who Are Warriors of God") composed by the Hussites. The events of the Hussite wars were reflected in the poems of the Bautzen manuscript (*Budyšínský rukopis*) and in a number of chronicles and other prose works.

Among the successors of Huss the most original was Petr Chelčický (c. 1390-c. 1460), who developed his radical social ideas and his pacifism in a series of striking treatises and homilies (notably *Síť viery pravé*, "The net of the true faith"). It was from Chelčický's ideas that the *Unitas fratrum* (or Bohemian Brethren) drew their inspiration: this sect was to be one of the most important sources of vernacular Czech literature in the next two centuries.

In the 16th century there was no revival of vernacular poetry, but there is a mass of prose literature in which didactic and scholarly writing predominates. The influence of humanism is apparent in the elegant style of the legal historian Viktorin Kornel of Všebrdy (c. 1460-1520). Of considerable interest are the small group of travel books from this period. A 15th-century translation of Marco Polo's *Million* inaugurated this genre; and in the 16th century there are both Czech and Latin works of the same kind. For more popular reading there were various collections of *novelle* and anecdotes, sometimes translated but also from native sources. The development of Czech prose in this period culminated in the translation of the Bible made by a group of scholars of the *Unitas fratrum* and known as the Bible of Kralice (published 1579-93). The language of this version came to be regarded as the model of classical Czech. The New Testament was based on the earlier translation by Jan Blahoslav (1523-71), the most prominent scholar of the time. Another remarkable scholar classified the riches of humanist Czech in his dictionaries—the historian Daniel Adam z Veleslavína (of Veleslavín) (1545-99).

**The 17th and 18th Centuries.**—The defeat of the Protestant Bohemian forces by the Habsburgs in the battle of the White Mountain (1620) brought the integration of the Czech provinces into the Habsburg empire and the eradication of Protestantism from the country. The old nobility was practically eliminated by execution or exile and replaced by newcomers with little or no knowledge of the Czech language. The literary traditions of the past two centuries, with their Protestant associations, were proscribed: it was only among the émigrés that they continued to find expression. Among these exiles Jan Amos Komenský (Comenius) (1592-1670) was pre-eminent. In addition to his Latin works on educational and theological problems his works in Czech reveal him as a writer and thinker of European stature. His *Labyrint světa a ráj srdce* ("Labyrinth of the World and Paradise of the Heart"), in particular, is one of the supreme achievements of Czech prose literature.

At home the Jesuits attempted to supply a new Catholic literature—hagiography, devotional prose, religious poetry and hymns;

some of this is of high quality, notably the poetry of Bedřich Bridel (1619–80). Among writers in Latin a special place is occupied by the Jesuit Bohuslav Balbín (1621–88), whose Czech patriotism expressed itself in studies of his country's past and in a remarkable "defense" of the Czech language.

By the beginning of the 18th century Czech had practically ceased to be used for higher literary purposes. Nevertheless, rough and ready vernacular dramas and chapbooks continued to be produced for the entertainment of the poorer townsfolk and the peasants. In the country too there arose a good deal of popular poetry, not only lyrical and narrative folk songs but rough and forceful expressions of peasant discontent.

**The National Revival.**—The historicism and antiquarianism of the 18th century led many Czech scholars to investigate the earlier literature and history of their country; a revival of Bohemian patriotism was, moreover, a natural reaction to the centralizing tendencies of the Habsburg government under Maria Theresa and was encouraged by the local nobility in the interests of their own power and prestige. Josef Dobrovský (q.v.; 1753–1829) had his roots in the world of *Aufklärung* ("Enlightenment") scholarship and became the arbiter and codifier of a revived Czech literary language. In the leisure which noble patronage enabled him to enjoy he devoted profound and penetrating study to the Czech language and literature of the middle ages and the Renaissance. In his grammar he provided a guide to correct language and a stimulus to good writing; and in his history of the older Czech literature he brought to light the neglected models which Czech writers might profitably follow. He himself wrote almost exclusively in Latin and German; but several of his contemporaries restored Czech to literary currency, notably Antonín Jaroslav Puchmajer (1769–1820) with his poetical Almanachs.

At the same time the social and political developments of the late 18th century created a public for Czech literature. The vernacular plays acted in Prague from 1786 and the beginnings of modern Czech journalism represented by the newspapers of Václav Matěj Kramerius (1753–1808) were directed at the new middle class of the growing Czech towns.

Dobrovský had contented himself with codifying the Czech language: Josef Jungmann (1773–1847) set out to extend and enrich its possibilities in order to render it capable of assuming the tasks of a modern literary language. This task he successfully accomplished through his translations (including that of Milton's *Paradise Lost*, 1811) and above all through his monumental Czech-German dictionary (1835–39). The revival of Czech national culture was also greatly furthered by two scholars: the Slovak philologist and archaeologist Pavel Josef Šafařík (q.v.; 1795–1861) and the Moravian historian František Palacký (q.v.; 1798–1876), whose history of Bohemia and Moravia is the last masterpiece of classical Czech.

Some Slovaks, particularly Protestants, were being drawn into the orbit of the Czech literary revival; foremost among them was Jan Kollár (q.v.; 1793–1852), whose allegorical sonnet cycle *Slávy Dcera* ("The Daughter of Slava"), despite its pedantry and excess of rhetoric, still has a certain fascination and is undoubtedly the first significant work of literature in the revived language.

A special position in this period belongs to the *Rukopis Královédvorský* ("Manuscript of Králové Dvůr") and *Rukopis Zelenohorský* ("Manuscript of Zelená Hora"), ostensibly Czech poems from the early middle ages but in fact forgeries executed by the brilliant and unscrupulous scholar and poet Václav Hanka (1791–1861) and others. Though their spurious character was finally proved toward the end of the century, largely by the efforts of Jan Gebauer and Tomáš G. Masaryk, they can still hold their own as examples of romantic poetry, with echoes of the popular poetry of the southern Slavs. The direct influence of popular poetry can also be discerned in the ballads of František Ladislav Čelakovský (1799–1852) and more subtly in those of Karel Jaromír Erben (1811–70). The plays of Josef Kajetán Tyl (1808–56) and Václav Kliment Klicpera (1792–1859) were considerably important in establishing a Czech theatrical tradition but have little lasting value.

The greatest poet of Czech romanticism, perhaps still the greatest of all Czech poets, was Karel Hynek Mácha (q.v.; 1810–36).

His lyrics, prose fragments and above all the lyrical epic *Máj* show his indebtedness in externals to Byron, Walter Scott and the Polish romantics; but the derivative character of the material is transcended by the intensity of the poetic vision and the perfection of the language in which it is expressed.

In the 1840s a reaction from the attitudes and literary forms of romanticism became evident in the work of a number of authors, most notably in that of Karel Havlíček-Borovský (1821–56) and Božena Němcová (née Barbora Panklová; 1820–82). Both were concerned with practical issues rather than with romantic visions of Czech past and future greatness; and both were masters of prose style who did much to emancipate Czech prose from the older classical manner and bring it nearer to the language of every day. Havlíček was a political journalist whose achievement lies not only in the numerous critical articles and sketches in which he fought for Czech rights against Habsburg absolutism, but also in his brilliant satirical poems, notably those written in exile at Brixen just before his death (*Král Lávra*—"King Lavra"; *Tyrolské elegie*—"Tyrolean Elegies"; and *Křest svatého Vladimíra*—"The Baptism of St. Vladimir"). Božena Němcová, the first woman to make a significant contribution to Czech literature, is best known for *Babička* ("The Grandmother"), a portrayal of Czech country life in a series of sketches held together by the central figure. Although the conception of peasant existence is an idealized one the descriptions are precise and realistic; and the language has a firmness and individuality which, while drawing from the speech of the common people, nevertheless betrays an artistry which was new in Czech prose. *Babička* was the most successful of the many sketches and stories of country life which form the main body of Němcová's work.

**1848–1918.**—The work of Havlíček, Erben and Němcová, all at the peak of their achievement in the 1850s, forms a bridge from the first, romantic phase of the revived Czech literature to the second half of the century in which a more numerous body of authors, writing for an expanding public, try to establish a literature of less parochial character which might occupy a worthy place in its own right among the other literatures of Europe. In 1858 the almanach *Máj* appeared, dedicated to the memory of Mácha and containing the work of a number of young authors among whom Jan Neruda (1834–91) and Vítězslav Hálek (1835–74) were pre-eminent. In Mácha these authors saw the literary revolutionary whose independence of authority and tradition they proposed to follow. They also owed much to the ideas of Havlíček. Their aim was to create a new Czech literature which should reflect the liberalism and practical nationalism with which they were imbued. Neruda was the most successful author of this group. He was a prolific writer who is now chiefly remembered for his lyrics and his prose. His lyrics, ranging from a melancholy romantic vein to one of patriotic enthusiasm, are often rhetorical; but the best of them (notably *Zpěvy páteční*—"Good Friday Songs"), as well as his lively ballads, are of high merit. Of more interest to the modern reader are his prose sketches, particularly *Povídky malostranské* ("Tales of the Little Quarter"), in which the life of Prague is portrayed with a humour and humanity which has affinities with the "poetic realism" of Gottfried Keller. The work of Neruda's friend Hálek, though highly popular in its day, has proved less lasting: his best achievement was in his lyrics (in particular *Večerní písně*—"Evening Songs").

The most significant novelist of the *Máj* group was Karolína Světlá (pseudonym of Johanna Mužáková; 1830–99). Her novels of early 19th-century Prague society and of the north Bohemian countryside contain romantic elements of theme and plot but show considerable skill in psychological analysis. Moral and social problems, and in particular the position of women in 19th-century society, are among the dominant themes of her work.

It was under the auspices of the *Máj* group that Adolf Heyduk (1835–1923) began his literary career. Of his vast output (lyrics, ballads, epics) his patriotic poetry has best stood the test of time, notably the poems in which he was inspired by the kinship between Czechs and Slovaks. Of all the poets of the *Máj* group the one who was closest in mood to Mácha (though remaining far behind him in achievement) was Rudolf Mayer (1837–65).

By the 1870s Czech literature had fully established itself in poetry and the novel. In the drama progress was slower; even the establishment of a national theatre in 1883 did not cause native talent to spring forward in this field as it had in others. Literary life in the 1870s and 1880s crystallized in the main round two groups or tendencies associated with the periodicals *Lumír* and *Ruch* ("Stir"). The former stressed the necessity to Europeanize Czech literature and looked to the literatures of France, Italy and England for inspiration. The latter looked rather to the strength of native traditions and themes, and to those of kindred Slavonic peoples. The difference was one of emphasis rather than a hard and fast division; but it is reflected in the work of some of the main writers of the period.

The leading representative of the cosmopolitan tendency was Jaroslav Vrchlický (pseudonym of Emil Frida; 1853–1912), probably the most prolific of all Czech writers: the rise and fall of his reputation as well as the character of his work recall Tennyson and Victor Hugo. His lyrics, though marred by rhetoric and an excessive metrical virtuosity, nevertheless show an amazing mastery of language. His vast cycle of historical epics (consciously inspired by Hugo and Leconte de Lisle) contains his best work: it has grandeur of conception, felicity of language and a sense both of the complexity of the human personality and of the drama of history. Perhaps his greatest influence on Czech literature was exercised, however, by his numerous (and often admirable) translations (Shakespeare's sonnets, works of Shelley, Byron, Tennyson, Walt Whitman, Goethe, Corneille, Molière, Hugo, Leconte de Lisle, Baudelaire, Dante, Petrarch, Leopardi, Calderón, Camões and much else besides). It is easy to point out the defects in Vrchlický's work, but his importance in the fashioning of the modern Czech poetical language must not be underestimated.

The cosmopolitan trend in the literature of the 1880s also found memorable expression in the poetry and novels of Julius Zeyer (1841–1901). The formal skill of his neoromantic lyrics and epics is considerable. More original are his novels and stories, particularly the semi-autobiographical *Jan Maria Plojhar*. The lyrical poetry of Josef Václav Sládek (1845–1912) shows affinities with Vrchlický and Zeyer; but in many of his themes he shows greater affinity with the "national" group. He is best remembered for his excellent translation of most of Shakespeare's plays.

The principal figure of the *Ruch* group was Svatopluk Čech (1846–1908). His work is inspired by love of his nation and its traditions and by a passionate liberal humanism. In a number of epics he portrayed the Hussite period (e.g., *Adamité, Václav z Michalovic*); and one of his most popular works *Ve stínu lípy* ("In the Shade of the Lime-Tree") gives an idyllic picture of Czech country life. In *Písň otroka* ("Songs of a Slave") the hardships of negro slaves under a ruthless taskmaster were meant to symbolize the position of the Czechs under the Habsburgs. In his prose satires he created the original figure of "Mr. Brouček" who satirized the philistinism of the Czech middle classes.

In the Czech novel of the last quarter of the century a marked trend toward realism of description is the common factor. This is even apparent in the two major historical novelists, Alois Jirásek (q.v.; 1851–1930) and Zikmund Winter (1846–1912). Though both of them present a romanticized version of the national history of the Czechs, yet the details of their reconstruction of past scenes and events is based on scholarly research, in sympathy with the efforts of contemporary historians. The novels of Jirásek present the entire history of the Czechs up to his own time, concentrating in particular on the two periods which seemed to him of vital significance: the Hussite period, to which he devoted a vast trilogy, and the national revival of 1780 onward, which is the subject of the five-volume novel *F. L. Věk*. His mature craftsmanship is seen at its best in his novel of the period of national decline *Temno* ("Darkness"). Winter's novels were a by-product of his work as a historian; his *Mistr Kampanus* is a fine portrayal of Bohemia at the time of the battle of the White Mountain (1620).

Many novelists now devoted themselves to the description of contemporary life. Realistic pictures of the Czech countryside were painted in the novels of Jan Herben (1857–1936), Karel

Václav Rais (1859–1926) and Teréza Nováková (1853–1912). City life and the problems of industrialization had already been treated by Jakub Arbes (1840–1914). They loom large in *Santa Lucia*, the haunting novel of Prague by Vilém Mrštík (1863–1912).

In the last decade of the century new trends in poetry began to show themselves. Lyrics of more subtle content and more complex form (including free rhythms) were written by Antonín Sova (1864–1928). About the turn of the century there appeared the best work of two of the most remarkable of Czech poets: Otakar Březina (q.v.; pseudonym of Václav Jebavý; 1868–1929) and Petr Bezruč (q.v.; pseudonym of Vladimír Vašek; 1867–1958). Březina expressed his personal religion in a language of great subtlety and originality; his metrical structures (including free rhythms) had great influence on later poets. Bezruč was a regional poet, obsessed by the national and social oppression of the Czechs of Silesia. This theme, sometimes interwoven with autobiographical elements, he developed in poems of elemental force and sincerity. A violent reaction to the restraints of bourgeois civilization expressed itself in the ecstatic sensualism of Stanislav Kostka Neumann (1875–1947) and Fráňa Srámek (1877–1952).

In the 1890s another form of critical reaction to the romantic idealism of the national revival had already inspired the historical and sociological writings of T. G. Masaryk (q.v.; 1850–1937), whose importance in Czech life lies mainly outside the field of literature. A new and more mature approach to literary criticism showed itself only a little later in the work of František Xaver Šalda (1867–1937) whose sensitive interpretations of his country's greatest writers have not been surpassed.

**After 1918.**—With the establishment of an independent Czechoslovak state in 1918, new possibilities opened for Czech writers, and there was great, even feverish, literary activity. Some of the best achievements of Czech literature date from this period, especially in lyrical poetry.

In the period beginning in 1918, Czech lyrical poetry was of the utmost variety, and some of it of the highest quality. Among the great figures of modern Czech literature are Josef Hora (1891–1945), František Halas (1901–49), Vítězslav Nezval (1900–58) and Jaroslav Seifert (1901– ). Of these Hora possessed perhaps the profoundest lyrical vein; the talent of Nezval was the most far-ranging but also the most uncontrolled. Lyrical talent of a high order is also apparent in the poems of Vladimír Holan (1905– ) and František Hrubín (1910– ).

It was after World War I, also, that the Czech drama came into its own, notably in the idealistic and satirical plays of Karel Čapek (q.v., 1890–1938) and in the versatile talent of František Langer (1888–1965).

The realistic novel of Prague life had been successfully cultivated by Karel Matěj Čapek-Chod (1860–1927) and in lighter vein by Ignát Herrmann (1854–1935). It was not from this direction, however, that the principal postwar achievements were to come. Czech narrative prose reached its peak in the work of three equally versatile but very different writers: Karel Čapek, Ivan Olbracht (pseudonym of Kamil Zeman; 1882–1952) and Vladislav Vančura (1891–1942). Čapek wrote Wellsian fantasies, subtle psychological studies and stories of Prague life. His style at its best derives force and colour from the introduction of elements of popular speech. Olbracht's most successful works have a Ruthenian background. In contradistinction to Čapek and Olbracht Vančura cultivated a complex, mannered style, often with great success. Among several novelists preoccupied by the personal and social problems of the interwar period the most noteworthy were Marie Majerová (1882–1958) and Marie Pujmanová (1893–1958).

From the mass of fiction dealing with World War II and the establishment of the Communist government, the novels of Jan Otčenášek (1924– ) stand out as the most effective.

#### SLOVAK LITERATURE

Until the 18th century there was no systematic attempt to establish a literary language from the Slovak dialects which, though closely related to Czech, developed an identity from the early middle ages. The work of SS. Cyril and Methodius (q.v.) and their

liturgical language may have influenced western Slovakia, but after Slovakia was conquered by the Magyars in the early 9th century (followed by incorporation into territories under Hungarian rule in the 11th) there are no traces of a written Slavonic language for several centuries. Clearly in the later middle ages Czech (often with an admixture of Slovak elements) was fairly widely used for legal and administrative purposes: the first substantial Czech text from Slovakia is the Book of Žilina, a translation made in 1473 of a German legal text. Other examples of Czech texts with Slovak colouring (e.g., folksongs) have been preserved from the early modern period. Not until the middle of the 18th century, however, was any systematic attempt made to establish a Slovak literary language. The decline of literary Czech in the early 18th century caused an increase of local colouring in the devotional texts produced by both Catholics and Calvinists. With Anton Bernolák (1762–1813) these tendencies were consolidated. In a grammar (1790) and a dictionary (6 vol., 1825–27), Bernolák codified a literary language based mainly on western Slovak cultivated usage. In an era of reviving national consciousness this language was taken up by a number of writers. Preeminent was Ján Hollý (1785–1849), who wrote lyrics, idylls and national epics. Among prose writers the most noteworthy follower was Juro Fándlí (1750–1811), author of a series of religious and practical treatises. Of far greater literary value, however, was the didactic novel *René* (1783–85), written in a strongly Slovakized Czech by Jozef Ignác Bajza (1755–1836).

Bernolák's language was not accepted by the Protestants of Slovakia, who used Czech as their liturgical language and for the most part accepted with enthusiasm the revived literary Czech codified by Dobrovský and Jungmann (see above). By the 1840s, however, Slovak national feeling among the Catholic majority was so strong that there was little possibility of their accepting Czech as their written language. The narrowly based western Slovak of Bernolák was inadequate; and when in the 1840s the brilliant linguist and ardent patriot L'udovít Štúr (1815–56) codified a new form of literary Slovak based on the central dialects the way was clear for its acceptance. (See also SLOVAKIA; SLOVAK LANGUAGE.)

The new language was immediately taken up by a group of talented poets. Andrej Sládkovič (pseudonym of Ondrej Braza-toris; 1820–72) produced in *Marína* (1846) a national epic which, though owing a debt to Pushkin's *Onegin* (1833) and less so to Jan Kollár, had individuality and freshness. Samo Chalupka (1812–83) composed lyrics reflecting the language of Slovak folksongs. The most significant figure was the romantic Janko Král' (1822–76), whose exploits in the revolution and war of 1848–49 made him a legend in the memory of his countrymen. His ballads, epics and lyrics are among the most original products of Slavonic romanticism. The dual influence of Slovak folksongs and romantic poetry (especially Mácha's *Máj*; see above, *Czech Literature*) also appear in the work of Ján Botto (1829–81), notably in his epic *Smrt' Jánošíkova* (1862, "Jánošík's Death").

The first Slovak dramatist of note was Ján Chalupka (1791–1871), whose works, among them the lively satire *Kocourkovo* (1830), were written in Czech. Ján Palárik (1822–70) used the new literary language: his comedies, produced in the 1850s and '60s, portray Slovak society with irony but also with sympathy. The novel was the last genre to be established in Czech. Before World War I the only notable novelist was Martin Kukučín (pseudonym of Matej Bencúr; 1860–1928), a writer of unusual talent whose best work deals with life on the Dalmatian coast.

The chief strength of Slovak literature continued to be in the lyric; and the preeminent prewar poet was Hviezdoslav (Pavol Országh, q.v.; 1849–1921). His output was vast and at his best he was a lyric poet of a high order. He enriched the Slovak poetic language by his original work and by translations, especially from English, Russian, German and Hungarian. Other notable poets were the Russophile Svetozár Hurban Vajanský (1847–1916), and Ivan Krasko (pseudonym of Ján Botto; 1876–1958) whose two volumes of verse, *Nox et solitudo* (1909) and *Verše* (1912), are among the finest achievements of Slovak literature.

After World War I Slovak literature came of age. While following the general tendencies of European literature, Slovak writ-

ers retained an individual flavour. Their greatest successes were in lyrical poetry, with such writers as Martin Rázus (1888–1937), Janko Jesenský (1873–1945), Emil Boleslav Lukáč (1900– ), Ján Smrek (pseudonym of Ján Čietek; 1898– ), Ján Poničan (1902– ) and Ladislav Novomeský (1904– ). In the novel the country tales of Timrava (pseudonym of Božena Slančíková; 1867–1951), the vast chronicle of 20th-century Slovakia by Milo Urban (1904– ) and the lyrical prose of Margita Figuli (1909– ) are particularly outstanding.

The problems of World War II and its aftermath of Communist government found vivid and personal expression in the work of Ladislav Mňačko (1919– ) and Alfonz Bednár (1914– ).

Němcová, "World's Classics" (1967). (R. Ax.)

**CZECHOSLOVAK ORTHODOX CHURCH**, the national autocephalous representative in Czechoslovakia of the Orthodox Eastern Church (q.v.). It follows the traditions established by SS. Cyril and Methodius, who in the 9th century brought Christianity to the Czech lands. Though this territory was later lost to the Roman Church the Orthodox position was better in eastern Slovakia until 1649, when many believers were lost to the Uniats. In the 19th century some Czechs formed an Orthodox Church, and by 1910 about 1,000 persons were following the Orthodox faith. After World War I an Orthodox Church was formed in Bohemia and Moravia by Bishop Gorazd, who was consecrated as the first independent bishop in 1921. In World War II, the bishop together with four other members of the Orthodox clergy was executed by the Nazis after members of the resistance movement who had killed Reinhard Heydrich were found hiding in an Orthodox church. All the work of the church was forcibly discontinued and the church disbanded. It continued its work only in the eparchy of Mukachevo in eastern Slovakia.

After the war the church was revived and, having no bishop, a general assembly of laymen and clergy asked to come under the jurisdiction of the Russian Orthodox Church. At the same time about 10,000 Czechs of Orthodox faith returned to Czechoslovakia after having emigrated under the Austrian monarchy to Volhynia. At the 1950 Presev conference the laymen and clergy of the Uniats decided to return to the Orthodox Church. This growth in numbers made possible the establishment of four indigenous bishoprics: Prague, Olomouc, Presov and Michalovce, upon which the Russian Orthodox Church immediately acknowledged the autocephalous status of the Czechoslovak Orthodox Church. The head of the church is the metropolitan of Prague and Czechoslovakia. There is a theological faculty at Presov, and the church brings out three monthly publications in Czech, Slovak and Ukrainian.

**CZERNY, KARL** (1791–1857), Austrian pianist, teacher and composer known for his pedagogical works for the piano, was born in Vienna on Feb. 20, 1791, and studied the piano first with his father, Wenzel Czerny, and later with Beethoven. He was a teacher in Vienna at the age of 15, his pupils including Beethoven's nephew and Liszt. His published works of all kinds number nearly 1,000. He made ingenious arrangements of orchestral works including versions for eight pianos, four hands at each, of two overtures of Rossini. He is known, however, by his studies, greatly esteemed by later teachers, which include the *School of Velocity*, the *School of Virtuosity* and the *School of the Left Hand*. Czerny died in Vienna on July 15, 1857.

**BIBLIOGRAPHY.**—H. Steger, *Beiträge zu Czernys Leben und Schaffen* (1924); F. Hasenöhr, *Czernys solistische Klavierwerke* (1927); A. Dreetz, *Czerny und Beethoven* (1932).

**D** THIS letter has retained the fourth place in the alphabet from the earliest point at which it appears in history. It corresponds to Semitic **ד** (daleth) and Greek **Δ** (delta). The form is thought to derive from an early pictograph, possibly Egyptian, indicating the folding door of a tent. The rounded form **D** occurs in the Chalcidic alphabet, whence the Latin alphabet may have acquired it by way of the Etruscans. The letter has retained the rounded form that it had in the Latin alphabet until the present day.

Latin cursive forms were **ɔ** (5th century) and **ɔ** (6th century). In these the right-hand rounded line of the majuscule letter is carried far above the level of its junction with the stroke. From these forms and from the uncial arose the Carolingian and our own minuscule **d**.

The sound consistently represented by the letter in Semitic, Greek, Latin and the modern languages of Europe is the voiced

**t** when the **P** originally resulting from the **t** has been subsequently altered by the change familiarly known as "Verner's Law," the occurrence of which depended on the place of the Indo-European accent (so, for example, the prior **d** in *hundred*, Sanskrit *śatám*, Greek *ἑκατόν*, Latin *centum*). (See also GERMANIC LANGUAGES.)

In music, **D** is the fourth note of the musical alphabet and the second note of the scale of **C**. In former times it gave its name also to one of two or three clefs which are now no longer in use. (See MUSICAL NOTATION.) Used as an abbreviation, **D** has several meanings, e.g., *m.d.* = *main droite*; *d.c.* = *da capo*; *d.s.* = *dal segno*.

In chemistry, the letter **D** is used as the symbol for deuterium. The British penny is signified by *d*, from the Latin *denarius*, the name of a Roman silver coin. The Roman numeral **D** stands for "500" or one-half of the uncial form of **M**, "1,000." (J. W. P.)

**DAB**, a common name applied to several species of flounder belonging to the families Bothidae and Pleuronectidae, especially to *Limanda* and *Citharichthys* species. The North American dabs include the speckled sand dab (*C. stigmaeus*) and the longhead dab (*L. proboscidea*), both of the Pacific coast. The European dab (*L. limanda*) is typical: it is brown or ashen gray with irregular dark markings and close-set scales, and attains a length of 12 in. See also FLATFISH.

**DABCHICK**, the popular name of the little grebe (*Podiceps ruficollis*), a diving bird, the smallest European member of the family Podicipedidae. The dabchick frequents ponds and rivers throughout most of the old world, exclusive of the arctic regions. It feeds on crustaceans, mollusks and insects and some vegetable matter. The bulky nest, composed of wet, decaying aquatic plants, may rest in shallow water or may float. The name dabchick is also applied to small

ERIC HOSKING  
EUROPEAN DABCHICK OR LITTLE GREBE (PODICEPS RUFICOLLIS) WITH NESTLINGS

American grebes, especially the piedbilled (*Podilymbus podiceps*). See GREBE. (E. R. BE.)

**DABROWA GORNICZA**, a town in the *województwo* of Katowice, Poland, part of the urban group of the Upper Silesian industrial region, lies on the eastern edge of the Silesian uplands, on the Czarna Przemsza river (a tributary of the Vistula), 9 mi. E.N.E. of Katowice city. Pop. (1960) 42,000. Dabrowa Gornicza is an old mining and iron-foundry centre where exploitation of one of the thickest coal-seams in the world (up to 24 m. [78.7 ft.]), known as the "Reden" seam, was started in 1796. Part of the coal-seam is now a national preserve. The town is on the Katowice-Warsaw railway line. Dabrowa Gornicza flourished during the Congress kingdom (19th century), when it was a centre for Polish scientific research in mining and metallurgy.

(K. M. WL.)

**DACCA**, the capital of East Pakistan and second seat of the Pakistan government, also gives its name to a district and division of the province. The city is situated on the left bank of the Burhi Ganga, a tributary of the Dhaleswari which flows from the Jamuna

dental stop. In English this sound, as well as the unvoiced sound represented by *t*, has become alveolar, that is to say, is pronounced by the pressure of the tongue upon the gums rather than upon the teeth.

The etymological value of *d* in words of native English origin is generally the same as that of German *t* (*th*), Sanskrit *dh*, Greek *θ*, Latin *f* (initial) or *d* or *b* (medial), all being derived from *dh* in the parent Indo-European speech (e.g., English *do*, German *thun*, Sanskrit *dadhāmi*, Greek *τίθημι*, Latin *facio* but *condo*). In some other instances *d* is derived from Indo-European

(the main stream of the Brahmaputra) into the Meghna river. It is 10 mi. from Narayanganj, a great river port which links it by steamer with many other centres. Pop. (1961) 556,712.

Much of Dacca's great past is preserved in rich monuments of impressive beauty such as the Lal Bagh fort which was begun by Azam Shah, the third son of the emperor Aurangzeb, in 1678 but was never completed. Architecturally the most interesting building in the fort is the tomb of Bibi Peri (daughter of Shaista Khan and great-niece of Nur Jahan), who died in 1684. It is built entirely of black basalt, gray sandstone and white marble with intricate design and workmanship. Other buildings of the Mogul period are the Bara Katra great caravansary (built by Mir Abdul Qasim in 1664), the Chhota Katra small caravansary (built by Shaista Khan in 1663) and Husaini Dalan, a religious monument of the Shi'ah sect (built by Mir Murad in 1642). There are not less than 700 mosques dating from as far back as 1456, several Hindu temples, the most notable of which is Dhakeswari (17th century), pagodas of Burmese origin, monasteries of Siamese workmanship and several churches. Tejgaon church (1677) was built by the Portuguese mission. The principal modern buildings include those of the high court (1911), Dacca university and other colleges, the museum, government secretariat, public library, Shah Bagh hotel, New market, Dacca club and the stadium. Many of these are grouped round a large park, the Ramna, one mile from the city centre. New residential accommodation includes the Azimpur colony. Nawabpur road is the main shopping centre inside the city and its extension, Jinnah avenue, leading to the Ramna area, is the chief commercial quarter. The city is noted for its cottage industries. Dacca was once world famous for its extremely fine muslins and good muslin known as *jamdani* continues to be woven there with machine yarn. Dacca embroidery is unique: *chikan* and *kasidas* (muslin embroidered with silk) are two of the chief products. The city is also the centre of the manufacture of cotton saris and jute carpets. Other industries include the making of silk, conch-shell bangles and bracelets, mother-of-pearl bangles and horn combs, gold and silver (especially silver filigree) work and boatbuilding. The greatest industrial area of East Pakistan extends from Dacca to Narayanganj, with jute and cotton textile, hosiery and oil mills and match, shoe and soap factories and glass-works. The light industrial area of Tejgaon has rubber, oil and engineering industries. By rail Dacca is connected with Chittagong in the south and Bahadurabad on the Jamuna in the north. Dacca airport (3 mi. away at Tejgaon) is used by international airlines.

The origin of the name Dacca (Dhaka) is uncertain. Alternative derivations are: from the dhak (*Butea frondosa*), a tree said to have once been common there, or from Dhakeswari ("the hidden goddess"), whose shrine is in the western part of the city. Odd finds of coins and antiquities take its history back to the end of the 1st millennium A.D. In the 15th century Dacca was ruled by a line of Muslim sultans. From 1608 to 1639 the city was the capital of the province of Bengal, but in the latter year the government was transferred to the Rajmahal hills, where it remained for 21 years. In 1660 Mir Jumla, viceroy of Aurangzeb, again made Dacca the capital and it remained so until 1704, when the court was moved to Murshidabad. Dacca was a great centre of trade, mostly conducted by sea. In the 17th–18th centuries there were English, Dutch and French factories there. The population of the city at that time is variously estimated at 900,000 to 1,000,000. With the shift of the capital to Murshidabad and the decay of the muslin industry in the 18th century, it began to decline in size and population. In 1765 it passed under British rule. In 1824 Bishop Reginald Heber estimated its population at 300,000 but by the first census in 1872 it had decreased to 69,212. Subsequently the population steadily increased, stimulated from 1905 by its status for seven years as capital of the newly created province of Eastern Bengal and Assam during the first partition of Bengal. Dacca college (1842) formed the nucleus of Dacca university, established finally in 1921. Even after the annulment of the first partition in April 1912, Dacca retained its importance as a seat of learning and as a commercial centre, lying in the heart of the richest agricultural part of undivided Bengal. After the

establishment of Pakistan, Dacca became the capital of East Bengal and later of East Pakistan. While most of the Hindu population fled to India there was a large influx of Muslim refugees, mainly from West Bengal.

DACCA DISTRICT has an area of 2,882 sq.mi. and a population (1961) of 5,095,745. The district consists of a level plain bounded on three sides by the Meghna, the Ganges (or Padma) and the Jamuna, and watered by a network of rivers and streams such as the Dhaleswari, the Burhi Ganga and the Lakhya. About 20 mi. N. of Dacca city small ridges not more than 50–60 ft. high occur in the Madhupur jungle, stretching into Mymensingh district. Rice is the principal crop, followed by jute. The industries consist of jute pressing, rope-, string- and basketmaking, the weaving of cotton fabrics and boatbuilding. At Vikrampur (15 mi. from Dacca city) is an ancient city site, formerly the capital of the Pala rulers of Bengal (8th–13th centuries).

DACCA DIVISION lies in the central part of the province of East Pakistan, flanked by Chittagong division on the east and Rajshahi and Khulna divisions on the northwest and southwest. Pop. (1961) 15,293,596. Area 11,937 sq.mi. It consists of the three districts of Dacca, Mymensingh (*q.v.*) and Faridpur (*q.v.*).

See S. M. Taifoor, *Glimpses of old Dhaka* (1952); A. H. Dani, *Dacca, a Record of Its Changing Fortunes* (1956). (K. S. Ad.)

DACE, a common name applied to any of several edible freshwater fishes of the carp family, Cyprinidae, closely related to the European chub (*q.v.*) but having a smaller head and smaller mouth. The North American daces include the redbellies (*Chrosomus*); the redside and rosieside daces (*Clinostomus*); the creek chub or horned dace (*Semotilus atromaculatus*); and the black-nose, speckled and longnose daces (*Rhinichthys*). The European dace (dare or dart) is *Leuciscus leuciscus*, found in the rivers of Siberia, of Europe north of the Alps and Pyrenees, and of England. All daces are slender, active fishes, generally silvery; they rarely exceed 12 in.

DACH, SIMON (1605–1659), German poet, is noted for the sweetness and simplicity of his lyrics. Dach was born at Memel, in East Prussia, on July 29, 1605. He was professor of poetry at the University of Königsberg from 1639 and became a leader of the Königsberg group of poets which played a significant part in the early baroque movement. (see GERMAN LITERATURE). Dach died at Königsberg on April 15, 1659.

His best-known lyric, frequently found in anthologies, is "Der Mensch hat nichts so eigen." "Ännchen von Tharau" is no longer attributed to him. In addition to secular lyrics Dach wrote excellent hymns. His works have been edited by W. Ziesemer, in four volumes (1936–38).

DACHAU, a town of Germany, which after partition of the nation following World War II was in the Land of Bavaria, Federal Republic of Germany. It lies 17 km. (11 mi.) N.W. of Munich by road. Pop. (1961) 29,068. Dachau is on a hill on whose summit are the castle of the Wittelsbacher and a parish church (1625). Industries include the production of paper, cardboard and electrical equipment. First mentioned in 805, Dachau remained a small market town until the 20th century. It was given civic status in 1934.

In March 1933, on the site of an ammunition factory erected in 1917, a concentration camp, infamous for the brutalities practised in it, was opened within the boundaries of Dachau. It was set up and run by the Nazi S.S. (*Schutzstaffel*). About 70,000 out of 206,202 detainees lost their lives in the gas chamber or in other ways. The camp later housed refugees, but the crematorium area was preserved as a shrine and a warning. A monument to the dead was unveiled in 1960.

DACIA, the ancient Roman name given primarily to the area in modern Rumania of the Carpathian mountains and Transylvania, though the Dacian people had earlier also occupied lands south of the Danube river and north of the mountains, and the Roman province eventually included wider territories both to the north and east. The Dacians were a westerly branch of the Getae (*q.v.*) and first appear in the Athenian slave market in the 4th century B.C., after which *Daos* (Lat. *Davus*) is common as a slave name in comedy. Though speaking a Thracian dialect the Dacians

had absorbed considerable Scythian influence, of which the most important indication was their cult of the Scythian deity Zalmoxis (plausibly identified with the bearskin) and their belief in immortality. They were sedentary grain growers; they traded with Greece from early Hellenistic times; they used Greek coins; and they worked their rich mines of silver, iron and above all gold.

Dacians appear in alliance with other tribes against Roman generals in 112, 109 and 75 B.C., but the unified kingdom erected about 60–50 B.C. by the Dacian king Burebista was much more formidable. His power extended to the Black sea (where the Greek cities of south Russia were overwhelmed), west beyond the Tisa (Tisza) river, north to modern Slovakia (see BORI), and south of the Danube to Thrace and to the area beyond Belgrade. Burebista seems to have offered Pompey assistance in 49, and in 44 Caesar was planning a vast expedition against the new kingdom; but Caesar was murdered, and soon afterward Burebista also. His kingdom broke up into at least four parts, but the Dacians continued to harass Rome, an invasion in 11 or 10 B.C. being particularly devastating. Augustan generals gradually pushed them back from the left bank of the Danube, while also settling 80,000 men within the Roman province of Moesia on the right bank, and no further trouble is recorded until autumn A.D. 69 when the Dacians found Moesia denuded by the departure of the legions to fight Vitellius (q.v.). After capturing a number of forts they were beaten back by Vespasian's general Gaius Licinius Mucianus, then on his way to Italy.

The origins of the more serious wars under the emperors Domitian and Trajan are hard to discern (see DECEBALUS). Roman provocation is not ruled out, but the first event was a Dacian raid in A.D. 85, the Moesian governor Oppius Sabinus being killed. Domitian restored the situation next year, but his commander Cornelius Fuscus was then killed with a large part of his army in an attempted invasion. In 88 Rome won a victory at Tapae near the Iron Gate pass, but owing to difficulties with tribes farther west (see MARCOMANNI) Domitian gave Dacia a favourable peace; Roman suzerainty was recognized, but the Dacians received a subsidy and the loan of engineers.

In 101 Trajan (his pretext is not recorded) reopened the struggle and at the end of two years dictated a peace under which the Dacian capital, Sarmizegethusa (probably near modern Sarmizegetusa, Rumania), received a Roman garrison. In 105 the war was renewed, and in 106 the whole country was subdued, large parts of its population being exterminated or driven northward. Trajan acquired enormous booty, and the mines, perhaps a motive for the conquest, were immediately exploited; important roads were built; and Sarmizegethusa and Tsierna (mod. Orșova) became colonies. The new Roman province was at first put under a consular legate with at least two legions, but under Hadrian it was divided: Dacia Superior under a praetorian legate comprised Transylvania, with a single legion at Apulum (Alba Iulia, Ger. Karlsburg), while Dacia Inferior in what was afterward Walachia was governed by a procurator. In 159 Antoninus Pius redivided the area into three provinces, the *Tres Daciae* (Dacia Porolissensis, Dacia Apulensis and Dacia Malvensis), all subordinate to one governor of consular rank; Marcus Aurelius made them a single military area about 168.

The limits of Roman territory were probably never clearly defined, but militarily the occupation had great advantages for Rome. It was not so much the unsatisfactory character of the Dacian frontiers as the need for troops south of the Danube that caused the abandonment of the province by Aurelian about 270. For the later history of the area see RUMANIA; VLACHS.

Both Dacian warriors and Dacian peasants are portrayed realistically on Trajan's column in Rome. The sculptor also depicts the strength of their mountain fortresses, some of which have been excavated. By Domitian's time the Dacians enjoyed a compact government and a fairly advanced culture, though they retained the division into the upper class of *pileati* (wearing the felt hat) and the proletariat of *capillati* (who wore their hair long). But the people who entered after the conquest were able to impose new cults and customs from all parts of the Roman empire, and the influence of the Latin language on modern Rumanian remains

the most striking survival in this region from ancient times (see RUMANIAN LANGUAGE).

**BIBLIOGRAPHY.**—C. G. Brandis in Pauly-Wissowa, *Real-Encyclopädie der Altertumswissenschaft*, 1948–1976 (1901), and Supplement, vol. i, 261–264 (1903); V. Parvan, *Dacia* (1928); V. G. Childe, *The Danube in Prehistory* (1929); C. Patsch, "Beiträge zur Völkerkunde von Südosteuropa V," *Wiener Sitzungsberichte*, 214, i (1932) and 217, i (1937); R. Syme, "Lentulus and the Origin of Moesia," *Journal of Roman Studies*, 24:113–137 (1934); A. Alföldi, R. Syme and R. P. Longden in *Cambridge Ancient History*, vol. xi, ch. 2, 4 and 6 (1936, reprinted 1954). (G. E. F. C.)

**DACIER, ANDRÉ** (1651–1722), French classical scholar who, with his wife (see below), was responsible for some of the famous Delphin series of editions of Latin classics. Born at Castres, Languedoc, in 1651, he studied at Saumur with the humanist Tannegui Lefebvre (1615–1672), whose daughter, Anne, he married in 1683.

Dacier was made keeper of the library of the Louvre and in 1695 was elected to the Académie Française, of which he became permanent secretary in 1713. He died in Paris, Sept. 18, 1722. His pedantic, somewhat uninspired, works include editions of Horace, Aristotle's *Poetics*, two plays by Sophocles, some Epicte-tus and Hippocrates, Plutarch's *Lives*, and, for the Delphin series, of Festus and Flaccus.

His wife, ANNE LEFEBVRE, was born in Preuilly-sur-Claise in 1654 and educated by her father. Her work as classical commentator, translator and editor, begun before her marriage, attained greater fame than that of her husband. Her most celebrated work, her prose translations of the *Iliad* (1699) and the *Odyssey* (1708), rapidly became known throughout Europe, and by making Homer widely read among French men of letters, played an important part in the famous controversy about the merits of ancient and modern authors, in which she herself became keenly involved. Mme Dacier's own enthusiastic admiration of Homer and scholarly study of the texts override her occasional inadequacies as stylist and translator. Her other works include Delphin editions of Florus, Dictys Cretensis, Aurelius Victor and Eutropius; an edition of Callimachus; and translations of Anacreon, Sappho, Terence and plays by Plautus and Aristophanes, and, with her husband, of Horace. She died in Paris, Aug. 7, 1720.

**BIBLIOGRAPHY.**—R. Rigault, *Histoire de la querelle des anciens et des modernes* (1856); J. E. Sandys, *History of Classical Scholarship*, vol. 2 (1908); E. Erger, *L'Hellenisme en France*, vol. 2 (1869).

**DACITE**, in petrology, a volcanic rock which may be considered a quartz-bearing variety of andesite (q.v.). Like the latter it consists for the most part of plagioclase feldspar with biotite, hornblende, augite or enstatite, and generally has a porphyritic structure with scattered larger crystals in a fine-grained ground-mass, but contains also quartz as rounded, corroded phenocrysts or grains, or as an element of the groundmass. When its structure is glassy it is known as dacite-pitchstone (see PITCHSTONE). The feldspar content of dacite ranges from oligoclase to andesite and labradorite; sanidine occurs also in some dacites, and when abundant gives rise to rocks which form transitions to the rhyolites. From this list of minerals it is readily seen that the dacites are the volcanic equivalent of the plutonic tonalites. Many of the hornblende- and biotite-dacites are gray or pale brown and yellow rocks with white feldspars and black crystals of biotite and hornblende; others, especially augite- and enstatite-dacites, are darker coloured. The name is from Dacia (q.v.), a district of central Europe, and rocks of this group occur in Rumania, Almeria (Spain), Argyllshire and other parts of Scotland, Victoria, New Zealand, the Andes, Martinique, Nevada and other districts of western North America, Greece, etc. They are mostly associated with andesites and trachytes, and form lava flows, dikes and in some cases massive intrusions in the centres of old volcanoes.

Among continental petrographers the older dacites (Carboniferous, etc.) are often known as porphyrites.

**DACRON** (TERYLENE), a man-made polyester fibre. Groundwork for its development was laid by E. I. du Pont de Nemours and Company in the 1920s. Polyesters were among the first man-made fibres developed, although the Du Pont program ultimately led to polyamides (nylon). British research chemists at Crompton Printers Association, Ltd., continued the study of polyesters and

distinction is that *thron* expresses the personality of the god and *daemon* his activity. The *daemon* is regularly applied to sudden or unexpected supernatural interventions not due to any particular deity. It became commonly the power determining a person's fate, and a man could have a personal *daemon*. An early as Hesiod the dead of the golden age became *dæmones*, and later philosophical speculation envisaged these as lower than the gods (possibly mortal) but as superior to humanity. The Christians therefore attributed the actions of the pagan gods to *dæmones*, identified as fallen angels. (H. W. P.)

**DAENDELS, HERMAN WILLEM** (1762-1818). Dutch soldier who served with distinction in the army of the Batavian republic and later ably administered the Dutch East Indian possessions, was born at Hattem, in Gelderland, Oct. 21, 1762. He became a solicitor at Hattem, where he led the anti Orangist "Patriot" movement. In 1787 he took part in the defense of Amsterdam against the Prussian intervention on behalf of the Orangists and after the defeat of the Patriots went to live in France. Joining the French Revolutionary army, he took part in the invasion of Holland in 1793. During the period of the Batavian republic he rose to the rank of lieutenant-general and twice helped to overthrow the government by force (Jan. and June 1798) in order to give it a more centralized character. In 1799 he commanded a Dutch army against the British and Russians at Alkmaar. Made governor general of the "Asian colonies and possessions" in 1807 by Louis Bonaparte, then king of Holland, he ended the financial abuses of the former Dutch East India company and built the great highway through central Java. In 1815 he was appointed governor of the Dutch possessions on the west coast of Africa. He died at Elmina, Gold Coast, May 2, 1818. (F. Dz. J.)

**DAFFODIL**, the common name of a group of plants of the genus *Narcissus*, family Amaryllidaceae. The common daffodil or trumpet narcissus, *N. pseudo-narcissus*, is frequent in woods and thickets in most parts of northern Europe, but is rare in Scotland. It is sparingly naturalized in the eastern United States as an escape from cultivation. Its leaves are five or six in number, are about a foot in length and an inch in breadth, and have a blunt keel and flat edges. The flower stalk is about 18 in. long, the spathe single flowered. The flowers are large, yellow, scented and a little drooping, with a corolla deeply cleft into six lobes and a central bell-shaped crown or corona which is crisped at the margin. This "trumpet" is at least as long as the petals. The stamens are shorter than the cup, the anthers oblong and converging, the ovary globose and has three furrows; the seeds are roundish and black. The bulbs are large, orbicular, and have a parchmentlike coat. The trumpet narcissus or common daffodil is ubiquitous in European and American gardens. Its popularity has resulted in the production of many varieties differing from the parent yellow form mostly in colour. Varieties are offered with white flowers, with pink trumpet and white petals; with orange trumpet and yellow petals; with white petals and yellow trumpet and many

DAFFODIL (NARCISSUS PSEUDO-NARCISSUS). DIAGRAM OF SECTION OF THE FLOWER. The daffodil is a native of England and is widely cultivated in America. Each stem has one yellow trumpet-shaped blossom.

COMMON DAFFODIL OR TRUMPET NARCISSUS (NARCISSUS PSEUDO-NARCISSUS).

others (more than 40), but there are none that are red or blue.

The plants are superb when masses of them are arranged in random groupings as they might be found in meadows and in woods. However, as crowding tends to reduce their bloom (many old plantings will produce only foliage).

The Peruvian daffodil and the sea daffodil are species of the genera *Hymenocallis* and *Pancratium*. (N. Tr.)

**DAFYDD AP GWILYM** (d. c. 1400-1420), the greatest Welsh poet of the 14th century, was born of a noble family c. 1320 at Brogynin, Cardiganshire. Little is known of his life, except that he visited Anglesey and Caernarvonshire and knew many prominent families in Cardiganshire. He died c. 1380. His *awdlau* (odes) and *cywyddau* (a form of short ode) show that he was trained in the Welsh bardic art and connect him historically with the native poets of the princes, but his use of certain poetic conventions proves that he was influenced by the troubadours and wandering scholars. The main subjects of his authentic poems (about 139) are nature and love, which he treats with great sensibility and wit, and unrivaled mastery of the intricate system of *cyghanedd* (q.v.).

See also WELSH LITERATURE.

**BIBLIOGRAPHY.**—I. Williams, *Cywyddau Dafydd ap Gwilym a'i Gynghrair* (Cardigan, 1913); J. I. D. Bell (1942); T. Parry, *Gwath Dafydd ap Gwilym* (1952). (T. J.)

**DAGESTAN AUTONOMOUS SOVIET SOCIALIST REPUBLIC** (DAGESTANSKAYA AVTONOMNAYA SOVETSKAYA SOTSIALISTICHESKAYA RESPUBLIKA), in the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the northern flank of the Greater Caucasus range at its eastern end and along the western shore of the Caspian sea. Pop. (1959) 1,067,472. Area 19,871 sq. mi. Russia annexed the Persian province of Dagestan in 1813, but rule was not enforced over the rebellious Khans until 1877. The republic was formed in 1921 after civil war, but from World War II to 1957 the northern part was transferred to Grozny oblast, later known as the Chechen-Ingush Autonomous Soviet Socialist Republic.

**Physical Features.**—Dagestan can be divided into five physical regions. The first, occupying most of the southern half of the republic, consists of the Caucasus mountains, there at their widest. The southern boundary of Dagestan runs along the main crest ridge, which rises to 11,962 ft. in Mt. Guton and 14,698 ft. in Mt. Bazar-Dyuul. North of the main range the Andiyski-Salatau and Giminski ranges enclose a huge triangle of extremely rugged mountains, very difficult of access. The chief ranges of this so-called Dagestan interior highland are the Bogotaki and Kikaki ranges. These mountains, of highly folded limestones and sandstones, are cut up by the deep valleys and canyons of the many rapid rivers flowing down to the Caspian, notably the Sulak (with its headstreams the Karakoyun and Andiyskoye Koyun), the Samur and the Kurakh. The canyon of the Samur as it breaks through the mountain rim, is up to 5,000 ft. deep. Rainfall is very low in the mountains, especially on south-facing slopes, and wide areas are almost treeless. Only in the valleys and canyons are there patches of deciduous forest. On the higher main range are forests of pine and birch, giving place higher up to Alpine pastures.

Secondly, north of this wild and forbidding complex of mountains, is the zone of forerland hills about 12-25 mi. wide and rising to 7,000-8,000 ft. There rainfall is much higher, from northerly and easterly winds, about 25 in. a year. This is a zone of dense cover of oak, beech, hornbeam, maple, poplar and larch trees. The lower slopes have good pasture lands and even patches of black earth with a grassy steppe vegetation.

The third region is the narrow coastal plain between the mountains and the Caspian, from 2 to 20 mi. wide, and crossed by the rivers debouching from their gorges. This plain has only recently emerged from the Caspian and is covered by marine sediments, especially sand. Petroleum and natural gas occur there.

The fourth area continues the coastal plain northward, at the narrower "waist" of the republic, and consists of the low, swampy

plain in the lower course of the Terek river and its delta. Saline swamp soils are common. The Terek and its distributaries flow between artificial dykes, 10–12 ft. above the surrounding land. Just off the delta is the long, sandy Agrakhanski peninsula.

Finally, north of the Terek, Dagestan broadens out again to include most of the rolling, sandy plain of the Nogai steppe, as far as the river Kuma, the northern boundary. In this area low, latitudinal ridges and depressions alternate. The climate is hot and dry, with only 8–10 in. of rain a year. Vegetation is thus of a semidesert character, dominated by sagebrush, developed on poor chestnut soils.

**Population.**—The great difficulty of access made Dagestan both an area of refuge and an area where peoples have developed into separate tribes, largely cut off from each other. As a result few areas of the world show such great ethnic complexity, and it is sometimes said that every valley has its own nationality and language. There are about 30 ethnic groups in all, most of which are Caucasian, Turkic or Iranian. By the 1959 census the largest Caucasian nationalities were the Avars (270,394), who include the Andi groups, followed by the Lezgians (223,129), Darghins (158,149), Laks (63,529), Tabasarans (34,700), Aguls (6,709), Rutuls (6,732) and Tsakhurs (7,321). The largest Turkic groups are the Kumyks (134,967) and Nogai (38,583), while the Tats are the main representatives of the Iranians. Only in the lowlands and towns are found Russians (about 15% of the population), Azerbaijanis, Armenians, Jews and Ukrainians. In all, 81 nationalities are distinguished. The total population in 1959 was 1,062,472, of whom 314,968 (30%) lived in the 7 towns and 6 urban districts. The chief towns are the capital, Makhachkala (119,334), Derbent (99,000), Kislyar and Buynaksk. (See also CAUCASUS, PEOPLES OF.)

**Economy.**—Dagestan is rich in minerals, including coal, iron ore and nonferrous metals, as yet little exploited, because of the difficulty of the country (the name Dagestan is a Turkic term meaning "mountain country"), but petroleum and natural gas are obtained along the coastal plain, centred on Makhachkala, Achi-Su and Izberbash. The fast-flowing rivers provide hydroelectric power. There are large plants on the Karakoysu at Gergebil and on the Terek at Kargalinskaya and about 80 small, local stations. A big plant was constructed at Kizil-Yurt on the Sulak after 1960. Glassmaking is an important industry, and there is a large glassworks at Dagestanskiye Ogni, just northwest of Derbent (the latter place is on the main railway line to Baku and is a centre for the oil fields to the northwest). But, apart from engineering in Makhachkala, other industry is largely confined to the processing of agricultural products and to traditional handicrafts, especially iron-working and carpet making. Timber is exploited, but the scale is limited by the rugged terrain.

The bulk of the population derive their living from agriculture, above all from livestock, since only 15% of the area is arable. Sheep, in particular, are kept in very large numbers. There is considerable transhumance from winter pastures on the Nogai steppe to summer pastures high in the mountains. Arable farming, where it is carried on, is usually intensive. Hillsides are often terraced, while the Terek delta and the coastal plain have many irrigation schemes, supplying water to 74% of the arable. Vineyards are extensive, especially around Derbent on the coastal plain and Kislyar in the Terek delta, while fruit and vegetables, including cherries, apricots, apples, pears, quince and melons, are grown in quantity. Subtropical fruits, pomegranates, figs and almonds are also grown and a start has been made in growing tea. Wheat and maize (corn) dominate the cereal crops, with rice in the Terek delta. Settlements along the Caspian shore engage in fishing. See also CAUCASUS.

(R. A. F.)

**DAGGER**, a hand weapon with a short blade, the diminutive of the sword. In the study of ancient times it is often impossible to distinguish the dagger from the primitive sword, and at a later date the distinction between a long dagger and a short sword is frequently vague. An excellent example is the medieval scramasax of northern Europe; its blade ranged in length from 4 to 20 in. Still later, the broad-bladed cinquedeas of 1475–1550 had almost as great a range and could be used as either swords or

TYPES OF DAGGERS FROM THE 14TH TO THE 16TH CENTURY

(A) Cinquedeas; (B) kidney dagger; (C) rondel dagger; (D) eared dagger; (E) main gauche; (F) left-hand dagger

daggers. By 1300, however, the dagger was generally recognized as a distinct weapon.

Among the European daggers of the 14th, 15th and 16th centuries, the principal types were the *quillon* dagger with a simple cross guard; the basilard, a variation of the *quillon* dagger with parallel bars for the guard and pommel; the kidney dagger with a guard formed by two lobes; the rondel dagger with disk-shaped guard and pommel; the eared dagger with a pommel formed by two disks set at an angle flaring outward; and the stiletto, usually a quillon dagger with a narrow three- or four-sided blade. These were all stabbing weapons, and since it was often necessary to penetrate armour with the blow, they were held with the blade below the hand. This limited the variety of strokes but afforded greater power.

During the 16th century a new school of fencing evolved in which the dagger was held in the left hand and used for parrying the opponent's sword, thus leaving the user's own sword free for attack. For this new use, the left-hand dagger developed. Since its principal function was parrying, it needed a large guard. In northern Europe this need was met by lengthening the guard of the *quillon* dagger and sometimes adding a ring to protect the knuckles. In southern Europe, the cross guard was lengthened, a triangular knuckle guard was added, and the widened blade was frequently notched as a further aid in entrapping an enemy's blade. This form of left-hand dagger is usually called a *main gauche* to distinguish it from its northern counterpart. Both types were held with the blade above the hand in the manner of a sword.

Because of its convenient size a dagger could be drawn quickly, worn inconspicuously and used in a confined space. Its general utility as both a weapon and a tool has made the dagger popular with both soldiers and civilians of all ages and cultures. The many varieties of specialized European daggers and the wealth of African, Asian and native American types make it impossible even to list their names in a short article. They include, for example, the wavy-bladed Malayan kris, the short curved-bladed kukri with its broad heavy point used so dextrously by the Gurkhas as late as World War II, and the Hindu katar with its flat triangular blade and cross-bar grip designed so that the user "punched" with it. Among the strictly military daggers would be the musketeer's dagger which developed into the bayonet, the artillerist's stiletto with his scales etched on the blade, and so on down through many of the trench knives of World Wars I and II.

**DAGNAN-BOUVERET, PASCAL ADOLPHE JEAN** (1852–1929), French painter of realistic scenes of everyday life, was born in Paris on Jan. 7, 1852. He studied under Gérôme at the École des Beaux-Arts, and first attracted notice by his picture "A Wedding at the Photographers" in the Salon of 1879. He

joined the movement, initiated by Bastien-Lepage in France, which took up the study of contemporary life. From 1880 onward he made Brittany with its rustic types and religious festivals his special sphere. A harmonious green tone pervades his open-air effects. He was a fine draftsman and also practised lithography. For the Sorbonne he painted a large panel representing Apollo and the Muses. Dagnan-Bouveret died at Quincey (Haute-Saône), July 3, 1929.

**DAGOBERT I** (d. A.D. 639), Frankish king of the Merovingian dynasty, was the elder son of Clotaire II. His father in 623 made him king of part of Austrasia, appointing Arnulf, bishop of Metz, and Pepin of Landen to be his advisers. Married to his stepmother's sister Gomatrude in 625 or 626, Dagobert then made his father cede to him Reims, Toul and Verdun, as having formerly belonged to Austrasia. On his father's death (629), he raised an army, marched on Soissons and made the magnates of Neustria recognize him as their king also, leaving his half-brother Charibert (d. 632) the control only of Toulouse, Agen, Cahors, Périgueux and Saintes, with orders to set up a march or mark on the Gascon (Basque) frontier. His tours of inspection in Burgundy and in Austrasia (630–631) won him a reputation for justice. He then fixed his residence in Paris, where his ancestor Clovis had had his capital. To appease the Austrasians' resentment at this move he gave them his three-year-old son Sigebert as king (634). A Gascon revolt was quelled by an army raised in Burgundy, after which the Gascon duke Aegyna came to Clichy to make his submission (637), as the Breton chief Judicaël had already done (636). The peace that he enforced within his kingdom made Dagobert respected abroad: he signed a treaty of friendship with the Byzantine emperor Heraclius (629) and was able to intervene in Spain (631), to conciliate the Lombards and to obtain by diplomacy what warfare had failed to obtain from the Saxons and from the Bohemian Wends. The historian Fredegarius, hostile to the house of Dagobert, represents him as greedy and lecherous, and debauchery may have shortened his life, but even so Dagobert was a great king whose enterprises in many respects foreshadowed those of the Carolingian rulers.

The prosperity of Dagobert's reign and the revival of the arts under him can be judged from the rich contents of the tombs of the period and from the goldsmiths' work for the churches; e.g., the Chelles chalice and St. Éloi's cross at St. Denis. The techniques of cloisonné ornamentation on gold and damascening on iron reached perfection. The reign also witnessed a remarkable increase in the number of monastic foundations, many of them sponsored by members of Dagobert's own entourage, such as his protégés the bishops Éloi (Eligius), Ouen (Audoenus) and Didier (Desiderius). Excavations in 1955 demonstrated the part that Dagobert himself played in the construction and decoration of the great basilica that was then replacing the old church at St. Denis. He was buried in it in 639, and his monument (re-erected with new sculptures in the 13th century) still stands there.

**DAGOMBA**, the Hausa name for the Dagbamba, the inhabitants of the chiefdom of Dagbon in the Northern region of Ghana, bounded on the north and south by Mamprusi and Gonja respectively. In 1960, the chiefdom incorporated 150,000 Dagomba who speak Dagbani (a Gur language); 40,000 Konkomba (q.v.), an autochthonous people; and 10,000 Akan-speaking Chakosi, originally brought in as mercenaries. The main occupation of the Dagomba is farming, the chief crops being sorghum, pennisetum, maize, yams and groundnuts. Dwarf shorthorn cattle, sheep, goats, chickens and guinea fowl are kept. The paramount chief, the Ya-Na, lives at Yendi, while the largest town is Tamale (pop. [1960] 40,443), the administrative and commercial centre for the Northern region.

Apart from Muslims and strangers, the population is divided into chiefly families and commoners. Only sons of previous paramounts may rise to the highest office, which is filled in rotation by a divisional chief of Karaga, Mion or Savelugu. The rulers,

claiming common descent with the chiefs of Mossi, Mamprusi, Nanumba and Wa, regard themselves as invaders from the north. Formerly the chiefdom extended south to the Black Volta but was reduced in size by the conquests of the Gonja in the mid-17th century. At the end of that century, the Dagomba were subjugated by the Ashanti (q.v.), who forced them to pay an annual tribute of slaves, which only ceased in 1874 when the Ashanti were defeated by British forces. See also GHANA: *The People*.

See M. Manoukian, *Tribes of the Northern Territories of the Gold Coast* (1952).

**DAGUERRE, LOUIS JACQUES MANDE** (1789–1851), French painter and physicist, inventor of the daguerreotype, was born at Corneilles, in the département of Seine-et-Oise, and died

THE GRANGER COLLECTION

DAGUERRE: DAGUERRETYPE MADE AT HIS HOME BY CHARLES R. MEADE. 1848

on July 12, 1851, at Petit-Bri-sur-Marne, near Paris. He was at first an inland revenue officer and then a scene painter for the opera. In 1822, in conjunction with Bouton, he opened at Paris the Diorama, an exhibition of pictorial views, the effect of which was heightened by changes in the light thrown upon them. A similar establishment was opened by Daguerre in Regent's Park, London; it was destroyed by fire on March 3, 1839. This reverse was more than compensated for by the success of his daguerreotype photographic process. J. Nicéphore Niepce, who since 1814 had been seeking to obtain permanent pictures by the action of sunlight, learned in 1826 that Daguerre was similarly occupied.

The two worked together on their "heliographic pictures" from 1829 until the death of Niepce in 1833. Daguerre, continuing his experiments, discovered eventually the process connected with his name. On Jan. 9, 1839, at a meeting of the Academy of Sciences, D. F. J. Arago emphasized the importance of the discovery, and Daguerre was appointed an officer of the Legion of Honour. A law of 1839 assigned to Daguerre and the heir of Niepce annuities of 6,000 fr. and 4,000 fr. respectively, on condition that their process should be communicated to the Academy. Daguerre's process, together with his system of transparent and opaque painting, was accordingly published by the government. For further information and a portrait see **PHOTOGRAPHY: History**.

See H. and A. Gernsheim, *L. J. M. Daguerre* (1956).

**DAGUR** (DAUR), a Mongolian people living in the Heilungkiang province of northern Manchuria, reportedly numbering 200,000 but probably less than 10,000. Their language, formerly thought to be Tungusic or a mixture of Mongolian and Tungus, is now known to be an archaic Mongolian dialect preserving features found in 13th-century documents. Their own name is Dagur (*dayur*), but the Manchu form Dahur is found in Latin plant names such as *dahurica*. The Russian form Daur occurs in the name of the Daur mountain range.

Russian settlers in the 17th century found Dagurs well-established in eastern Transbaikalia and the Amur region, and the first Siberian ecclesiastical mission went to them in 1682. The Chinese government, however, not wishing them to fall under Russian sway, resettled them. By the early 20th century, Dagurs lived largely in Heilungkiang, around the city of Hailar, and in the Nonni river valley near the city of Tsitsihar. Their chief occupations are agriculture, logging, hunting, stock raising and horse-breeding. The clan system prevails, and their religion is shamanistic, with some Lamaists.

The Dagur used Manchu or written Mongolian until a Dagur, Merse, devised a Latin transcription in 1920, since abandoned. There is a well-developed oral epic literature in which the works of the mid-19th-century poet Rabdan are outstanding.

According to Soviet reports, the Solon, a Tungus tribe number-

ing 17,000 in the valley of the I-li Ho (Ili river) of the Sinkiang Uighur autonomous region, were renamed Dagur in 1954 by government decree. Some western investigators, however, are skeptical that the Solon, Manchu and Sibo, so listed in censuses, still exist as ethnic groups. See also TUNGUS.

See N. Poppe, *The Dagur Dialect*, in Russian (1930); S. E. Martin, *Dagur Mongolian Grammar, Texts and Lexicon* (1961); "Dagur Mongols of the Nonni River Valley," ch. 4 of H. H. Vreeland III, *Mongol Community and Kinship Structure* (1954). (J. Kr.)

**DAHABEAH:** see BOAT.

**DAHLBERGH, ERIK JÖNSSON**, COUNT (1625–1703), Swedish soldier, civil servant and graphic artist, was born on Oct. 10, 1625. From 1655 to 1657 he served as an engineer during Charles X Gustavus' Polish campaign and in 1656 he was appointed lieutenant quartermaster. During the Danish campaign of 1658 he was present at the crossing of the frozen Belts, but though he claims in his diary to have played a decisive role it is unlikely that he did so. He became a colonel and quartermaster-general in 1674 and played an important part in the Danish war of 1675–79. In 1680 he was put in charge of fortifications in Sweden and was responsible for the building of many new fortresses and the reconstruction of others. In 1693 he was created privy counsellor, count and field marshal, and in 1696 he was appointed governor-general of Livonia. At the outbreak of the Great Northern War in 1700 he conducted the defense of Riga with great energy and repulsed the Saxon surprise attack. He retired in 1702 and died in Stockholm on Jan. 16, 1703. As a draftsman, he is best known for his illustrations to *Suecia antiqua et hodierna* (not published till 1717) and to Samuel Pufendorf's history of Charles Gustavus (1697).

**BIBLIOGRAPHY.**—E. Ericsson and E. Vennberg, *Erik Dahlbergh* (1925); G. Björlin, *Karl X Gustaf och Erik Dahlbergh vid övergången av Stora Bält* (1921); E. Carlsson, "Erik Dahlbergh och övergången av Stora Bält, *Historisk Tidskrift* (1951). (N. G. R.)

**DAHLGREN, JOHN ADOLPHUS BERNARD** (1809–1870), U.S. admiral, noted for his contributions to naval ordnance, was born in Philadelphia, Pa., on Nov. 13, 1809. He entered the navy in 1826 and saw some service in the Civil War in command of the South Atlantic blockading squadron, but he is chiefly remembered as a scientific officer. His knowledge of mathematics caused him to be employed on the coast survey in 1834, and in 1847 he was transferred to the ordnance department. Dahlgren was the inventor of the smooth-bore gun which carried his name, but was from its shape familiarly known as "the soda water bottle." It was used in the Civil War and for several years afterward in the U.S. navy. Dahlgren's guns were first mounted in a vessel which cruised under his command from 1857 until 1859. They were "the first practical application of results obtained by experimental determinations of pressure at different points along the bore . . . that is by boring holes in the walls of the gun, through which the pressure acts upon other bodies, such as pistol balls, pistons, etc." When the Civil War broke out, he was on ordnance duty in the Washington navy yard, and he was one of the three officers who did not resign from Confederate sympathies. His rank at the time was commander, and the command could be held only by a captain. Pres. Abraham Lincoln insisted on retaining Commander Dahlgren, however, and he was qualified to keep the post by special act of congress. He became post captain in 1862, rear admiral in 1863, and was in command of the Washington navy yard when he died on July 12, 1870. (D. H.)

**DAHLIA**, a genus of herbs or near-herbs of the family Compositae (q.v.), containing 18 species that fall readily into three generic sections. They are indigenous to the higher altitudes of Mexico and Central America. The first section, *Pseudodendron*, has three species, often called somewhat inaccurately tree dahlias, with rigid, erect and more or less perennial stems, these often clothed toward base with elongate, fibrous roots and in age becoming woody, very tall (even 20 to 30 ft.), internally septate at nodes but otherwise hollow or filled with a watery sap; the leaves are much subdivided and large (principal ones 2 to 3.5 ft. long). The second section, *Epiphytum*, has only one species, the anomalous *Dahlia macdougalii*, a white-flowered epiphyte growing upon

tall trees and spreading over their tops in the rain forests of Oaxaca, Mex. The third section, *Dahlia* (syn. *Neocaulon*), contains the 14 species that typify dahlias to most people. Their stems are annual, tall (to seven or eight feet or, rarely, taller) or dwarf, erect or procumbent, internally open or imperfectly septate at nodes, elsewhere solid or hollow but devoid of watery sap, not externally covered toward the base with fibrous roots; the principal leaves are under two feet long.

The dahlia was first introduced into Great Britain from Spain in 1798 by the marchioness of Bute. The species was assumedly *D.*

*pinnata*, which later was bred with *D. coccinea* to produce many of the forms now common. The cactus dahlias of today are derived from *D. juarezii*, a cultigen, doubtless a mutant, of Mexican origin.

Varieties of cultivated dahlias belong to 13 different types, the best known being: (1) single dahlias, with a disk of tubular florets surrounded by large ray florets; (2) show dahlias, with large and double flowers, quilled florets self- or pale-coloured and edged or tipped with a darker colour; (3) fancy dahlias, unlike the show in having the florets striped or tipped with a second tint; (4) bouquet or pompon dahlias, with much smaller double, quilled flowers of various colours; (5) cactus dahlias, a race with long, acicular rays; and (6) peony-flowered dahlias, with large, floppy heads, broad florets and several tubular florets in the centre.

New varieties are procured from seed, which should be sown in pots or pans toward the end of March, or placed in a hotbed or propagating pit, the young plants being transplanted into pots or boxes and gradually hardened off for planting out in June; they will flower the first summer under favourable conditions. The older varieties are propagated by dividing the large tuberous roots, taking care to leave an eye to each portion of tuber. Valuable varieties are sometimes perpetuated through root grafts. Young, nonflowering shoots are often used in making cuttings for commercial propagation. These produce tubers, good for planting the second year. Dahlias succeed best in an open situation, and in rich, deep loam, but will succeed in most garden soils if these are manured. They flower until interrupted by frost in the autumn. The tubers are not hardy, but must be stored in a cool, dry place over winter.

The name dahlia was created by the Spanish botanist Cavanilles in honour of the Swedish botanist Andreas Dahl.

See Earl Edward Sherff, "Dahlia," *North American Flora*, series 2, part 2, pp. 45–59 (1955). (E. E. Sr.)

**DAHLMANN, FRIEDRICH CHRISTOPH** (1785–1860), German historian and the first political writer of the "Kleindeutsche" (non-Austrian) party, was born at Wismar, then Swedish, on May 13, 1785. He studied classical philology at the universities of Copenhagen (1802) and Halle (1804). In 1812 he was invited to a chair in history at Kiel university, where he first entered politics as a vocal champion of the rights of the Schleswig-Holstein duchies. He left Kiel in 1829 for a chair of history in Göttingen, where he took part in forming the Hanoverian constitution of 1833. When in 1837 the king, Ernest Augustus, repudiated the constitution, Dahlmann led the famous protest of the seven Göttingen professors which, though without apparent effect, roused and concentrated popular feeling in Germany. Dahlmann was deprived of his post and banished. After some years in Leipzig and Jena, however, where he worked on his *Geschichte Dänemarks*, three volumes (1840–43), he was appointed by Frederick William IV of Prussia to a chair at Bonn university (1842).

Dahlmann made his reputation as a writer with his *Politik auf den Grund und das Mass der gegebenen Zustände zurückgeführt* (1835); but the books most significant of his own viewpoint and his place in the movement for national unity were his *Geschichte*

J. HORACE MCFARLAND CO.

FORMAL DECORATIVE DAHLIA

*der englischen Revolution* (1844) and *Geschichte der französischen Revolution*. In these works he showed a strong preference for the English form of constitution as analyzed by Montesquieu and this view and preference determined his work after 1848 on the proposed German constitution. In 1848, at Frankfurt, he was a member of the preliminary parliament and of the national assembly in the Paulskirche. He was appointed to the constitutional committee, and the draft constitution was largely influenced by his ideas. A Protestant and a northerner, Dahlmann had no emotional ties with the historic medieval empire or with Austria and he wished for the exclusion of the non-German Austrian dominions from a unified Germany. His thinking on German unity envisaged a constitutional monarchy under Prussian leadership, supported by a strong middle class. Absolutism and radicalism were alike alien to his thinking. When Frederick William IV was elected emperor by the Frankfurt assembly on March 28, 1849, Dahlmann was one of the deputation which offered him the crown in Berlin. After the king's refusal Dahlmann retired from the national assembly (May 21) and gradually from political life. He was still, however, one of the chief promoters of the Gotha conference in June 1849 and sat in the Prussian parliament (1849–50) and in the Union parliament at Erfurt (1850). He died in Bonn on Dec. 5, 1860. Dahlmann's writings influenced H. von Sybel and H. von Treitschke.

Of his other works the most important is *Quellenkunde der deutschen Geschichte* (1830), which, revised by G. Waitz and later by others, appeared in its 9th edition, under the title *Dahlmann-Waitz*, in 1931.

**BIBLIOGRAPHY.**—A. Springer, *F. C. Dahlmann*, 2 vol. (1870–72); H. von Treitschke, *Historische und politische Aufsätze*, vol. 1, 8th ed. (1918); H. Christern, *F. C. Dahlmanns politische Entwicklung bis 1848* (1921); H. von Srbik, *Geist und Geschichte des deutschen Humanismus*, vol. i (1950).

**DAHN, (JULIUS SOPHUS) FELIX** (1834–1912), German poet, jurist and historian, author of historical novels with a didactic intent inspired by the writer's attitude to contemporary issues. He was born on Feb. 9, 1834, in Hamburg. His father, Friedrich Dahn, and his mother, Konstanze Dahn (*née* Le Gay), were on the stage and the family had been connected with the theatre for several generations. Felix Dahn grew up in Munich in an intellectual and artistic atmosphere and studied law and philosophy in Munich and Berlin (1849–53). His parents separated in 1850 and the shock drove him into a solitary asceticism which remained characteristic. His *Erinnerungen* (6 vol., 1890–95) give a vivid picture of his early life as a member of a Protestant family living in predominantly Roman Catholic Bavaria and of the growth of the liberal and monistic ideas which were to inform his work. He was appointed *Privatdozent* at Munich university (1857), after publishing several works in jurisprudence, but had already begun composing verse-epics on subjects from early German history, encouraged by Theodor Fontane and influenced by de la Motte Fouqué and Graf von Platen-Hallermünde (*Harald und Theano*, 1854–55; *Die Amalungen*, written in 1857–58, published in 1876). He was appointed to a professorship at Würzburg in 1863, then moved to the University of Königsberg in 1872 and settled at Breslau in 1888, where he achieved great popular fame as teacher, lecturer and poet. His liberal principles developed strongly at this time in the direction of Bismarckian patriotism. He became rector of the university in 1895.

His work as a scholar is enshrined in a great number of books and monographs on historical subjects, the most substantial being *Die Könige der Germanen* (11 vol., 1861–1907), *Die Urgeschichte der germanischen und romanischen Völker* (4 vol., 1881–90) and *Deutsche Geschichte von der Urzeit bis 843* (1883–88). All reveal immense erudition and great imaginative insight. Many of his essays and articles were collected in *Bausteine* (8 vol., 1879–84). His historical novels enjoyed an enormous success at the time, but are not widely read today. The best is probably *Ein Kampf um Rom* (4 vol., 1876–78), where he succeeds in infusing a tense and theatrical story about the decline of the power of the Goths in Italy with a good deal of contemporary relevance. Its success led him to produce a series of similar works, treating historical subjects in an emotional way with a pedagogic aim. His first

volume of poems was published in 1857 and he produced a steady stream of poetry, mostly ballads, till the end of his life. His first marriage was dissolved. His second wife, Therese (*née* Freiin von Droste-Hülshoff), collaborated in some of his novels. His *Sämtliche Werke poetischen Inhalts* (21 vol.) appeared in 1899 and were augmented by four more volumes in 1903. He died in Breslau on Jan. 3, 1912.

**BIBLIOGRAPHY.**—H. Meyer, *Felix Dahn* (1913); biographies by C. Kollmann in *Altpreuussische Biographie*, vol. 1 (1941) and F. Martini in *Neue deutsche Biographie*, vol. 3 (1957). (W. D. W.)

**DAHOMÉY** (FON), the name of a people living in the south of the Republic of Dahomey in Africa; they speak Fōn, a language belonging to the Kwa subfamily of the Niger-Congo family of African languages. According to a Dahoman tradition, first recorded in the late 17th century, the kingdom was formed when the conqueror of a group living on the plateau of Abomey slit open the corpse of his defeated enemy, Dā, and reared his compound over it, naming it "in the belly of Dā" or *Dā-ho-mé*. The Aladahonu dynasty, which later conquered its way to the coast, continued to reign until it fell before the French in 1894.

The traditional economy of Dahomey was based on agriculture. There was considerable craft specialization, and cowrie shells used as money laid the basis for an intricate market system. Specialists included administrators, tax collectors, priests and diviners. Social structures ranged from the polygynous immediate family (*hwe*), through the extended family (*gbe*) to the totemic clan (*xenu*). Secret societies were banned, these being regarded as potential instruments of political subversion.

World view and ritual organization are complex. The offspring of an androgynous Great God (Mawu-Lisa) constitute pantheons of nature deities; there are personal gods and forces, an ancestral cult, developing out of a complicated series of beliefs in multiple souls, magic and an intricate divining system, the cult of Fa. The whole comprises a tightly integrated conceptual unity that supports the economic, social and political systems. Dahoman culture has extensive aesthetic resources in wood carving, brass working and cloth weaving. Art has both religious and secular significance, brass figurines and appliquéd cloths being symbols of wealth and high political position. There is a wealth of narrative forms and a rich musical tradition. See also DAHOMEY, REPUBLIC OF: *History*; *The People*.

**DAHOMÉY, REPUBLIC OF** (RÉPUBLIQUE DU DAHOMEY), since 1960 an independent republic in West Africa, extends from the Bight of Benin in the south to the Republic of Niger in the north, where the Niger River (*q.v.*) forms its boundary. On the east it is bounded by Nigeria, on the west by the Republic of Togo, and on the northwest by the Republic of Upper Volta. It lies approximately between latitude 6° and 12° 30' N and longitude 0° 45' and 3° 45' E. Measuring about 416 mi. (670 km.) north-south and about 78 mi. (125 km.) east-west (except toward the Niger where it widens to about 202 mi.), Dahomey is small compared with other African countries; its area is 43,483 sq.mi. (112,622 sq.km.) and its population (1964 est.) 2,244,000. The capital is Porto-Novo (*q.v.*).

**Physical Geography.**—Four regions are distinguishable: (1) the coastal belt, low, flat, and with clumps of coconut palms, an extensive sand bar forming an obstacle to the establishment of ports. Behind the sandy fringe is a depression occupied by lagoons, some interconnected (Porto-Novo Lagoon, 12 mi. [19 km.] long; Cotonou or Nokoué Lake; Ouidah Lagoon, 25 mi. long; Grand-Popo Lagoon, connected with those of Togo), but they join the sea only at Grand-Popo and at Cotonou; (2) farther north the *terre de barre* ("bar country"), a fertile clay plateau crossed by a wide marshy depression, the Lama, between Allada and Abomey. This region is flat and uniform except for some isolated hills not exceeding 1,300 ft. (400 m.); the greater part

of Dahomey forming a plain on a crystalline base, gently undulating or dominated by occasional banks of bare rocks; (3) the Atakora massif in the northwest, reaching 2,146 ft. (654 m.), a dissected quartzite plateau flanked by escarpments from which streams flow toward the sea, toward the Niger (Mékrou, Alibori), and toward the Volta (Pandjari); (4) the eastern plains, the Borgu, and the plain of Kandi, crossed by the tributaries of the Niger and sloping down to it. Apart from the Niger, Dahomey is traversed by three large rivers: the Mono, which rises in Togo and near the coast forms the frontier between Togo and Dahomey; the small Couffo flowing into the network of lagoons at Ahémé Lake; and the Ouémé (about 310 mi. [500 km.] long). The Ouémé rises in the Atakora, is joined on the right by the Zou and then divides into two branches, one discharging into Nokoué Lake and the other into Porto-Novo Lagoon.

**Climate.**—The coastal region has an equatorial climate with a steady temperature of 72°–93° F (22°–34° C). It has four seasons: two wet, one March–July and the other late September–November, separated by two dry seasons, in the longer of which appears the harmattan, a dry, cold wind from the northeast. A sea breeze is felt inland as far as Abomey. In upper Dahomey there are only two seasons, one dry and the other wet, the wet season becoming shorter toward the north (May–September). In this part the ranges are of much more consequence. A peculiarity of the country is its comparatively low rainfall, especially in lower Dahomey where in the shelter of the uplands of Togo and of Cape Three Points it is less than 39 in. annually.

**Vegetation and Animal Life.**—Except along the rivers the rain forest has largely been cleared, chiefly by the Fon, who have planted oil palms and cultivate food crops, especially maize (corn). Woodland savanna covers the crystalline rocks and the sparsely inhabited regions. In the northern part of the woodland savanna region is a national park and game reserve, the Parc National du "W," which also extends into Niger and Upper Volta. There are the usual savanna species: various antelopes, elephant, buffalo, warthog, and several carnivores including lion and leopard.

(J. D.)

**History.**—The history of the peoples of northern Dahomey has not yet been compiled. The Dahomey or Fon, who occupy the southern part, established the three kingdoms of Allada, Porto-Novo, and Dahomey, of which the name of the most celebrated was extended by the French conquest to the whole country.

Legend relates that the daughter of the king of Tado (a town on the Mono River) while on her way to draw water, was impregnated by a leopard and bore a son, who became the founder of the dynasty. His descendants settled in the 16th century at Allada and founded a kingdom (the "kingdom of Ardra" of the old maps) with which the Portuguese established contacts. At the beginning of the 17th century three brothers, Kokpon, Do-Aklin, and Te-Agdanlin, disputed the throne. The first kept Allada, the second founded Abomey, and the third Adjatché, or Porto-Novo.

The traditional date for the founding of the kingdom of Dahomey is A.D. 1625. The son of Do-Aklin, Dakodonou, enlarged his kingdom, but it was Dakodonou's son Ouegbadja (c. 1645–85) who made it into a powerful state. He continually harassed Dā or Dan, the king of a small neighbouring state, with perpetual demands for more land until Dā, exasperated, asked whether he did not wish to set himself up on his (Dā's) stomach. Whereupon Ouegbadja attacked Dā, defeated him, and took him back to Abomey, where he beheaded him and threw his body into the foundations of the palace he was building; hence the name Dahomey (*Dā-ho-mé*, "in the belly of Dā").

Desirous of establishing communication with the coast in order to obtain arms by trading with Europeans, King Agadja (1708–32), one of the sons of Ouegbadja, conquered Allada and Ouidah, where European forts were already established. Thus was constituted, within definite boundaries, the old kingdom of Dahomey, of which certain peculiar customs deserve mention.

**The Dahomey "Customs."**—These were of two kinds: the grand customs performed on the death of a king, when people were sacrificed at his grave to provide him with wives and attendants in the spirit world; and the minor customs, held twice yearly. At

the grand customs held from January to March 1791, no fewer than 500 men, women, and children were said to have been put to death. The minor customs were held periodically to replenish the dead king's train of attendants in the spirit world.

Of the victims, chiefly prisoners of war, some tied in baskets were at one stage of the proceedings taken to the top of a high platform, together with an alligator, a cat, and a hawk in similar baskets, and paraded on the heads of the Amazons (*see below*). After a speech by the king, all of them were hurled down into the middle of a surging crowd and butchered. Sir Richard Burton (*q.v.*) in *A Mission to Gelele, King of Dahome*, insisted that the horrors of these rites were exaggerated. On the death of the king the wives destroyed everything within reach and attacked and murdered each other, the uproar continuing until order was restored by the new sovereign.

**The Amazons.**—The training of women as soldiers was begun by King Agadja on the occasion of his capture of Ouidah. About one-fourth of the whole female population were said to be "married to the fetich." The most favoured were chosen as wives of the king or enlisted into the Amazon regiments; they took the post of honour in all battles. Burton, who in 1862 saw an army marching out of Kana on an expedition, computed the number of female troops as 2,500, of whom one-third were unarmed or only half armed. Their weapons were blunderbusses, flint muskets, and bows and arrows. The system of warfare was one of surprise. When the army was within a few days' march of the town to be attacked, silence was ordered and fires prohibited. Highways were avoided, the advance being by a track specially cut through the bush. The town was surrounded at night, and just before day-break a rush was made and every soul captured if possible; none were killed except in self-defense, as the object was not to kill but to take prisoners to sell at the coast in order to obtain arms.

**Gezo and the Forts.**—King Gezo (1818–58) greatly reduced human sacrifice and ordered that there was to be no general sacrifice of the palace women on his death. He also strengthened the kingdom, extending its frontiers northward. He conducted many campaigns in Nigeria against the Yoruba (*q.v.*) to obtain slaves, but his attack in 1861 on Abeokuta was repulsed. In the same year he signed a commercial treaty with the French.

A French fort had been established at Ouidah by the Compagnie des Indes in the 17th century, but its garrison was withdrawn in 1797. In 1842 a trading firm was set up in Ouidah with French authorization. British, Portuguese, and Brazilian forts there had fallen into ruin, and when the British in 1852 blockaded the coast to prevent slaving, both France and Portugal protested. In 1857 the French established themselves at Grand-Popo.

Gezo's successor Glélé or Gelele (1858–89) offended the British and French by attacking his neighbours, persecuting Dahomean Christians and encouraging the slave trade. To check his aggressions the British in 1861 annexed Lagos. In 1863 the French signed a treaty with the king of Porto-Novo and also acquired Little Popo (Anécho). By a treaty of 1868, Glélé authorized the French to establish themselves at Cotonou. The Franco-German treaty of 1885, determining the limits of German colonization on the Togo coast, gave Little Popo and Porto-Seguro to Germany. The Portuguese claimed a protectorate over the coast but retained only their old fort at Ouidah.

**French Rule and Independence.**—The establishment of the French on the coast was a source of annoyance to the kingdom of Dahomey and hindered the slave trade. The death of Glélé and the accession (1890) of his son Behanzin (1889–94) precipitated hostilities. Cotonou and Porto-Novo were attacked and some missionaries were abducted from Ouidah to Abomey. One of them negotiated the Treaty of Ouidah (Oct. 3, 1890) which recognized French protection of Porto-Novo and indefinite occupation of Cotonou, in compensation for which the king of Dahomey was to receive a pension. The treaty was adversely criticized in France and little respected by Behanzin, who soon resumed his raids. The French in 1892 mounted a fresh expedition under Col. (later Gen.) Alfred Amédée Dodds (*q.v.*). The Dahomeans were defeated, and Behanzin fled. A French protectorate was established over Abomey, where a brother of Behanzin's took his place. After

BY COURTESY OF THE SERVICE DE L'INFORMATION DU DAHOMÉY

PEOPLE OF DAHOMÉY: (LEFT) SOMBA FROM THE FAR NORTH; (CENTRE) DAHOMÉAN OF OUIDAH; (RIGHT) PEUL WOMAN FROM THE NORTHEAST

14 months of resistance and negotiation, Behanzin himself surrendered in January 1894 and was deported. The three protected kingdoms of Abomey, Allada, and Porto-Novo were absorbed into the colony of Dahomey.

In order to link the colony to their other west African possessions, the French set to work to secure the northern hinterland of Dahomey. This they achieved chiefly through the expeditions in 1895-96 of Capt. J. M. L. Baud. The convention of 1898 added the western part of Borgu to Dahomey, but did not concede access to the navigable part of the Niger, which France desired. In 1899 Dahomey was incorporated in French West Africa. On the outbreak of World War I French forces from Dahomey took part in the conquest of Togoland from Germany (August 1914).

In World War II Dahomey followed the fortunes of French West Africa (*q.v.*), adhering to the Allied cause in 1942. An overseas territory of France in 1946, by 1959 it was an autonomous state of the French Community. Independence was proclaimed on Aug. 1, 1960. In the ensuing months the republic was on several occasions disturbed by disorders, and in November 1960 a new authoritarian constitution was adopted. (See *Administration and Economy* below.) (Hu. De.)

In 1961, under the leadership of Hubert Maga, Dahomey moved toward a single-party system of government. In October 1963 the army seized power and Col. Christophe Soglo became head of a new government. In January 1964 Sourou Migan Apithy and Justin Timotin Ahomadegbé were respectively elected president and vice-president after a constitutional referendum. The officers who led the revolution the previous October were promoted.

After a boundary dispute between Dahomey and Niger in December 1963, Niger announced its intention of expelling all Dahomean citizens. Dahomey retaliated by closing all roads and railroads into Niger. The quarrel was settled after the intervention of the Union Africaine et Malgache, but broke out again in November 1964 when Dahomey was accused of granting political asylum to political refugees from Niger. A conference held at Cotonou in May 1964 considered the possibility of creating a regional economic union between Ghana, Togo, Dahomey, and Nigeria.

Continuing economic and political difficulties in Dahomey culminated in November 1965 in the overthrow of the government by the army commander, Soglo (now a general); both Apithy and Ahomadegbé were relieved of their posts. (X.)

**The People.**—Apart from a few Nago of the Yoruba family along the frontier and some Popo and Mina fishermen along the coast, southern Dahomey is inhabited by the Fon or Dahomey (*q.v.*), a patrilineal people who established the kingdom of Dahomey and the neighbouring states and who make up about half the total population. Like other members of the Kwa linguistic group (Ashanti, Ewe, Yoruba) the Fon developed an advanced civilization with full clothing, plastic arts, and a composite religion

in which secondary gods, monasteries, secret societies, and divination were prominent. Their northern neighbours, the Chabe (Tshabe) and Itsha, also speak Kwa dialects.

Farther north live a large number of small tribes collectively known as Somba, paleonegritic naked cultivators who hunt with poisoned arrows and have no political organization. To the northeast, in the Borgou, are the Baroba, who speak a language related to Songhai and were formerly organized in kingdoms. Their civilization is of Sudanese type. Islam has made some progress in this region, where some nomad Fulani (*q.v.*; or Peuls) are also found. The other peoples are pagan and adhere to animistic religions, but Christianity has

(Hu. De.)

made important progress among the Fon.

**Administration and Economy.**—The first constitution was adopted in February 1959 following a popular referendum, and was replaced by a second constitution adopted by the national assembly in November 1960. French is the official language. A legislative assembly elected for five years by direct vote elects a prime minister, who himself appoints the members of his council, holds executive power, and is responsible to the assembly. In 1959 was created the *conseil de l'entente*, a cooperation agreement between Ivory Coast, Niger, Upper Volta, and Dahomey; it provided for a full customs union and a common fund of capital on which each country might draw.

There were in the early 1960s more than 500 public and private primary schools, about equally divided. Secondary schools numbered 22 and there were 8 vocational schools.

**Economy.**—Most of the Dahomean peoples are good cultivators, although often primitive. In the south, the chief subsistence crops are maize (corn) and cassava. The peoples of northern Dahomey (especially the Somba in the Atakorás) prefer to grow large and small millet (*fonio*), supplemented by sweet potatoes and yams. The Ouémé Valley development scheme is the largest single project for the improvement of agriculture.

The main wealth of the country derives from the oil palm. The palm plantations over the plateau of the *terre de barre* and around Porto-Novo, Athiémé, Ouidah, and Abomey cover more than 2,000 sq.mi. and are continually replanted. The palm oil is extracted locally in modern mills and the crushed kernels shipped to France for extraction of the palm-kernel oil. Other exports are copra from the coastal region, cotton (a modern introduction), shea nuts, coffee, and peanuts, grown around Abomey and Parakou and in the Kandi plain. Fishing in the lagoons and rivers is more important than in the sea; fish (dried and smoked) are largely exported to Nigeria and Togo.

Minerals exist but have been little exploited. Chrome has been found in the Natitingou district in the northwest, and the iron ore of the Atakorás has long been known and was formerly worked by the Africans. Easily worked iron deposits of high quality also exist around Kandi. Their distance from the coast has discouraged the exploitation of these mineral resources, as also that of the titanium-bearing alluviums in the centre and north of the country. Ilmenite was discovered on the coast in 1958. Industry is insignificant except for oil mills, ginning plants for cotton and kapok, and soap factories at Porto-Novo, Cotonou, and Ouidah. From the 1950's Cotonou tended to replace the administrative capital Porto-Novo as the chief port and commercial centre. Other towns are Abomey, Ouidah, Parakou, and Djougou.

**Communications.**—Dahomey has nearly 2,500 mi. (about 4,000 km.) of roads and 750 mi. (1,200 km.) of tracks, but the three metre-gauge railways of the Benin-Niger system, which start from

Cotonou, total only 360 mi. (580 km.) and are always in deficit. The principal line runs north to Parakou. Airlines link Cotonou with other main centres in west Africa and with France.

**DAILLÉ (DALLAEUS), JEAN** (1594-1670), French Protestant theologian, was born at Châtellerault and educated at Poitiers and Saumur. From 1612 to 1621 he was tutor to two of the grandsons of Philippe de Mornay, seigneur du Plessis-Marly. Ordained to the ministry in 1623, he was in 1625 appointed minister of the church of Saumur and in 1626 of the church of Charenton. Of his works, which were principally controversial, one of the best known is the *Traité de l'emploi des saints pères* (1632), in which he denied the authority of the Church Fathers. In his *Sermons* on the Philippians and Colossians, Daillé vindicated his claim to rank as a great preacher as well as an able controversialist. He was president of the last national synod held in France, which met at Loudun in 1659, when he defended the universalism of Moïse Amyraut. He wrote also *Apologie pour les Églises Réformées* and *La Foi fondée sur les saintes écritures*.

**DAIMLER, GOTTLIEB** (1834-1900), German mechanical engineer and inventor who patented one of the first successful high-speed internal-combustion engines and was also among the first to use gasoline as fuel, thereby making the engine available for automotive purposes, was born at Schorndorf in Württemberg, March 17, 1834. He attended the polytechnical school in Stuttgart and worked in England and Germany before he became technical director, working on a high-speed four-cycle engine, for the Gasmotorenfabrik Deutz in Cologne. In 1883 he founded an experimental workshop at Cannstatt, where he developed the internal-combustion engine and used it on a bicycle (1885), a four-wheeled vehicle (1886) and a boat (1887). After selling the French rights to his patent to the firm of Panhard-Levassor, with whom Carl Benz (q.v.) had become associated, Daimler founded the Daimler Motor Co., at Cannstatt in 1890; the firm's manufactures included Mercedes (later Mercedes-Benz) automobiles. Daimler died at Cannstatt on March 6, 1900.

**DAIMYŌ (DAIMIO)**, the term used to designate the largest of the landholding magnates in Japan from approximately the 10th century onward. During the 16th century the term became limited in application to territorial lords with lands assessed at 10,000 koku (one koku equals 5.2 bu.) or more of annual grain production. In the term, *dai* means large and *myō* signifies "name-land" or private land. As the 8th century system of public domain broke down, private holdings (*myōden*) of various sorts came into being. These holdings were first consolidated into estates (*shōen*) organized under the authority of the civil nobility and religious establishments and remained within the framework of imperial government. As the military class (*buke*) became differentiated during the 11th century, private holdings of the warriors were interrelated with superior-inferior relationships among the *buke*. It is this phenomenon which has given rise to the analogy between European feudalism and Japanese society after the 12th century. The term daimyō has been applied only to the military or "feudal" territorial magnates.

Historians regard the history of the daimyō in Japan in three stages. During the 14th and 15th centuries the *shugo-daimyō*, serving as military governors (*shugo*) under the Ashikaga shogunate, held legal jurisdiction over areas as large as provinces. Their own private holdings were quite limited and their finances depended in part on dues from estates held by the court families and temples. After 1467 the country dissolved into a state of general warfare during which new local powers (*sengoku-daimyō*)

created, through warfare, small but consolidated domains in which all territory belonged to themselves or was held in fief by their vassals. During this time the lands of the old court were absorbed by the *buke*. The *sengoku-daimyō* built castles in the hill country from which they controlled their vassals, who likewise were petty landholders with castles. In the 16th century these daimyō fought among themselves, creating larger and larger domains. In 1568, Oda Nobunaga began the movement of military conquest over the daimyō that was later carried on by Toyotomi Hideyoshi and completed in 1603 by Tokugawa Ieyasu (q.v.). By this time roughly 200 *kinsei-daimyō* had been brought under the hegemony of the Tokugawa house, the head of which served as shogun (q.v.). By 1869 the number of daimyō had increased to 272.

The daimyō of the Tokugawa period served as local rulers in the three quarters of the country not held as granary land (*tenryō*) by the shogun. Daimyō were joined to the shogun by oath and received their lands as grants under his vermilion seal (*shuin*). Daimyō were classed according to their relationships to the shogun as kinsmen (*shimpan*), former housemen (*judai*) and allies (*tozama*). As of 1865, there were 23 *shimpan* holding an aggregate of 2,679,000 koku, 145 *judai* with 6,176,000 koku, and 98 *tozama* with 9,834,700 koku. Shogunal lands amounted to 6,800,000 koku. The balance among these various classes of daimyō holdings and the shogun's own territory became the basis of the long, stable Tokugawa hegemony.

The *kinsei-daimyō* differed from their predecessors in being more nearly petty monarchs within their domains. Their own housemen were no longer holders of outlying castles but had been drawn off the land and brought into garrison residence at the daimyō's own great castle, which alone stood at the centre of the domain. The daimyō divided his domain between his granary land and the land on which his chief housemen were enfeoffed. Normally his granary land amounted to from 30% to 40% of the whole. The daimyō's housemen were divided between fief holders (*chigyō-dori*) and salaried retainers (*kirimai-dori*), the former numbering from 10% to 15% of the latter. But all daimyō worked to convert their enfeoffed vassals to the salaried status, and by the 18th century most fiefs had been absorbed under the daimyō's expanding authority.

The daimyō used his band of housemen (*kashindan*) to administer his domain. A council of elders (*karō*) held the responsibility for policy and superintendence of other officials, among whom were the heads of military units, superintendents of the castle town, rural administration, finance, security, works, religious affairs, education, a secretariat and many other specific posts. Taxes were collected primarily in kind but domains maintained active trade with the two chief entrepôts of Osaka and Edo. Within their domains the larger daimyō had considerable freedom even to the point of issuing their own paper currency with the shogun's permission.

Daimyō came under the centralizing influence of the shogunate (*bakufu*) in two chief ways. Required to alternate their residence between their domains and Edo, they became involved in the cosmopolitan life of the shogun's court. Secondly, since *bakufu* law took precedence within the country, domains adopted the general principles of Tokugawa law and bureaucratic procedure.

By the end of the Tokugawa regime, the daimyō had become removed from the actualities of government, serving as aristocratic figureheads in their domains. This in part accounted for the success of the effort to abolish the daimyō. In 1868 the *bakufu* was abolished and in 1869 the daimyō were obliged to turn back their land patents to the emperor, being made governors (*chihanji*) of territories corresponding roughly to their former domains. In 1871 the domains were abolished and the former daimyō converted into a pensioned nobility residing in Tokyo.

(J. W. H.)

**DAINGERFIELD, ELLIOTT** (1859-1932), U.S. painter, best known for his religious pictures and evanescent landscapes, was born at Harpers Ferry, Va. (now W.Va.), March 26, 1859. He received his early education at Fayetteville, N.C., and went to New York city in 1880 to study art. He exhibited first at the

National Academy of Design in 1880. Among his best-known pictures are "Christ Stilling the Tempest," "Slumbering Fog," "Storm Breaking Up," "The Child of Mary" and "The Midnight Moon." He executed the beautiful mural decorations in the Lady chapel of the Church of St. Mary the Virgin, New York city. He won the Clarke prize of the National Academy of Design, 1902. Daingerfield was the author of monographs on George Inness (1911) and on R. A. Blakelock (1914). He died Oct. 22, 1932.

**DAIREN (TA-LIEN)**, a modern Chinese seaport city on the south coast of the Liaotung peninsula in south Manchuria. It was first developed as a seaport by the Russians in 1898 to be the terminus of the Siberian railroad and was opened to commerce in 1901. The city is usually grouped with Port Arthur (Lü-shun) and called Luta in Chinese. After the Russo-Japanese War (1904-05) when it was occupied by the Japanese, the Luta area was transferred to Japanese control and became the Kwantung leased territory. Following World War II, Lü-shun was set up in 1945 as a joint Soviet-Chinese naval base area, but Ta-lien was put under Chinese administration. On Sept. 15, 1952, the People's Republic of China and the U.S.S.R. agreed that Lü-shun would remain a joint naval base until the signing of a peace treaty between Peking and Tokyo. However, in 1955 all Soviet troops were withdrawn from Lü-shun. The urban population in the Luta region in 1958 was about 1,590,000, including 1,000,000 in Dairen. Ta-lien's population in 1938 was 515,743 of whom 351,919 were Chinese, 158,223 Japanese and 3,900 Koreans.

Ta-lien is the leading port in northeast China and one of the first-rate harbours of China. The port is sheltered by a mole 2½ mi. long, and can accommodate ships up to 20,000 tons along a row of piers extending about 3 mi. The port is well equipped with wharves, dry docks, warehouses and special loading facilities for coal and oil. It has a wide, deep and ice-free harbour. It is one of the leading shipbuilding centres of China, where 10,000-ton ocean-going vessels have been constructed. Extensive storage facilities are provided for soybeans, the principal export. In addition, it is a centre of machinery manufacturing, including railway cars, streetcars, cranes, electrical and mining equipment, machine tools, precision instruments, chemicals, cement and textiles. A petroleum refinery is also located there. (KN. C.)

**DAIRY INDUSTRY.** The dairy industry embraces the production of milk and its preparation for sale as well as the manufacture, distribution and marketing of dairy products. This article deals with the development of dairying as an industry. For additional information about milk and milk products the reader is referred to the separate articles on BUTTER; CHEESE; CASEIN; ICE CREAM; and MILK. For agricultural aspects of dairying see also the articles AGRICULTURE; CATTLE; and GRASSLAND. The role of dairying in the economy of various lands is dealt with in the articles on individual states and countries, as AUSTRALIA, COMMONWEALTH OF; DENMARK; NEW YORK; WISCONSIN.

### DAIRY PRODUCTS

Milk provides nearly all of the nutritive factors essential to a good diet. These are combined in the proportions and amounts needed for the growth of infants and children and the promotion of nutritive welfare in the adult. Milk contains about 3.9% butterfat, 3.5% protein, 4.8% milk sugar and 0.7% minerals, as well as vitamins. In buttermaking, cream, which contains a concentration of the tiny fat globules of milk, is agitated (churned) under suitable conditions until the fat globules clump together. The resulting product, butter, contains from 80% to 85% milk fat, less than 1% protein and about 16% water. A small amount of salt may be added. In cheese making most of the protein and milk fat are collected from the liquid portion of the milk. Different procedures in manufacture produce dozens of kinds of cheese. A typical cheddar cheese contains about 32% milk fat, 24% protein and 5% minerals. Removal of water by evaporation under controlled procedures is the basis for the preparation of sweetened condensed milk, evaporated milk, dried milk and sterile concentrated milk (see FOOD PRESERVATION: *Drying and Dehydration*). If water equal in volume to that removed is added to these latter products, milk with essentially the same food value as the original

product is obtained. Cream and some form of concentrated milk, e.g., condensed milk, together with cane sugar, gelatin and a stabilizer are mixed and frozen to form ice cream. To ice-cream mixes may be added such food products as fruits, nuts and chocolate. A typical commercial ice cream may contain 13% milk fat, 10% solids other than fat and 14% cane sugar. Other frozen-milk products include sherbets, ices, custards, ice milk, etc. When cream is separated from milk, the remainder, known as skim milk, contains the same components as the milk except for the fat. Skim milk, in addition to consumption by humans, is fed to young farm livestock and casein made from skim milk is extensively used in industry. Dried skim milk (nonfat dry milk) is used in meat, bakery and confectionery products as well as in the household. Buttermilk, the liquid remaining after removal of butter in the churning process, is essentially the same in composition and food value as liquid skim milk.

### MILK PRODUCTION

**History.**—The earliest historical records note the keeping of cattle, goats and sheep for the production of milk, butter and cheese. From southwest Asia, the area of first domestication of herd animals, the custom of using milk and milk products as food for man spread to other countries. Dairy cattle thrive best in areas where pasturage and other green forage are grown in abundance. Extremely cold climates are not suitable because of the lack of green forage and the great expense of protecting the animals from the weather.

Modern dairy farming is recent in origin. At first, dairy cows were kept to furnish milk for the farm family. The marketing of milk began when customers called at the farm or farmers distributed their milk directly to users. These practices still exist but the volume of milk sold in this manner in countries where dairying is most advanced is relatively small. Within the past 100 years advances along five different lines have caused milk and milk products to become important articles of commerce: (1) The factory system of processing milk was inaugurated about the middle of the 19th century, resulting in greater uniformity of product than was possible under farm processing. (2) About the same time a method was developed for concentrating milk and sealing it in containers in sterile condition. Approximately 25 years later the distribution of milk in glass bottles was begun. Many other technological advances followed. (3) The first milk sold in towns and cities came from nearby farms. The coming of refrigeration (*q.v.*) not only aided in keeping milk fresh for a longer time than formerly but also made possible the shipping of dairy products to all parts of the world. (4) An early method of transporting milk to large cities was to ship it on railways. Motor vehicles and paved roads made possible the supplying of fresh milk to markets hundreds or even thousands of miles distant from the farms where the milk is produced. A development of the second half of the 20th century was the greatly expanded use of bulk cooling tanks on farms from which tank trucks made direct pickups. (5) The wide adoption of pasteurization and the enforcement of laws requiring proper food value in dairy products greatly benefited the entire dairy industry.

**Herds.**—For reasons of economy of production, most dairy farmers who sell milk employ only dairy-cattle breeds or strains of beef cattle which have been developed particularly for their milk-production qualities. Well-defined dairy breeds are found in most European countries. Outstanding dairy breeds of European origin which have become numerous outside their homelands are the Ayrshire from Scotland, Brown Swiss from Switzerland, Holstein-Friesian or Holstein from Holland and Friesland (known in some countries as Holland or Friesian) and Guernsey and Jersey from the Channel Islands. These are the predominant dairy breeds in North America, South America, South Africa, Australia and New Zealand. Milk from species other than cattle (buffaloes, goats and sheep) is relatively small in volume (11% of the total) and is largely consumed in or near the community in which it is produced. Some goat and sheep milk enters trade channels, mostly in the form of cheese.

**Breeding and Herd Improvement.**—About the middle of the

18th century, farmers of Great Britain began the improvement of cattle and other farm livestock. The chief practices followed were the mating of related animals and close culling. Breeders of dairy cattle early recognized the value of production records as guides to herd improvement and each of the dairy cattle registry associations in the United States opened an "advanced" or "official" registry division for recording and publishing milk yields. These tests are limited to registered cattle.

A cow-testing association for obtaining production records of any dairy herd was first established in Denmark in 1895 and such organizations are common in all dairy countries. The plan was introduced into the United States in 1905. The work is supervised by the United States department of agriculture in co-operation with the state agricultural colleges and is known as the national co-operative dairy herd improvement program. Three plans of testing are carried on. Under the standard dairy herd improvement association program, a supervisor spends one day each month with each herd. The supervisor weighs the milk produced and the feed consumed by each cow and tests a sample of each cow's milk by the Babcock method (*see* BABCOCK, STEPHEN MOULTON). That day's production is used as the average for the month. A yearly summary is reported to the state agricultural college and to the United States department of agriculture. Identification records are maintained for use in the proving of sires. Under the owner-sampler plan, the farmer takes the milk weights and samples and the supervisor completes the records. In the weigh-a-day-a-month plan, the farmer records milk weights for the individual cows and feed records for the herd. In the second half of the 20th century about 1,500,000 cows or nearly 6.5% of all milk cows in the United States were enrolled in 1,700 standard dairy herd improvement associations. These cows produced at a rate of about 9,700 lb. of milk containing 380 lb. of butterfat as compared with 6,000 lb. of milk and 240 lb. of fat as a national average.

Production records of standard dairy herd improvement associations were used in progeny testing; *i.e.*, dam-daughter comparisons and the proving of sires. In a typical year 4,586 sires were proved. After about 1940 the program of artificial breeding of dairy cows was greatly expanded. In a single year in the second half of the 20th century, 675,000 herds having a total of 6,000,000 cows were enrolled in artificial breeding work. Over 2,600 superior bulls, of which slightly more than one-third were proved sires, were in service. Programs of herd classification were given much attention by breeders of registered dairy cattle. In these programs official inspectors score each animal according to the official score card for the breed. Registration of low-scoring animals is restricted. Scientific investigations of the possibility of improving herds through hybridization and also through the transplanting of eggs of a superior cow to inferior cows for incubation were under way. (*See also* ANIMAL BREEDING.)

**Feeding.**—Points which are stressed in the feeding of cows for high milk yields are liberal feeding throughout the year with especial attention to improved pastures; high-quality hay from legume or grass-legume crops; the use of good-quality silage; and supplementing the roughage with grain mixtures whenever justified by price conditions. Pasture investigations have shown increased returns from heavy fertilization and such management practices as the use of legumes and heavier-yielding grasses in pasture mixtures, alternate or rotational grazing and, in some cases, hauling the chopped green forage to the herd. Hay quality was improved by the employment of conditioners which crush the stems and promote rapid field curing and by barn drying with forced draft of unheated air or of artificially heated air. Field baling and field chopping of hay increased in popularity (*see* CROP DRYING AND PROCESSING). Silage made from legumes and grasses, as well as from corn and sorghums, received much attention in the second half of the 20th century, with trench- and bunker-type silos finding increased use. Pelleted feeds were under investigation. Concentrate mixtures consisting of ground farm grains, protein supplement (*e.g.*, soybean meal, cottonseed meal, linseed meal) and minerals, with a total protein content of 13% to 18%, were commonly fed in proportion to milk yields. Antibiotic and chemical preparations used as growth or fattening stimulants for other

classes of livestock had but limited place in the feeding of dairy cows because of their possible passage into the milk.

New Zealand dairy cows subsist mainly on grass pastures, hay and grass silage. The farms are small and heavily stocked, 50 or more cows being kept on 100 ac. Average herd size in the second half of the 20th century was 59 cows. Jersey cattle predominate. Herd improvement associations and artificial breeding programs are in operation. Yields of butterfat per cow are moderate but yield per acre is unusually high, ranging from 150 to 200 lb. on farms where grasslands are heavily fertilized. Airplanes are extensively used in fertilizing, seeding and spraying pastures.

Dairy farming in Denmark and the Netherlands is characterized by small farms, intensive cultivation of the soil, heavy stocking with cows and high production per cow. Pastures supply much of the feed for five to six months of the year. Winter feeds are mangels, hay, straw, silage and concentrates. Danish farmers have been leaders in keeping production records, in selecting cattle by type and in artificial breeding of their herds. The principal dairy-cattle breed in Denmark is the Red Danish and in the Netherlands the Holland or Friesian, a breed having both black-and-white and red-and-white types. (*See also* FEEDS, ANIMAL.)

**Milking.**—Dairy cows commonly calve at 2 to 2½ years of age and thereafter at about 12-month intervals. Usually they are milked for nine or ten months of each year. The milk produced during the first three or four days of the lactation is unfit for sale and is fed to the calf. From that time on, most of the milk not consumed by the farm family is marketed. Less than 3% of the milk produced in the United States is fed to calves. Milking in small herds is done by hand but in the larger herds nearly all of it is done by suction machines. Morning and evening milking is the general practice except in the case of unusually high-producing cows which may be milked three or four times daily. In some European countries cows in summer are milked while at pasture.

**Disease Prevention.**—Serious losses in dairy-cattle herds may be caused by tuberculosis, foot-and-mouth disease, anthrax and brucellosis (*qq.v.*) and by mastitis and calf ailments. In the United States bovine tuberculosis has been nearly eradicated because of a testing program carried on by the federal government since 1917. Rare outbreaks of foot-and-mouth disease and of anthrax have been brought under control promptly. Mastitis is an infectious disease of the udder. Reduced milk yields and unprofitable cows often result. The disease is combated by a strict sanitation program together with injection of antibiotics and other compounds into the teat canal. Brucellosis or Bang's disease has been reduced greatly in extent in the United States through a federal-state program begun in 1934. The disease causes abortions and reduced milk yields and is one of the sources of undulant fever in man. Dairy calves are beset with pneumonia, scours or diarrhea and other ailments, most of which can be prevented wholly or in part by good management.

#### DAIRY MACHINERY AND MANUFACTURING PROCESSES

The development of modern dairy equipment has been influenced by: (1) increased labour costs; (2) increased milk production; (3) increased size of farm units; (4) general adoption of pasteurization; (5) improvement in fabrication of metals, particularly stainless steels; (6) improvement in mechanical refrigeration equipment; (7) improvement in transportation facilities, equipment and roads; (8) increase in restrictions imposed on dairy farmers and dairy plants by boards of health. Comparable changes have occurred in the dairy industry in Europe and in the U.S.

**History.**—Through many centuries improvement in techniques and equipment for the handling of dairy products took place slowly. Until recent times, little or nothing was known of sanitation and the proper care of perishable foods. Because milk soured and spoiled quickly, cows and goats were driven from house to house, milked at the door, and the milk placed in the customer's receptacle. This practice still is followed in some regions.

Milk was often unsafe to drink unless it was boiled, an objectionable procedure because of flavour and composition changes. Infectious diseases, including bovine tuberculosis, were sometimes

transmitted through raw milk to humans, especially children. There are two safeguards against these diseases, namely, pasteurization of dairy products, initially used about 1895, and the eradication of tuberculosis from cattle herds by means of tuberculin-testing programs.

For good keeping quality, milk must be cooled immediately after it has been drawn from the cow. Until recent years, the common method of cooling milk was to place the containers in a tank of cold water, followed by hand stirring of the milk. In some cases, ice was added to the water.

Flowing spring water was especially prized for cooling milk and cream and springhouses for this purpose were common in the early history of the United States. The milk house or well house usually surrounded or was adjacent to the farm well.

Up to the early part of the 20th century, when milking machines came into use in the larger herds, nearly all milk stock was hand milked. When hand milking a cow, the milker sits on a low stool on the right side, holding a pail between his knees. Grasping two teats at a time, he firmly but gently squeezes and pulls downward and then releases the pressure, repeating at rapid intervals. The operation is best completed quickly and quietly without disturbing the cow.

Open-top pails were in general use for hand milking until early in the 20th century when covered pails were put into use on some farms. These pails were of two types, one being completely covered but having a small, circular, fine-mesh screen fitted into the top and the other having a solid metal cover containing a small opening. The use of these pails reduced the amount of dust, dirt and other foreign matter falling into the pail during milking.

The earliest churns were goatskins or any simple container in which cream could be agitated. A type widely used in farm homes and small dairies was the dash churn. This consisted of a tall, narrow, nearly cylindrical wooden or stone tub with a capacity of five to ten gallons. The tub was fitted with a wooden cover and cream was agitated by means of a hand-operated vertical wooden plunger or dash.

Another popular churn for home use was shaped like a small barrel and mounted in a framework. Operation of a hand crank caused the barrel to revolve end over end.

A simple but effective hand ice-cream freezer comprised a covered cylindrical metal container of two to four quarts capacity which was placed in a wooden tub. Inside the metal container was a stirrer and this was connected to a gear and hand crank arrangement fitted to the top of the tub. Freezing of the ice-cream mix was effected by surrounding the metal container with a mixture of ice and salt and turning the crank.

Creameries for making butter were established in several European countries and in the United States shortly after the middle of the 19th century. At first farmers delivered whole milk to the factory where the cream was separated by gravity after the cooled milk had stood overnight. In some areas farmers set the milk in narrow, deep cans or in pans to separate it and a hauler followed a regular route to gather the cream. The wide adoption of

farm-size centrifugal cream separators revolutionized and greatly

expanded cream production and brought an increase in the number of creameries.

Beginning in the 1940s, creameries became large-volume, general-purpose factories, purchasing whole milk and producing the milk products most in demand, including bottled milk, butter, cheese and dried skim milk. In great contrast to the early-day, locally owned small units, most creameries in the second half of the 20th century were either controlled by large national dairy corporations or were members of large farmer-owned co-operative organizations.

**Milking Machines.**—The need to increase efficiency and to reduce labour costs on dairy farms extended the use of milking machines. One manufacturer estimated that in the second half of the 20th century more than 98% of herds having ten or more cows were being milked by machine.

The milking machine has been developed to imitate the suction of the calf on the cow's teats and research has demonstrated that machine milking can be as satisfactory as that done by hand. Introduction of the separate milking room or parlour and pipeline milking have improved the sanitary conditions under which milk is handled on the farm (see FARM BUILDINGS). The milking parlour is generally used when the cows are not housed in a stanchion barn, but are allowed to run loose. The cows enter the parlour, their flanks and udders are washed and dried, and then the cows are machine milked as they are fed grain. Two to five cows can be milked simultaneously under these conditions. The cows are in the parlour five to eight minutes. In pipeline milking, which has eliminated the manual transportation of milk from the barn or parlour to the milk house to be cooled, the milk is drawn by vacuum through glass, stainless-steel or plastic pipes to the bulk cooler after it is released from the milker bucket in which it is weighed.

**Milk Coolers.**—Milk must be cooled quickly to 50° F. or below and kept cold while it is stored on the farm in order to prevent rapid bacterial growth. The simplest and cheapest method of cooling milk is to immerse ten-gallon cans of milk in cold water. Before mechanical refrigeration units were available, ice was used in some areas to provide cold water, but usually milk was cooled only to the temperature of the well water on the farm. Bulk milk tank coolers are a corollary to pipeline milkers. In this type of installation milk is drawn by vacuum through pipes from the milking machine to the stainless-steel cooling tank, which may hold 200 to 500 gal. of milk. Mechanical refrigeration is required to cool the milk and maintain its temperature at 40° F. With this system milk cans are completely eliminated. As a further saving, when local health departments permit, milk is collected only every other day.

Milk is transported from the farm to the dairy plant in stainless-steel tank trucks that hold 1,000 to 2,500 gal. of milk. Mechanical equipment has tended to make the dairy farm unit larger and to encourage greater operating efficiency.

**The Cream Separator.**—The mechanical separator has re-

placed gravity systems of separation of milk as a means of securing cream because the speed and completeness of separation are much greater.

The essential feature of the centrifugal separator is a rapidly revolving bowl which contains a series of disks. The bowl is mounted on a spindle underneath the supply tank which holds the milk. Milk enters the bowl through an opening at the top and is distributed to the disks through a series of openings known as the distributor. Thin films of milk are generated as the whole milk is forced out between the disks. The milk immediately assumes the speed of the bowl, which is turning at 6,000 to 8,000 r.p.m., and cream separation begins immediately. The heavier skim milk is thrown to the outer edge of the bowl and is led off through the skim-milk opening at the top. The cream, being lighter in weight, is concentrated in the interior and moves up to the cream outlet near the centre of the bowl. Machines which operate efficiently will leave in the skim milk less than .01% fat as determined by the Babcock test.

**The Milk Clarifier.**—This machine also uses centrifugal force in accomplishing its purpose in dairy-plant operations—that of clarifying or removing extraneous matter from milk. The clarifier resembles the separator with the exception of the bowl, which is constructed so that there will be no cream separation in the milk. There is a greater distance between disks and the inside of the bowl. The milk flows through the rapidly revolving bowl and out a single outlet.

**Pasteurizers.**—Milk and milk products are pasteurized to make them safe, that is, pathogenic organisms are destroyed by the process and keeping quality is prolonged. In general, there are two types of pasteurizers: (1) vat or holding equipment which heats milk to 145° F. for 30 minutes; (2) high-temperature short-time (HTST) or continuous-flow equipment which processes milk at 161° F. for 15 seconds. Vats are made of stainless steel with a double-walled jacket and are either rectangular or round in shape. They are equipped with a tight-fitting cover, an agitator and a recording thermometer. Either steam or hot water is circulated in the double-walled jacket as the heating medium and cooling is accomplished either by circulating cold water in the jacket or by pumping the product over a separate cooler.

**Bottling.**—At one time milk was dispensed from 10- or 20-gal. cans by the seller into the consumer's container whether it was a bucket, jar, pan or pitcher. In the United States this method of selling milk has long been outlawed. Milk containers must be automatically filled and sealed by machine in the milk plant following pasteurization and cooling of the milk. Milk was bottled in glass containers almost exclusively for many years. Glass bottles were easily sterilized and the customer wanted to see the cream layer on the milk. Since the acceptance of homogenized milk, single-service paper containers have become widely used. The increased sale of milk through stores has favoured paper containers because of lower delivery expense and the elimination of the need for bottle return.

**Buttermaking.**—The first step in the manufacture of butter is

the concentration of the fat of milk into cream by the cream separator. The first cream separators developed were factory-sized machines. Whole milk had to be delivered to the plant by the producer, who was also required to haul the skim milk back again for feeding purposes. Soon farm-sized separators were built and from 1915 to 1940 were used extensively. Then the farmer delivered sweet or sour cream to the creamery and kept the skim milk at home to feed to calves, poultry or hogs.

After 1940 there was a trend toward the return of shipping whole milk to creameries, which had become larger and more diversified in their operations. A further change also occurred: the entire product was utilized for human food. The cream is churned into butter, the sweet-cream buttermilk is dried and used by bakers and ice-cream manufacturers and the skim milk is dried and utilized in many ways for human consumption.

Pasteurization of cream for buttermaking is essential. In fact, the butter industry was the first branch of the dairy industry to use heat treatment to prolong the keeping quality of the product. Denmark in 1898 required that all cream for buttermaking be pasteurized. Although pasteurization was not made mandatory in the United States, buttermakers soon adopted the practice because it destroyed the enzymes which caused the butter to develop rancidity.

Cream is churned into butter in a revolving barrel-type churn which may be made of either wood or metal. Metal churns were perfected after World War II and are most desirable because they are easily sterilized. Churning consists in agitation of the cream until the microscopic fat globules clump together as butter granules which separate from the liquid portion. The liquid (buttermilk) is drained and the butter is washed with sterilized water. Salt may be added after the wash water has been drained and the butter granules are worked into a uniform compact mass of butter which must contain at least 80% fat. The conventional churn handles cream in 1,000- to 5,000-lb. batches. Continuous churns, which were developed in Europe prior to World War II and in the United States immediately thereafter, produce 1,000 to 2,000 lb. of butter per hour.

**Cheese Making.**—Cheddar cheese, one of the most popular varieties, is made from whole milk which may be either raw or pasteurized. Cheese curd is formed by the action of rennet extract, an enzyme preparation, upon the main protein constituent, casein. After the curd has been formed, it is cut into small cubes, stirred and heated so as to expel the whey. Bacteria which are added to the fresh milk produce lactic acid. This in turn also aids in whey expulsion as well as in control of flavour in the ripened cheese. After the curd has firmed properly, the whey is drained and the curd is allowed to fuse together on the bottom of the vat. Following this step, the slabs of curd are cut into small pieces for uniform salting. The curd is then put into hoops and molds and pressed into the desired shapes in a hydraulic press for 12 to 18 hours. Aging takes place at approximately 50° F. for one month to a year. Cheddar cheese, to have a well-ripened flavour, should be aged six to nine months.

BY COURTESY OF CHERRY-BURRELL CORP.

FIG. 5.—CONTINUOUS SYSTEM OF BUTTER MANUFACTURE

There are 18 distinct varieties of cheese with about 500 names. Cheese has frequently been named for the locality where it was made and not because it was a unique variety. Although cheese is made in almost all parts of the world, the varieties that are common in the United States are of European origin. They have come mainly from England, France, Italy, Germany, Switzerland, Belgium, the Netherlands, Denmark, Norway and Sweden.

Processed cheese originated in the United States and Switzerland almost simultaneously. This cheese is a blend of several different lots of the same variety, such as cheddar or swiss. These are shredded, mixed and heated to 160°-165° F. in the presence of a small amount of an alkaline solution.

**Ice-Cream Manufacture.**—Ice cream has perhaps more popular appeal the world over than any other dairy product. Technological developments since 1900 have exerted a profound influence on the manufacture of ice cream. The industry which started in a modest manner with a tub freezer using salt and ice has progressed to the stage where automation is more extensively developed and applied than in any branch of the dairy industry. The invention of the homogenizer, mechanical refrigeration, stainless steel, high-temperature short-time pasteurization and modern transportation equipment have each contributed to the development of ice-cream manufacture. Automatic weighing and blending of ingredients, *i.e.*, cream, concentrated milk, fresh milk, liquid sugars and stabilizers, followed by continuous pasteurization at 220° F. or higher, continuous freezing and continuous tunnel hardening at -40° F. make it possible to complete in two or three hours a process of manufacture that formerly required two or three days.

Distributing ice cream in grocery stores and supermarkets was a post-World War II marketing development and an important factor that contributed to increased consumption of ice cream.

#### DISTRIBUTION OF DAIRY PRODUCTS

The distribution of dairy products is almost world-wide. Improvements in production and processing techniques have made it possible to keep milk in fresh condition for many weeks and to ship it around the world. All-weather roads and transport vehicles have widened markets through bringing milk hundreds of miles from regions of heavy or surplus production to areas of deficient supply. A marked trend beginning in the 1940s and continuing in the second half of the 20th century has been increased sales of dairy products through stores and a smaller proportion of the total sales through deliveries to homes. The use of milk has been promoted through the placing of vending machines in factories, office buildings and convenient outdoor locations. Much milk also was distributed for use in school lunch programs.

In nations having an advanced dairy industry, distribution of milk in bottles or cartons is the general practice but in some other countries milk is carried in bulk to homes and dispensed into containers provided by the housewife. In many cases the milk distributed in bulk lacks the benefits of refrigeration and pasteurization.

#### GOVERNMENT SUPERVISION AND INSPECTION

Regulations aimed at providing sanitary procedures in the production, processing, storage and distribution of dairy products, as well as standards prescribing food composition, have been established by several levels of government in countries having an advanced dairy industry. In the United States prices paid for fluid milk to producers in many of the major milksheds are regulated by federal milk-marketing orders. The milk dealers and handlers of a local area are required to pay certain minimum prices for the various use classifications. The portion used for fluid milk and cream receives the highest price and manufactured products receive lower prices. The orders do not fix retail prices.

#### ECONOMIC DATA

**Employment and Labour.**—The scarcity of farm labour which began during World War II, together with higher costs in other phases of milk production, impelled United States dairy farmers to reduce the amount of hired labour to a minimum. High production of milk per farm worker is recognized as an economic

advantage and goal just as is high milk yield per cow. To this end, labour-saving machinery including such items as forage harvesters, silage choppers, automatic feeders and waterers, barn cleaners, pipeline milking machines, bulk milk coolers and bulk milk pickup at the farm found increased use and replaced much hired labour. A large amount of family labour is utilized to advantage in the care of dairy cattle, especially the help of children before and after school hours. In the second half of the 20th century, however, in spite of a reduction in the number of cows and increased use of machines, more than 2,600,000,000 man-hours of labour were expended on milk cows in the United States in a single year and dairy products were handled in 11,000 dairy establishments which had 280,000 employees. Thousands of other persons were engaged, during at least part of their working time, in the handling of dairy products in transportation, industry and food stores and services.

**Farms and Milk Cows.**—Of 791,000,000 head of cattle reported in the second half of the 20th century, 100,000,000 were classed as milk cows, with the following distribution: Europe 39,000,000, North America 27,000,000, Asia (India and Pakistan) 26,000,000, Oceania (Australia and New Zealand) 5,000,000 and Africa 3,000,000.

The agricultural census of the United States (1954) showed 2,936,000 farms keeping milk cows or 1,700,000 fewer farms than five years earlier. Those which had sales from the dairy enterprise comprising 50% or more of the total farm sales were classed as dairy farms and numbered 548,763. On 70% of the farms the herds contained from 1 to 9 cows, forming 27% of the total cows; on 12% of the farms, each herd had 10 to 14 cows, comprising 16% of the total; while the remaining 18% of the farms with herds numbering 15 or more cows had 57% of all milk cows. The average number of cows per farm was 6.9 as compared with 5.8 reported in 1950. Sales of milk per farm rose to 87,600 lb. from 62,500 lb. in 1949. In the second half of the 20th century the trend was toward fewer dairy farms, larger herds and higher production per cow.

**Amount of Production.**—New Zealand in the second half of the 20th century was the most intensive dairy country in the world when milk production per capita was used as the yardstick. Other countries with high production per capita were Denmark, Ireland, the Netherlands, Finland, Australia and Switzerland. Among the countries for which dependable statistics were available, the United States led in the total production of milk, butter, cheese, canned milk and dried milk. The Federal Republic of Germany and France were second and third, respectively, in total production of butter while Italy and France held second and third places in the total production of cheese. The Netherlands was second and the Federal Republic of Germany third in the total production of canned milk. Of a world production, not including the U.S.S.R., of more than 269,000,000 metric tons (over 297,000,000 short tons) of milk, 90% consisted of cow's milk, 5% buffalo milk (principally in the far east), 3% goat milk and 2% sheep milk. Of the reported total world milk supply, European countries produced about 46%, North America produced about 24% while the production figures for Latin America were 7%, the near east 5%, the far east 11%, Africa 3% and Oceania 4%.

**Exports and Imports.**—New Zealand, Denmark, Australia, the Netherlands and the United States were leading exporters of butter and cheese. The Netherlands led in the exporting of condensed milk and the United States in the exporting of milk powder. Argentina was a leading exporter of casein. The United Kingdom, the principal importer of dairy products, in the second half of the 20th century became an exporter of condensed milk. Immediately prior to World War II the United States exported 2,000,000 to 3,000,000 lb. of butter and 1,500,000 to 2,000,000 lb. of cheese yearly. During the war years the amounts exported reached 100,000,000 lb. of butter and 150,000,000 to 300,000,000 lb. of cheese. In the second half of the 20th century large quantities of butter, cheese and nonfat dry milk were shipped abroad under various aid programs. Total shipments, including exports, in one year reached 180,000,000 lb. of butter, 174,000,000 lb. of cheese and 600,000,000 lb. of nonfat dried milk. Cheese imports amounted to about 54,000,000 lb. yearly.

**Income.**—Yearly cash receipts of United States farmers from marketings of milk and cream in the second half of the 20th century formed 14.6% of all farm marketings and totaled nearly \$4,500,000,000. About 88% of this came from milk sold to plants and dealers, 7% from cream sold to plants and dealers and 5% from sales of milk and cream retailed by farmers. Not included in these receipts was an item of \$500,000,000, the estimated value of milk and farm butter used for farm consumption. Dairy farmers also received an estimated \$1,250,000,000 from the sale of dairy cattle. The farm value of products sold represented the following approximate proportions of the retail prices: fluid milk 45%, butter 70%, cheese 50%, evaporated milk 45% and ice cream 20%.

**Location of Industry.**—In the United States milk cows are kept in all states. Those having the largest number of farms keeping milk cows, as reported in the 1954 census of agriculture, were Texas, Missouri, Tennessee, Iowa, Kentucky and North Carolina. However, the average number of cows per farm in these states was small. Dairy farmers in each of six states, Wisconsin, New York, California, Pennsylvania, Minnesota and Ohio, received yearly more than \$200,000,000 cash receipts from marketings of all milk and cream. Farmers in each of six other states, Michigan, Illinois, Iowa, Texas, Indiana and Missouri, received more than \$100,000,000 cash receipts from such marketings. Small creameries and cheese factories in rural communities have largely been replaced by centralized processing plants in urban centres. Plants with the largest total capacity are located in or near large cities.

(W. B. N.; S. L. T.)

**DAIS**, originally the raised part of the floor at the end of a medieval hall. On this the lord of the mansion dined with his friends at the high table, apart from the retainers and servants. There was generally a deep-recessed bay window at one or at each end of the dais to give greater privacy than the open hall could afford. In France the word is understood as a canopy (q.v.) or hanging over a seat, probably from the fact that the seats of great men were often surmounted by such a feature. In ordinary usage the term means any raised platform in a room, for ceremonial use.
